It is also to be borne in mind that there is not a single woman who becomes a mother for the first time, either high or low, who understands the proper management of infants; and hence the mortality of first children is very great, in fact few of them survive. There is, however, another cause of mortality, and it is the injury inflicted on the fœtus in utero by mismanagement during pregnancy, tight lacing, too much exercise, &c., and the compression it sustains during parturition. This last cause accounts for the great proportion of still-born infants, and of those that are delicate and seldom survive. In general there is more difficulty experienced in a first than in any subsequent parturition; and as male infants are usually larger than female, the mortality is greater among them. Dr. Clarke of Dublin has adduced ample proof of this statement. "It appears by a table kept in the Dublin Lying-in Hospital for 27 years, from 1757 to 1784, there were 20,117 infants born, of which the males were to females as 9 to 8, and 1 in 30 was still born. There were 10,647 males, and 9,470 females. At the end of a fortnight the balance in favour of the boys, originally 1177, was reduced to 483, being a greater loss of males to females, by 694." Dr. Clarke is of opinion that the male head is in general larger than the female, and consequently more compressed during labour. The still-born infants were in the following proportions in the different cities, according to Mr. Robertson: 1 in 24 in London and Vienna; 1 in 36

Stockholm; 1 in 19 Dresden; 1 in 33 Brunswick; 1 in 15 Hamburg; 1 in 19 Paris; 1 in 11 Strasburg.

From the preceding facts, it is clear that infantile medicine is not too minute or unworthy of attentive study and cultivation. For my own part I could never perceive the reason why we should not apply the science and practice of medicine to man, from his nativity to the last hour of his existence. In early life he is extremely liable to diseases, on account of the peculiarity of structure, functions, and the delicacy of his constitution. Diseases are more rapidly excited, more difficultly treated, and much more fatal during infancy, than in the other periods of life. The comparative mortality among infants, which will be hereafter noticed, establishes the validity of this position beyond the power of contradiction or doubt. A slight cause will induce local or constitutional irritation, which may rapidly be followed by convulsions, inflammation, and death. Infants cannot bear pain for any length of time without danger to life, and hence all external injuries and surgical operations ought to be carefully avoided; the latter should not be practised unless when the functions of life cannot go on without them. How often do we see cases, in which a slight wound or a burn induces convulsions and death in a few hours, in despite of all remedies.

The greatest judgment is required in the detection and discrimination of infantile complaints, and the greatest caution in the administration of remedies. If medical practitioners encounter such difficulty, it is obvious that those unacquainted with the nature of diseases cannot attempt their treatment with safety. Such persons may exhibit an *aperient* medicine, but nothing else. In this part of the United Kingdom it is a popular opinion, that every infantile disease is caused by teething, water in the head, or worms, and that every old nurse or chemist is competent to treat them. The ignorance and temerity of non-professional persons in this respect lead to the most fatal results. I have known a case, in which a druggist, who styles himself surgeon, gave a mother a fever powder for a child of three years of age, which was seven grains of tartarised antimony; intense vomiting was excited, the "doctor" pronounced this beneficial, the child died in a few hours,—and this person informed a friend of mine, that this was his usual powder for children.

The mortality among infants is much greater among the poor than the rich, for the reasons already stated, and an immense number is annually destroyed in winter. The latter are better fed and better managed, both morally and physically.

Healthful children recover, but those which are puny or delicate generally fall victims to disease. There is a wonderful power in the constitution to ward off diseases, and many of these have a tendency to cure themselves. Some organs are weaker than others, either

acids. One-fiftieth part of a grain dissolved in alcohol suffices to kill a sparrow in a few minutes, and one-tenth of a grain destroyed a little bird with the rapidity of lightning. It dilates the pupil of the eye, but its action is evanescent.

Codeine.

According to M. Barbier, the codeine of M. Robiquet differs in many respects from morphia and opium : an ounce dose, containing a grain of this preparation, administered either in syrup or in an aqueous solution, acts principally upon the nervous centres of the great sympathetic, especially in the epigastric region. In gastralgia, where the patient complains of pain and weight under the inferior end of the sternum, increased upon pressure, perspirations, palpitations, hiccup, nausea, syncope, &c., the syrup is of the most essential benefit, almost always giving relief. This substance generally produces calm sleep, very different from that obtained from opium. It never occasions weight in the head, numbness or congestion of the brain, but appears on the contrary to create exhilarating sensations. At the Hôtel Dieu, at Amiens, M. Barbier has administered it to women who were suffering at the same time from gastralgia and nervous pains in the head, loins, and thighs. The stomach was much benefited by its use, but it did not appear in the slightest degree to exert any influence on the latter.

Appointment of M. Serres.

The Royal Council have confirmed the nomination of M. Serres to the situation of External Clinical Professor of the Faculty of Montpellier. We congratulate at the same time both the Professor and the Faculty, for no person better merits to replace M. Delpech.

Death of Dr. Chevreau.

Dr. Chevreau, Surgeon-in-Chief to the African corps, and an officer of the Legion of Honour, died lately at Algiers, aged 59. A funeral oration was made over his tomb by M. Stephanopoli, chief physician to the same corps.

PETITION OF THE ROYAL COLLEGE OF SURGEONS.

*To the King's Most Excellent Majesty.—
The Petition of the Royal College of Surgeons in London,*

SHEWETH,—That by charters granted by your Majesty's royal predecessors, this College was incorporated for the advancement of surgery, and for the examination of surgeons, with the power of granting them a diploma attesting their ability.

That your petitioners have expended large sums of money in the reception and display, in the preservation and augmentation, of the Hunterian Museum, and in rendering it accessible and useful to the public, so as to advance to the utmost of their power, those great scientific and national objects, which were contemplated by your Majesty's Government and by Parliament in entrusting the Museum to their care; also, in making and constantly increasing a collection of books, not only in all branches of medical science, but in the various auxiliary departments of knowledge, and in opening it freely to the scientific public, as well as to their own members.

That the Museum and Library are attended with a great annual expenditure, entirely defrayed from the funds of the College; and that they could not be maintained in their present state of public usefulness and efficiency if those funds should experience any material diminution.

That in fulfilling the important duties entrusted to them by royal charter, your petitioners have constantly endeavoured to improve the education of surgeons, to advance the healing art, and to uphold the scientific character of the country. They have the satisfaction of believing that these efforts have been successful; they do not hesitate to affirm that the members of this Royal College have contributed very largely to the great improvements which surgery has received in modern times, and that, whether we regard the intelligence and skill of the body generally, or the knowledge and public services of individuals, English surgeons are not inferior to those of any country. The diploma of the College is held in such high estimation by the public, that nearly all who enter the sur-

gical profession consider it indispensable to their success; and its possession is required, almost invariably, as a condition of eligibility to public surgical appointments of all kinds.

Your petitioners, having heard that certain persons, acting on behalf of an institution, called the London University, have applied to your Majesty for a charter of incorporation, with the power of conferring medical degrees, humbly submit to your Majesty, that the grant of such a power to that institution, while it would infringe the chartered rights of your petitioners, would be injurious and unjust to the other medical schools of the metropolis, which your petitioners are bound to protect to the utmost of their ability, from a long experience of their efficiency as instruments of professional education; and that it would consequently be highly disadvantageous to the public.

Your petitioners having heard that the liberation of a large class of your Majesty's subjects, who dissent from the Established Church, from the inconveniences under which they labour in consequence of their exclusion from the English Universities, is alleged as a reason for granting to the London University the power of conferring degrees, beg leave to represent to your Majesty, that no religious distinction is observed in conferring the diploma of this College.

Your petitioners humbly submit to your Majesty's gracious consideration, that the institution which is called the London University, resembles the ancient and venerated Universities of England only in name; that it is, in fact, a joint stock association, established by the subscription of money in shares, which may be bought and sold in the share market. When first opened, it was under the general direction of a Council, and the immediate superintendence of a resident head, called the Warden, and it thus presented to public view the outward semblance of academic arrangement and discipline. These forms have been materially changed, and the office of Warden has been altogether abolished. The institution having spent all the money originally subscribed, has already fallen into pecuniary embarrassments, so that, according to a printed document issued by the Council, the session could not have been opened in October, 1832, without the assistance of a

loan from some proprietors, who have therefore a manifest pecuniary interest in the success of that application for a charter, which they have been particularly active in promoting. It has since been found necessary to raise a further supply by way of mortgage. The consequence is, that the original 100*l.* shares are now at a discount of 75 per cent., so that for the sum of 25*l.* a person may become a proprietor of this institution, and have a voice in the appointment of Professors, and in the granting of the proposed degrees.

Your petitioners humbly submit, that a fluctuating body of shareholders, amounting to above 1000, especially when the shares may be bought for 25*l.*, is unfit, by its very constitution, to exercise the powers now solicited on behalf of the London University; that this establishment, even if its constitution were unobjectionable, is entirely deficient in the essential requisites of security and stability, and can only be regarded as an experiment, of which the result is at present extremely doubtful.

In consequence of the state of the finances, the Council of the University, before the opening of the Session in 1833, withdrew from further pecuniary responsibility, by giving up the control of the Schools in a great measure to the Professors, and receiving from them a guarantee to the amount of the estimated annual expenditure. Thenceforth, therefore, the medical and surgical department of the London University can only be regarded as an Association of Teachers, conducting the School as a speculation of their own, superior in no respect to the other medical schools of London, but inferior to most of them in not possessing the means of that practical instruction at the bedside of the sick, without which a due knowledge of medicine and surgery cannot be acquired. On the other hand, the previously existing schools of surgery, connected with the great hospitals of the Metropolis, possess the advantages of a well organised system of instruction, both in precept and in practice; in them the great body of English practitioners have been educated; and their teachers have attained a degree of celebrity, as public men, to which the high character of English surgery may be ascribed.

Your petitioners, therefore, humbly submit

that the Association of Medical Teachers in the London University has no claim to any superiority of power or privilege over the other medical and surgical schools of London; and that to give to the former distinctions or privileges which are denied to the latter would involve the double injustice of unfair preference and unmerited exclusion.

Your petitioners beg leave to represent, that large sums have been expended in founding and supporting the medical schools of the great hospitals in London, in erecting suitable buildings, and in providing museums, libraries, and the other requisites of professional education; that property to a considerable amount is invested in these establishments, in which gentlemen of abilities, knowledge, and zeal, are employed as teachers. Among these schools, which depend for their success merely on the talents and exertions of their teachers, and on their respective advantages in other points, an honourable competition exists conducive to the promotion of knowledge, and advantageous to the public.

Your petitioners beg leave to express, in the strongest terms, their serious apprehension of the public disadvantage that would result from any measures calculated to derange the present efficient system of medical and surgical instruction; especially from the conferring on any one school a monopoly of power, and thus degrading and injuring the other institutions.

Your petitioners are firmly convinced, that the occupation of teaching, and the power of examining and conferring degrees, ought to be exercised, as they now are, by distinct institutions; and that the union, in one and the same institution, of these discordant attributes, must be attended with danger to the public welfare, on the numerous occasions in which the interest of the teacher and the duty of the examiner would interfere with each other.

Your petitioners therefore most humbly pray that your Majesty will not grant to the Institution, which has assumed the name of the London University, the power of conferring medical degrees; and they further pray, that if the expediency of such a grant should be referred, by your Majesty, to the consideration of your Majesty's most honourable Privy Council, they may have the opportunity of being heard by Counsel on the subject matter of this Petition.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, April 19th, 1834.

MR. PETTIGREW in the Chair.

Abscess in the Thorax.—Artichoke in Rheumatism.—Conferring of Charters on Universities.

MR. PETTIGREW exhibited to the Society a preparation taken from a carpenter, who had died in the Charing Cross Hospital. On the 27th of March, whilst in a state of intoxication, he was knocked down by a carriage, the wheel of which passing over his thorax, fractured four or five of his ribs, and extensively bruised the surrounding parts; when brought into the hospital his pulse was very feeble, and he was still labouring under the effects of liquor: some hours afterwards, reaction having taken place, he was bled; at the end of four days he became much better; his respiration, which was laborious, became easier; there was, however, a slight cough, but he did not complain of any particular pain in the chest. He continued nearly in this state until the 21st of April, when the cough became much aggravated, and the expectoration was of a purulent character; his symptoms continued to grow worse, and at the end of 36 hours he died. The periosteum was found torn from the fractured ribs, which did not show any appearance of reparation; on the pleura costalis there was a large cavity, containing nearly two quarts of purulent matter; the lungs were blanched. This case was interesting, inasmuch as it exemplified the very great extent to which mischief might proceed in the chest, without any symptoms of such disease being excited.

Dr. Johnson thought that abscess in the thorax was much more rare than many medical men were inclined to suppose; purulent depots, which were essentially different, not having any of its characteristic signs, were frequently mistaken for abscess.

Mr. Hunt was not disposed to think that this formation was so rare a disease as Dr. Johnson imagined; at the same time, he thought that those collections of matter, which appeared in the last stage of typhoid fever, &c., were of a different nature, there not being in the constitution at the time sufficient

strength to produce that adhesive margin necessary to the forming of an abscess.

Dr. Epps mentioned a case, where the lungs were found perfectly sound, although during life the diagnosis had been phthisis pulmonalis; coagulable lymph had been thrown out between the pleurae, and had there formed a false membrane.

Dr. Epps sent round some of the extract and tincture of artichoke, to which he had alluded at the last meeting; since that evening he had received two communications on the subject, in one of which the medicine was highly extolled.

Dr. Johnson, understanding that the question of granting charters to Universities was to be agitated this evening, thought he might save the time of the Society, by stating that a memorial had been presented from the London University, praying his Majesty not to grant a charter to that institution, but to confer upon some central body the privilege of granting degrees.

Dr. Epps was rejoiced to hear what Dr. Johnson had just stated, but still he should not, in consequence of what some individuals had done, be deterred from persevering in his resolution. In a speech of considerable length and eloquence, but of which the limits of this Journal will not allow the insertion, he proclaimed against the insufficiency and abuses of the present system of conferring medical degrees, and concluded by moving the resolution which had been read at the last meeting.

This having been seconded by Dr. Johnson,

Mr. Hunt regretted that the present subject should have been brought forward at the present time; the facts of the question being so entirely in the hands of the House of Commons; he thought that many of the grievances alluded to by Dr. Epps were imaginary.

Dr. Johnson agreed with Dr. Epps in the remarks which he had made, with the exception of the necessity of applying to the King at the present juncture: the grievances referred to were not imaginary, and he thought that the voice of the profession should be made known, for the purpose of assisting the parliamentary decision.

Mr. Dewhurst proposed an amendment, the purport of which was diametrically opposed to the original motion.

This not being seconded,

Mr. Greenwood said he felt surprised to

hear Dr. Epps bring forward this question; he did not think that there could be any objection to the granting of a charter; but if that charter entitled them to confer medical degrees, it might act disadvantageously.

Dr. Ryan agreed with Dr. Epps in the propriety of discussing his resolution, because he felt convinced that the Corporation of London were under certain influence, or they would never have advocated monopoly. As to the wishes of the professors not to obtain the power of conferring medical degrees, he thought they would be of little effect, when the Council of the University were anxious to obtain that power, and they were the chief of his Majesty's ministers. Another reason advanced against the present resolution was, that a Parliamentary Committee was now engaged on medical education, and the Society ought to wait for its decision. But suppose this decision was not made for six or nine months, and that a charter was granted next week to the University, could the Society express its opinion? He felt convinced that the opinion of the largest medical society in London would have great weight both with the Legislature and Privy Council, and therefore the resolution ought to be discussed. All the profession, who had given evidence before the Parliamentary Committee, the monopolists excepted, approved of the establishment of One Faculty of Medicine, with a power of granting degrees; and many said that this ought to consist of the most eminent members of the Colleges of Physicians and Surgeons, after these bodies were liberalised and modernised, together with other distinguished practitioners, and the lecturers of all the medical schools in London. In his opinion a faculty might be so constituted, provided professors of the elementary branches of the medical sciences were elected by ballot, previously to the examinations for the degree, and by this means the candidates could not know the teachers who would be examiners, and there could not be any monopoly in teaching. It would be absurd to expect that physicians and surgeons in extensive practice would be acquainted with the actual state of the elementary sciences, for example chemistry, and therefore they would be incompetent examiners, though very efficient in practical medicine and surgery. There should be several examinations, as at Paris, or at the Dublin

College of Surgeons, for no one who heard him would admit that an examination of half an hour or less at one place, and of an hour and a half at another, were sufficient tests of competency for the practice of medicine and surgery. There were now many medical schools in London with museums and libraries, purchased at great expense, and it would be manifest injustice to give a monopoly to any one of them.

Dr. Epps replied to all the arguments urged against his motion, and was only surprised that it received such little opposition. He commented upon the amendment, which he showed absolutely contradicted itself, and felt satisfied that the Westminster Medical Society would agree with him in opposing the proposition of conferring an exclusive privilege, a monopoly upon any medical school in the metropolis.

The Chairman then put the resolution, against conferring a charter upon any University in London to the vote, when it was carried by a large majority.

A motion was then made by Mr. Hunt and Mr. Simpson, that a special meeting of the Society should be summoned, to consider the expediency of appointing the officers at the last meeting of the session.

The President announced that this motion would form the matter for discussion on next Saturday evening.

The meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

Monday, April 21st, 1834.

T. E. BRYANT, Esq. in the Chair.

Properties of the Lobelia Inflata—Nervous Influence—Causes of Asthma—Treatment of Hooping Cough.

THE minutes of the preceding evening having been confirmed,

Mr. Roberts read to the Society a paper on the medical properties of the lobelia inflata, a plant lately introduced into this country from America, where it has for some time been used extensively in the cure of asthma and other affections of the chest. After stating that it possessed rather stimulating than narcotic qualities, and, therefore, was not adapted for cases where inflammation existed, but rather to check the morbid action left in the part by such inflammation, and dependent

upon some particular state of the nervous system, he concluded by referring to some cases illustrative of the different states of disease in which it usually proved beneficial.

Amongst other observations elicited from various members by this paper,

Dr. Uwins confessed that he had long considered the bronchitis of hooping-cough very different from ordinary cases of bronchitis, the former requiring a totally different plan of treatment, not being affected, but even benefitted by exposure to changes of temperature, and not being influenced by the medicines which were successful in the latter.

Dr. Whiting did not think, as some of the members seemed to do, that the influence on the nervous system must necessarily be the same in all cases, for according as the agent was different, so would the impression be. The various forms of cutaneous eruptions were caused by the influence, communicated through the nerves, being various; he had observed that some one of these forms of eruption (in general the chronic form of eczema) accompanied asthma.

Dr. Blicke felt convinced that asthma in every instance depended on derangement of the primæ viæ, and might be cured by simply attending to the regulation and improvement of the digestive functions; affections of this kind were, in his opinion, attributable to the acrid state of the blood, in consequence of the derangement of this system, and asthma was nothing more than thickening of the mucous membrane dependent on the same cause.

Mr. Clifton was well aware that asthma, as well as most other complaints, was capable of being much benefitted by attention to diet; but to say that such simple treatment would always suffice for the cure of the complaint, was jumping at once to a conclusion in which his experience would not allow him to coincide. In reference to the remarks of Dr. Uwins, on hooping-cough being benefitted by exposure, he begged to state that he could not agree, having almost invariably found that by keeping the child in one temperature, he could cure the disease, and that by exposing the patient it became aggravated.—Adjourned.

ROYAL COLLEGE OF SURGEONS.

THE Jacksonian prize for 1833 was adjudged to Mr. John Green Crosse of Norwich, for "a

Dissertation on the Formation, Constituents, and Extraction of Urinary Calculus;" and premiums of equal value have been adjudged to Mr. Richard Radford Robinson, of Cowper's-row, Trinity-square, London, and to Mr. George Thompson Morgan, of Queen-street, Aberdeen, for dissertations on the same subject.

THE

London Medical & Surgical Journal

Saturday, April 26, 1834.

HOSPITALS NATIONAL ESTABLISHMENTS.

THE present condition of medical appointments in our metropolitan hospitals will, of course, occupy a large share of the attention of the Parliamentary Committee, in its review of the present state of medicine; and in any project for its reformation there will be much to reform and order in these great practical schools of medicine. In them, all the accidents and diseases, which it is the glory of our profession to relieve, are accumulated for purposes of the purest charity, for the enlargement of the domain of science by the most eminent practitioners of the day, and, what is of equal importance to the public, for the instruction and improvement of the many who are afterwards to dispense their skill and knowledge in a thousand different private channels. Dispensaries, to a certain degree, have corresponding claims to attention:—but many of them are got up as mere advertising machines, and are utterly worthless of notice, except for the sake of exposing the tricks of their composition. There are, however, several of them of great practical importance, and although these latter generally differ from hospitals, in being in a great measure dependent upon annual subscriptions for support;—although they do not offer the advantages of intern patients, whose whole

regimen is at the will of the practitioner; still we look upon them as very valuable instruments for education; and many of the remarks we are about to make, more particularly with regard to hospitals, will apply to respectable dispensaries also.

It will be one of the objects of the Parliamentary Committee to inquire into the funds by which the hospitals of the capital are supported. We are aware that certain questions have already been sent to the proper quarters, which will elicit all necessary information upon this subject. Some hospital worthies have shown an inclination to kick against the interference of a Committee of the Legislature with their *private* affairs;—and we, in our station, are prepared to undergo their indignant remonstrance against our proposed interruption of their established system. Without, for the present, taking the trouble of very minute inquiry, we conceive we are authorised in our statement, that a very large portion of the funds of every hospital in the capital is derived from fixed and permanent sources, and that the free gifts alone of deceased benefactors would go a vast way in maintaining them in their present efficiency. Besides, as to their floating income, much, very much indeed, of that is derived from the public spirit and generosity,—to lay ostentation aside,—of persons of eminent station, who consider they owe a duty to society, for the protection it affords their wealth and rank, to contribute to the maintenance of public charities. These personages are not likely to be influenced in their annual subscriptions by any selfish motive of personal influence in the management of the hospitals, or the appointment of their medical officers.

We have, then, in the metropolitan hospitals, every element of national institutions. True, they are not the gift of the State; they are not supported out of

the general taxation of the kingdom; Government does not interfere in their management:—but they are truly *English* in their origin;—nor are their funds the less national, in that they have been dedicated to the public service in aid of national wants, by the unconstrained liberality of private citizens. And as to their management, they have of necessity become such important parts of our medical polity, as schools and theatres of medical science, that it is idle to talk of usurpation, when we propose to make them essentially integrant parts of the great republic of medicine, and subject to its laws.

Some of these laws it is our present purpose to suggest. We cannot pretend to give a distinct outline of the comprehensive subject, to the proper consideration of which these observations may, it is hoped, contribute. We shall confine ourselves to a few remarks upon certain very glaring defects at present observable in hospital regulations, which might perhaps be remedied by the hospital governors themselves, although we confess our hopes of amendment would be very slight were there not a Parliamentary Committee now sitting.

The first point to which we shall allude relates to the proper period at which an hospital medical officer ought to retire, and give place to other, not to say better, men. The present system of life-appointments is utterly indefensible upon any knowledge of human nature. It is not more true than remarkable, that, sensible as men are in their youth or manhood of the infirmities of age, they seldom discover these infirmities in themselves as age creeps on apace, till they have in their turn been a spectacle to the youth or manhood of another age. Even in pure medical practice the defect of age is felt; after a certain age a man is deaf

and blind to all improvements in his art. There are certainly rare examples of minds vigorous and elastic to the very verge of a long life: but rules must be laid down for average cases. In surgical practice, in the serious matter of operative surgery, it is shocking to behold the tremor of a hand, unsteadied by time, attempting a public operation, after all private practice of the kind is gone. We shall not record the absurd stories which those who “love a joke” repeat of certain miserable exhibitions of hospital octogenarians. Our aim is a reform of a palpable abuse. But the evil inflicted on the sufferers by such practitioners is small compared with the mischief their tenacity of office inflicts upon young men, who are excluded thereby from the advantage of hospital practice at the time it is most likely to be serviceable to them, while the public is debarred from the advantage of so much additional medical skill. The proposition we are advocating, of setting proper limits to the duration of a hospital appointment, has been admitted as most reasonable by many in authority. Some of them, whose promises we have, are still in their vigour; others have admired the principle, but have forgotten its practical application in their own case.

What should be the limit, whether sixty-five or sixty, is another question. We are disposed towards the shorter term. After a surgeon or physician attains *that* age, he cannot expect to improve his practice.—It will be well if he retains what he has. It is not, however, to be concluded from our suggestion for calling younger men into active operation, and employing them publicly while their faculties are unimpaired, that we desire to sever the connexion between eminent practitioners in advanced life,—whose services have been appreciated, who have

had their day,—and our national establishments. If their talents merit the honour, there may be reserved for them the graceful situation of consulting practitioners; and as such, without detriment to the charitable interests, or obstruction to their brethren, they may yet do good service after their retirement.

Suffrages will be more divided upon another proposition touching the same subject.—Every person not of the standard age will agree in the last.—The suggestion on which we expect opinions will be divided, because it is levelled at a monopoly, is this:—That it is desirable for the interest of medical practitioners in the metropolis, and for the interest of the public, which is deeply concerned in their available skill, that the medical officers of the national hospitals should be extended much beyond their present number; and that they should be employed according to some system of rotation in discharging their important duties. A rotation of this kind exists in some of the Continental hospitals. It seems to us an excellent expedient for giving the public at large the benefit of the knowledge to be acquired by hospital practice; and the competition it would produce in regularity and in study, by opening, as far as it is possible, the road to eminence,—by allowing unpatronised talent to make its way before the public,—would contribute to the cultivation of medicine, in a manner scarcely known in this country, as a science, above all others, worthy of public patronage.

We must leave the subject of the proper manner of appointment of hospital medical officers for the present untouched. It must now suffice to say, that those who adopt the principles of this article will not differ from us when it is convenient to discuss that branch of the subject.

UNIVERSITY OF LONDON.

WE have received a pamphlet* in support of the application of the University of London for a charter, which appears to be intended as a supplementary brief to counsel. The question at issue, will, in the course of this week, have been argued before the Privy Council. Our opinion upon the impolicy of granting to the University any peculiar privilege in medicine is already well known; and we see nothing in the pamphlet before us to induce us to change our well-considered conclusion. We had intended to repeat our observations upon the present occasion; but, as our readers have the substance of Dr. Epp's speech, in another part of this Journal, we shall reserve ourselves for another occasion, being convinced that the Privy Council will never accede to the preposterous demand of a Medical Faculty, with power to grant Degrees, whilst the House of Commons has the whole subject of medical polity under its consideration.

ANATOMY BILL.

THE following petition has been presented to the House of Commons by Mr. Warburton:—

The Humble Petition of the undersigned Medical Practitioners and Students,

Sheweth,

That the act passed by your honourable House in August, Anno Domini 1832, entitled "An Act for regulating the Schools of Anatomy," does not provide for a registry of the names of all the students attending the anatomical classes in the metropolis.

That the only public register known to your petitioners is that at Apothecaries' Hall, (by which the inspector is at present instructed to act); but which merely comprehends those pupils who intend to undergo an examination by that corporate body, exclusive of numerous

* Address from the Senate to the Council, &c. Taylor, London: 1834.

pupils who do not wish to become licentiates of the said corporation; but who dissect for the purpose of passing their examinations at the Royal College of Surgeons in London, or at the Army or Navy Medical Boards; and consequently the above-named register affords no just estimate of the number of pupils absolutely requiring dissection in London.

That the aforesaid Anatomical Bill does not nominate any specific sources whereby the students shall be legally furnished with a supply of subjects for dissection; that at present the principal or sole supply is from the parish workhouses; that the law, at the same time, leaves it optional with the parish authorities whether the unclaimed bodies under their control shall be lent for dissection or not previously to interment; and allows, moreover, the parochial directors to exercise a power of election over the schools, in sending the said bodies to any particular school or schools they may wish pre-eminently to favour.

That the large medical schools or public institutions necessarily possessing more local parochial influence than the smaller anatomical classes, a greater reciprocity of interest and private feelings exist between the teachers of some schools and the parochial authorities, than between the latter and other anatomical teachers.

That in consequence of the above facts, there has not only been a scanty general supply of subjects, but a corrupt exercise of the anatomical law, by the disposable bodies having been very unequally distributed, so that in some schools dissection has been repeatedly suspended, to the immense injury of the teachers, students, and perhaps to the community at large.

That although the Right Honourable the Secretary of State for the Home Department has, by his patriotic exertions and judicious negotiations with the parochial authorities, temporarily moderated the complained of evils, the latter still continue to exist in a material degree; and your humble petitioners fear they will remain, until it may seem to your honourable House needful to make the following amendments in the Anatomical Bill, which they humbly suggest for your consideration.

1st. That proper sources shall be legally established for the supply of subjects for dissection.

2nd. That it shall be legally imperative upon the inspectors, or some other persons, as a part of their principal duty, to distribute equitably, according to the number of students in each school of anatomy, the disposable bodies.

3rd. That the books in which the said bodies are registered shall be open at certain times of the day for the inspection of any person, upon leaving his card or address.

4th. That it shall be criminal to sell or purchase dead human bodies.

5th. That a general registry of all the pupils attending anatomical lectures in the metropolis shall be kept at the College of Surgeons, or some other public institution.

6th. That all the bodies disposable for dissection shall be equitably distributed to the various schools, or other licensed places, through the medium of the inspectors.

Your petitioners therefore humbly pray that your honourable House will institute an inquiry into these facts, or lay them before the Committee now sitting on the state of the medical profession, for the purpose of deciding whether it would not be more advantageous to the interests of society, the profession, and science, to adopt the amendments herein respectfully submitted.

And your petitioners, as in duty bound, will ever pray, &c.

GLASGOW ROYAL INFIRMARY.—CASES OF THORACIC ANEURISM.

BY JAMES DOUGLAS, ESQ.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—Every one who has studied auscultation, is aware that the immortal discoverer of that mode of exploration considered it, even in combination with general signs, inadequate to the detection of thoracic aneurisms. Subsequent observers have thought that they have succeeded better in their diagnosis; and Dr. Hope, in his valuable work on the heart, assures us that he has made out “unequivocal criteria.” I shall notice, first, the sounds of aneurisms, and how they are confounded with the sounds of the heart, then the supposed criteria, and, lastly, two cases, which, with several others where aneurism was diagnosed and not found, have convinced

me that we cannot be certain of the existence of a thoracic aneurism, unless it can be actually seen and handled.

When we place the stethoscope over an artery, we perceive a simple beat, synchronous with the impulse, stronger in proportion to the size of the vessel submitted to examination. In an aneurism, the same thing occurs, as if the artery were still further increased, the impulse becomes stronger, and the sound also. But an additional circumstance is superadded, a bellows murmur, generally very hoarse, and passing into the *bruit de râpe*. In cases of sacculated aneurism, it is easy to conceive how this sound is produced, by the blood passing from the artery through a narrow opening into a large sac; but in cases of simple dilatation, it can be accounted for only by the reflexion of the fluid from the walls of the sac, so as to form conflicting sonorous currents. The sound is generally simple, and accompanies the dilatation of the artery. Yet I have observed it, in a case of sacculated aneurism of the abdominal aorta, to occur later than the impulse, as if caused by the contraction of the sac forcing the fluid out again through the aperture into the vessel. In this way, of course, must be explained the second sound, where the aneurismal sound is double.

In the abdomen, or over any external artery, the existence of a pulsating tumour, with the sound above described, sufficiently indicates the existence of an aneurism; but in the chest, the action of the heart interferes with the diagnosis: for the first sound of the heart is synchronous with that of the aneurism, and the second sound of the heart is heard along with the aneurismal sound, and makes it appear double also. Dr. Hope says, first, that the first aneurismal sound is invariably louder than the healthy ventricular sound, and generally than the loudest bellows murmur of the ventricles; secondly, that it decreases on leaving the aneurism, while the ventricular sound gets stronger; thirdly, the diastolic sound actually does get stronger as we approach the heart; and, fourthly, that the aneurismal sound is deep and hoarse, with an abrupt commencement and termination. Such are his criteria. Now, the second of these appears to me to be too nice for ordinary ears, and the others, though un-

doubtedly good, where there is sufficient distance between the heart and the aneurism, require such a separation to exist, as may give the idea of two centres of motion. The following case exhibits a falsification of the stethoscopic diagnosis, from the *situation* of the aneurism, of which I have not seen an instance in any work which I have had an opportunity of consulting.

John Fyfe, æt. 43, a porter, admitted Dec. 20th, 1833; complains of weakness across the small of the back, and inability for exertion. If he walks, or in any way exerts himself after taking food, it is rejected by vomiting. No pain excited by pressure over the stomach. Complains of breathlessness, but respiratory murmur seems pretty good; action of heart rapid and violent, heard over both sides of the back; ventricular systole accompanied by bellows murmur; pulse 100; tongue white; respiration slow. He was bled to relieve the palpitation, and to ascertain the state of the blood, which was healthy, and was put on tinctura digitalis. Urine, however, became scanty, and by the 30th there was general œdema. By the 9th of Feb., under the use of diuretics, this disappeared entirely, and he felt more comfortable than for many weeks previous. On the 4th of March, 1834, the following entry was made in my case-book:—"Complains much of palpitation; action of the heart for the first time observed, irregular; pulse 60; impulse of the heart very strong, raising the head from the chest, and felt over a space about three inches square: first sound protracted, and accompanied with *bruit de soufflet*,—second, scarcely audible. Sounds heard loudest and impulse strongest under the cartilages of the ribs, and less under the sternum: also heard pretty distinctly on both sides of the back. Carotids are seen to pulsate as far as the angle of the jaw. Diagnosis—Hypertrophy of the left ventricle, with some dilatation.

On the evening of the 4th he fell down when in the water-closet, and died soon after being carried to bed.

Inspection.—On removing the dura mater a quantity of blood was found effused over the anterior part of the right hemisphere of the cerebrum; right ventricle filled with coagulated blood, but no ruptured vessel could be

detected. The heart was very slightly, if at all, hypertrophied. Lying exactly behind the heart was discovered a large aneurism, springing from the posterior part of the thoracic aorta. The sac was about four and a half inches long by three and a half wide, extending from the seventh to the eleventh dorsal vertebrae, and communicating with the aorta by a circular opening, upwards of an inch in diameter, with a thick rounded edge, exhibiting a duplicature of all the coats. They were all traced over the sac to near the back part, where the eighth, ninth, and tenth dorsal vertebrae were in contact with the blood, and deeply carious. A large laminated coagulum had been here deposited.

Below the sac, the aorta, which passed in front of it, was contracted; and about an inch farther down, immediately on passing the diaphragm, gave origin to a small globular aneurism, about an inch and a half in diameter, from its fore part, by an orifice rather larger than a common quill. From the lower and anterior part of this sac, which was a true aneurism in its whole extent, and contained a coagulum, the coeliac axis arose. The coats of the aorta exhibited numerous atheromatous patches.

Here, then, to my astonishment, was a diagnosis falsified, founded on all the physical signs of hypertrophy, in which several excellent stethoscopists coincided with me. The aneurism, from its position exactly behind the heart, had jolted it forward against the parietes of the chest at each systole, producing the apparently tremendous impulse. The reason why the sounds were heard on the back, simulating dilatation, was also obvious. The caries of the spine, which in one place penetrated nearly to the canal, was undoubtedly the reason of the weakness in his back, and the apoplexy was, I suppose, the effect of the retardation of the current in the aorta, by the contraction below the great sac. It is curious that there was no irregularity of the pulse till two days before his death, and that without any assignable cause.

The second case shows how the signs, both general and physical, may be marked by a concomitant affection of the lungs.

Thomas Reid, æt. 54, admitted December 20th, 1833. A fortnight ago, after undue

exposure to the weather, was seized with cough and dyspnoea, aggravated by lying on the right side. Expectoration is copious, consisting of tough mucus, exhibiting some rusty stains, and is brought up with difficulty, especially in the morning. On examination with the stethoscope, the bronchi are found much loaded, and copious, sonorous, sibilant, and mucous râles are heard all over the chest. The rattling of the mucus in the bronchi may be felt even by the application of the hand to the chest. Pulse 96; respiration 24; tongue pretty clean; bowels open; skin natural; voice very hoarse.

Has been subject to cough and dyspnoea, and had a severe attack of this kind last spring.

Sumat. pulv. ipecac. gr. xv. pro emetica.

Utatim mistura scillitica.

Vomit operated with relief of dyspnoea, and the expectoration became easier. Pains, however, were felt in the chest, which were relieved by blisters. Hoarseness continued; and on examining the larynx, the cricoid cartilage seemed nearer the sternum than it ought to be. Calomel, digitalis, &c., were employed, and one night he was nearly suffocated with tough expectoration, but obtained relief by another emetic. Dyspnoea continued to increase, and he died on the evening of the 2nd of January.

The case had been considered one of chronic bronchitis, with an acute aggravation, and was treated as such. Emetics, of course, would never have been thought of, had there been the least suspicion of an aneurism, as they have induced rupture of the sac, and immediate dissolution. But from the loud and constant bronchial râles, no signs of lesion of the heart or aorta were discovered by auscultation, though the chest was frequently explored. The dyspnoea was referred to the chronic bronchitis, but the dissection showed why it was aggravated when he lay on the right side, the left not being occupied by the lung alone. The hoarseness was referred to inflammation in the trachea, although the position of the cricoid cartilage might have led to suspicion, but it was overlooked.

Inspection.—The lungs when cut into, poured out a large quantity of bloody serum, and the divided bronchial tubes contained much muco-purulent matter. The mucous membrane of the tubes was red and thickened;

the cartilages of the larynx were ossified, but still moveable, and the lining membrane was natural. The right ventricle of the heart was found dilated; an enormous aneurism by dilatation of the arch of the aorta, was discovered, rising upwards, attached to the trachea, and passing to the left side, involving the origins of the great vessels, and of much the same volume as the heart itself. It gradually subsides into the natural size of the vessel, about three inches above the diaphragm. The internal membrane is continued all along the sac, except at several rough spots posteriorly, where it would probably soon have burst. A large laminated coagulum is here deposited. There are numerous atheromatous patches between the internal and middle coats of the vessel.

WESTMINSTER HOSPITAL.

Election of Assistant-Surgeon.

THE election took place at the board room of the new hospital. The candidates were Mr. Hale Thompson and Mr. J. Maitland. A large number of governors attended, who expressed their admiration of the beauty of the new building. At the close of the poll the votes were—

For Mr. Thompson 169

For Mr. Maitland 100

LONDON UNIVERSITY CHARTER.

It appears, after all, that the Council of the London University are most anxious for a charter to confer degrees in the arts, sciences, and medicine. We feel convinced that the power of granting medical degrees will be withheld.

HÔTEL DIEU.

Imperforation of the Anus in an Infant two months old—Operation—Cure.

On the 4th of March an infant of the above age was brought to M. Caussade, apparently in a dying state. It vomited fæculent matter, had hiccup, a small thready pulse, livid countenance, and distended abdomen. On examination it was discovered that the anus was deficient, there being only a small capillary

opening at the posterior part of the vulva; through which the infant voided, with great difficulty and pain, a thick yellow-coloured fluid. To remedy the imperforation, M. Caussade made an incision, three or four lines deep, over the part which the anus should have occupied. At the bottom of the incision a mass of fæcal matter was found, and, after some difficulty, on account of its hardness, removed. Injections were then administered, and brought away large quantities of similar substance. The wound was kept open by means of pledgets of lint; and, on the following day, the fæces passed easily through their legitimate channel. No bad symptoms followed the operation, and the juvenile patient is now quite recovered.—*Gazette des Hôpitaux.*

Accidental Hæmatemesis followed by Amaurosis.

A peasant, æt. 45, accustomed to endure great bodily fatigue, and to indulge in spirituous liquors, was seized, after walking a long distance and drinking a considerable quantity of cold water, with vomiting of blood to so great an extent, that on the following day M. Revolot found the patient in so enfeebled a state that he despaired of his recovery. The hæmorrhage continued; the pulse became small; the skin cold; and he complained of intense pain and weight in the epigastric and hypochondriac regions. Acidulated ptisans, to which was added extract of rhatania, were given to him; and he was directed to remain perfectly motionless. By degrees the vomiting and hæmorrhage ceased, but he was then seized with amaurosis, which terminated in total blindness. It was supposed that when the strength of the patient increased, the blindness would terminate; hitherto such has not been the case however.

HÔPITAL ST. ANDRÉ DE BORDEAUX.

Fistula Lachrymalis caused by accidental Inflammation of the Eyelids.

Jeanne Lalande, aged, admitted into this hospital for ulcers on the legs, was attacked in the month of December with ophthalmia. The eyelids became swollen; there was a great secretion of pus; and finally, large abscesses formed at the angles of the eyes: on one side they rapidly got well, but on the other a fistula

lachrymalis formed. Notwithstanding the application of different topical remedies the fistula remained, and caused such severe symptoms, that M. Moulinié plunged a sharp-pointed bistoury into the nasal canal, and then introduced a small catgut bougie, which he left in the wound for twenty hours, after which it was removed. The inflammation rapidly disappeared, the fistulous opening cicatrised, and at the end of a month the cure was complete.

BOOKS.

THE Principles and Practice of Obstetrics, as at present taught by James Blundell, M.D., Professor of Obstetrics at Guy's Hospital. In five parts—I. The Anatomy of the Female System. II. The Physiology of the Female System. III. The Signs and Diseases of Pregnancy. IV. The Art of Delivery. V. The After Management of the Puerperal State, the Diseases of Puerperal Women, and Strictures on the Diseases of Children. To which are added Notes and Illustrations. By THOMAS CASTLE, M.D., F.L.S., Member of Trinity College, Cambridge, &c., &c. 8vo. pp. 838. London: 1834. Woodcuts. E. Cox.

The Natural History of Animalcules: containing descriptions of all the known species of Infusoria, with Instructions for Procuring and Viewing them. Illustrated by upwards of 300 magnificent figures on steel. By ANDREW PRITCHARD, Esq. 8vo. pp. 194. Plates. London: 1834. Whittaker and Co.

An exceedingly interesting volume.

Essai sur la Leucorrhée, et les Causes Diverses qui la produisent. Par M. A. M. BUREAUD REOFREY, M.D., &c. 12mo. pp. 161. A Londres, chez J. B. Baillière.

A Refutation of some Mis-statements Reflecting on the University of Edinburgh. 8vo. pp. 23. Edinburgh: 1834. MacLachlan and Stewart.

CORRESPONDENTS.

G. T. D. will find the matter in the last volume.

A. Z.—It is said that the North London Hospital will be opened in October next, and that the fee for medical and surgical practice will be £15, which will be devoted to the support of the Institution.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXXVII., DELIVERED APRIL 15, 1833.

GENTLEMEN,—I have next to speak to you of *iritis*. When you recollect that the iris receives its supply of blood by the two long ciliary arteries, the external and internal, which are but little connected with the arteries of the other textures of the eye, you must perceive the reason why inflammation of this organ should frequently exist as independently of inflammation in other parts of the eye, as those cases which are termed conjunctivitis, sclerotitis, and corneitis. I wish you also to be aware, that the danger of iritis chiefly depends upon its partaking of the nature of the adhesive inflammation, by which the pupil is apt to become, under the least neglect, completely and irremediably obliterated by the effusion of coagulable lymph. Iritis is, indeed, attended with a degree of inflammation in the sclerotic coat, the front layer of the capsule of the crystalline lens, and too often with inflammatory action in the choroid coat and retina; yet the iris is plainly the focus of diseased action, the affection commencing on its pupillary margin, and other parts becoming subsequently affected by continuity or sympathy.

Iritis, gentlemen, is divided into *idiopathic* and *symptomatic*, *acute* and *chronic*, and into several specific varieties, as I shall presently explain. Certain common symptoms characterise iritis, however, from whatever cause it may originate.

1. In the early stage you may discern minute red vessels, running in radii in the sclerotics to the edge of the cornea, where they form a red zone, while the rest of the sclerotics retains nearly its natural paleness, though it afterwards becomes uniformly red. In this coloured engaving, you see the disease

in a very early stage; there is a zone round the cornea; but the rest of the sclerotic coat exhibits scarcely any redness.

2. Then, gentlemen, another symptom, common to every iritis, is a change of colour in the iris: if naturally blue, it turns greenish; if dark coloured, it changes to a reddish-brown. This is owing to a deposition of lymph in its texture, and to the effusion of such lymph upon its surface. Hence, you frequently notice irregular tubercles, or masses, formed either at the edge of the pupil, or upon the iris itself.

3. Another symptom, noticed in every iritis, is a tendency to contraction, irregularity, and immobility of the pupil.

4. Then, gentlemen, you will commonly also remark an effusion of lymph into the pupil and posterior chamber, and sometimes into the anterior. In rheumatic iritis, however, lymph is more sparingly effused than in venereal iritis.

5. Considerable intolerance of light is another effect of iritis in general; but it is much greater in rheumatic than syphilitic iritis.

6. One thing, which you must not forget, is a disposition in every iritis to the production of adhesions between the pupillary margin of the iris and the capsule of the lens; and sometimes between the iris and cornea, or even between the posterior part of the iris and the ciliary processes. Such adhesions are usually of a dark colour, like that of the edge of the uvea.

7. Together with these common effects of iritis, the patient has dimness of sight, and sometimes total blindness.

8. Pain in the eye, the orbit, and forehead, are likewise invariable attendants on iritis, and often subject to nocturnal exacerbations.

Notwithstanding what I have now stated, when amaurosis exists, iritis may present a dilated pupil.

Next, gentlemen, with regard to the causes of iritis, I may observe, that exposure to atmospheric changes, very strong light, syphilitic disease, scrofula, gout, rheumatism, wounds of the eye, may each be concerned. Iritis, I have said, may be *acute* or *chronic*. When acute, the inflammation, beginning on

the pupillary margin of the iris, quickly extends over its whole surface, and affects the external as well as internal tunics. In chronic iritis, the inflammation sometimes begins at the ciliary margin of the iris, whence it may be slowly propagated to other internal textures. Chronic iritis, however, also sometimes produces effusion of lymph, and adhesion of the edge of the iris to the capsule of the lens, without any perceptible inflammation of other textures of the eye. Between this slowly creeping chronic iritis, and the most acute form of it, you will meet with numerous other cases, in which every gradation of the inflammatory process is exhibited.

The constitutional disturbance is different in different cases. Acute iritis is generally attended with headache, restlessness, full and strong pulse, white tongue, thirst, loss of appetite, and costiveness. At the same time, it must be confessed, that in some cases which would be regarded as acute, such symptoms prevail only in a slight degree.

What am I now to say of *syphilitic iritis*? It is indicated by tubercular depositions of lymph, a reddish-brown discoloration of the inner circle of the iris, the nocturnal exacerbations of pain, which is felt either in a much slighter degree, or not at all, during the day, the previous occurrence of syphilis, and, in most instances, the concomitant existence of other syphilitic symptoms. Then, there is an angular disfigurement of the pupil, which, according to Beer, is usually drawn towards the roof of the nose, but, according to Mr. Guthrie, not more frequently in this direction than others.

In *idiopathic iritis*, there is either no distinct deposition upon the iris, or it presents itself as a bright yellow elevation from the texture of the part, increasing to a certain size, and then breaking, so as to allow the escape of a yellow matter, which sinks to the bottom of the anterior chamber. Such yellow little abscesses you will not observe in syphilitic iritis.

In *arthritic iritis*, or that supposed to be connected with a gouty constitution, lymph is effused from the margin of the pupil, but not deposited in a distinct form, and the adhesions are generally *white*. Both in the *idiopathic* and *arthritic* iritis, the pupil generally retains its circular figure and central position in the iris. In the gouty and rheumatic iritis, a white zone is frequently distinguishable between the red one and the margin of the cornea.

In the *treatment of iritis*, gentlemen, you must attend to three principal indications:—

1. That of putting a stop to the inflammation.
2. That of preventing the effusion of lymph, and promoting its absorption, if it has been already poured out.
3. That of preventing the contraction of the pupil, and the formation of adhesions between the margin of the iris, and the capsule of the lens.

The *first indication*, or that of arresting the

inflammation, is accomplished by antiphlogistic measures: bleeding, saline aperients, and tartarised antimony. If you do not stop the inflammation, it will soon extend to the choroid coat and retina, and sight be endangered. Have recourse then to venesection, or to cupping from the temple and nape of the neck. Sometimes bleeding and the exhibition of sulphate of magnesia, and the tartar. antimony, with other antiphlogistic means, will accomplish the cure of iritis, if duly followed up; but more frequently additional plans are requisite. Antiphlogistic treatment relieves the congestion of the blood in the eye, lessens the redness, and diminishes the fever; but, it does not always succeed in preventing the effusion of lymph, or in bringing about the absorption of what has been poured out.

This makes it necessary to consider how the *second indication*, or that of preventing the effusion of lymph, and promoting its absorption when deposited, is to be fulfilled. Experience proves, that the grand remedy for this purpose is mercury, employed quickly and freely, so as to affect the system. It must be used immediately after bleeding and other means of depletion have been practised. The effect of it is so to change the action of the vessels of the iris, that they lose their disposition to effuse coagulable lymph; and that which has been already effused, becomes absorbed. The natural colour of the iris is restored, the cornea becomes clear again, the red zone round it fades away, and the power of vision returns. All this improvement is rapidly effected, when the system is expeditiously put under the influence of mercury, and here it is advisable to let that influence be stronger than what is usually deemed necessary in other cases of ordinary disease. I generally give two grains of calomel with one-third of a grain of opium every four or six hours.

Then the *third indication*, or that of keeping the pupil dilated, requires the application of belladonna. This must always be preceded by depletion. Other narcotics will produce the same effect, as stramonium and hyosciamus; but belladonna is commonly preferred as most effectual. ℞j. of the extract should be dissolved in ℥j. of distilled water, and filtrated. This preparation is to be dropped once or twice a-day into the eye. But, if the inflammation be acute, it is better, I think, to smear the upper eyelid, forehead, and eyebrow with the extract itself, a little moistened. The other, however, is the most prompt method, if the inflamed state of the eye will bear it, which is not always the case. This use of belladonna is very important, not only as tending to prevent the closure of the pupil, but as keeping its edges away from the capsule of the lens, and even making the iris so withdraw itself from the lens, that, if adhesions be already formed, and the lymph soft, they will give way, and the pupil still recover its natural size and mobility. This beneficial change is also materially pro-

acted by the simultaneous use of mercury. Other local applications are of secondary importance: poppy fomentations generally give most relief, but cold applications may be used, if preferred.

Blisters are not advisable, until the disease becomes chronic; or, at all events, not until bleeding and mercury have been freely practised.

In *arthritic*, or *gouty iritis*, I may say, gentlemen, that mercury is not found so useful as in the idiopathic and syphilitic forms of the complaint. Colchicum and magnesia, and, in the chronic stage, blisters, carbonate of iron, and quinine, are means on which some practitioners place their chief dependence. You should not imbibe the notion, that syphilitic iritis absolutely cannot be cured without mercury. Sometimes it may be cured by antiphlogistic treatment alone; and Mr. Hugh Carmichael, of Dublin, has published a series of well-marked examples of syphilitic iritis, which were cured by giving 3j. doses of turpentine in the almond emulsion three times a-day. Yet he only resorted to this practice when mercury was inadmissible, in consequence of its occasionally injurious influence on the health.

Choroiditis and Retinitis.—The internal inflammations of the eye, gentlemen, may sometimes arise in one texture, and at other times in another; in one case the retina may be first affected, in another the choroid coat, and in a third the iris. From these individual textures, the inflammation may afterwards extend to every part of the eye.

Retinitis is occasionally excited by long-continued immoderate exertion of the sight in the examination of minute microscopical objects, under a strong, and, perhaps, a reflected light. Such cases, however, are generally preceded by determination of blood to the head, or to the eye in particular.

The same consequence may follow the effect of vivid flashes of lightning, or the sudden exposure of the eyes of persons to the light who have long been confined in dark dungeons.

Chronic cases of retinitis are often regarded as weakness of sight, characterised by a morbid sensibility to light, and slight obscurity of vision, followed, after some time, by a gradual contraction of the pupil, immobility of the iris, and amaurosis.

Gentlemen, the treatment of acute retinitis consists in keeping the eyes perfectly at rest, with the benefit of darkness, abstinence, and active depletion, followed by the quick introduction of mercury into the system, belladonna being also applied, as in iritis. The treatment, indeed, is essentially the same in both cases.

Having now, gentlemen, given an account of the principal inflammations of the eye, I proceed to notice some other affections, a part of which may be regarded as consequences of inflammatory processes in the eye.

And first, gentlemen, I invite your attention to *glaucoma*, so called from the greenish colour reflected from the pupil, the iris becoming of a dull leaden or dirty green colour, the pupil dilated, the eye painful, its vessels distended, and vision generally destroyed. In the commencement of glaucoma, the green reflection seems as if it came from the very bottom of the eye; as the disease advances, the apparent opacity, which is always of a greenish colour, and often sea-green, looks as if it were situated in the centre of the vitreous humour, and at last appears to be immediately behind the lens. The opacity and green reflection are not the result of any change in the crystalline lens, but are more deeply seated. You cannot see the change by looking at the eye sideways, but only by looking towards the bottom of the eye.

Scarpa ascribes the glaucomatous state of the eye to inflammation and thickening of the retina; Professor Beer to similar alterations of the vitreous humour; and other surgeons to morbid changes in both these textures. Mr. M'Kenzie, of Glasgow, had the rare opportunity of dissecting some glaucomatous eyes. He found the choroid coat, and especially the portion of it in contact with the retina, of a light-brown colour, without any appearance of pigmentum nigrum. The vitreous humour was in a fluid state, perfectly colourless, or slightly yellow, without any trace of hyaloid membrane. The lens was of a yellow or amber colour, firm and transparent. In the retina, no trace of the foramen centrale and limbus luteus was distinguishable. No other change was noticed in the retina; for it was not thickened, nor changed in colour; neither was the vitreous humour thickened, or opaque, but perfectly fluid and transparent.

Glaucoma is always attended with a limited and sluggish motion of the pupil and other amaurotic symptoms. Ultimately, indeed, the pupil is greatly dilated, and the retina becomes insensible to light. The loss of sight, however, is generally gradual, and the want of pigmentum nigrum has been suspected to be capable of affording some explanation of the weakness of sight which accompanies glaucoma in the early stages. This, however, may not seem satisfactory to every pathologist, nor are we sure that a deficiency of pigmentum nigrum is an essential occurrence in every glaucoma.

Inflammation, leading to a destruction of the hyaloid membrane, may perhaps be set down as the proximate cause of glaucoma. The disease is much more common in old than young subjects, and is occasionally believed to occur chiefly in consequence of slow inflammation of the interior textures of the eye in gouty constitutions.

Be sure, gentlemen, not to mistake glaucoma for cataract, and the colour of the eye is sufficient to prove that, at all events, the case is not one of simple lenticular cataract.

for opacity of the lens alone is never green. Also when you dilate the pupil with belladonna, the green appearance seems to be further behind the pupil, and uniform, not streaked or spotted like a cataract.

When glaucoma has commenced in one eye, you will generally find it take place also in the other, the disease being often seen in different stages in the two eyes.

One fact is certain, gentlemen, that complete glaucoma may be set down as absolutely incurable, though it is possible that, in the early stage of the disorder, its progress may be arrested, and even vision improved. I should say, however, that the prognosis is always peculiarly unfavourable. Mild antiphlogistic treatment, with calomel and opium, may be tried, but the prospect of benefit is very slight indeed.

Instead of mercury Mr. McKenzie, of Glasgow, suggests the trial of carbonate of iron and sulphate of quinine, directly after depletion, but I know of no fact in support of the practice. Dilatation of the pupil with the aqueous solution of belladonna is sometimes found temporarily to improve the sight.

An *onyx*, or *abscess of the cornea*, gentlemen, signifies a collection of matter between its lamellæ, and so called from its being of a semi-lunar shape, like the white mark at the root of one of the finger-nails. It is generally situated at the lower edge of the cornea, and even when more extensive, may be readily distinguished from a collection of matter in the anterior chamber, called *hypopium*, by its form and situation remaining unchanged, whatever may be the position of the patient's head.

The treatment consists chiefly in the employment of remedies called for by the kind of ophthalmia, of which the onyx is an effect. As a general rule, it is the best practice not to open any collections of matter in the texture of the cornea, as you thus increase rather than lessen the risk of opacity of that membrane, and prolapsus of the iris. When, however, the onyx has a tendency to spread over the whole cornea, without bursting, it becomes necessary to make an opening with a cataract knife.

Gentlemen, you will often hear of *hypopium*, which is a collection of matter in the chambers of the aqueous humour, and frequently the anterior one. The matter is always first noticed at the bottom of that chamber, and it may increase gradually, till it not only covers the pupil but fills the chamber, and even the pupil. Sometimes it shifts its position with every motion of the head; and, in other examples, its thick glutinous properties fix it in one place. If the case be neglected, the prominence of the cornea increases, and, at last, after most agonising pain, that membrane gives way; the suffering now ceases, and the iris falls forwards, protrudes, and becomes adherent to the cornea.

In the treatment, the principal indication is to lessen the inflammation, from which the hypopium has originated, whether of the cornea or the iris; for, if you succeed in doing this promptly, and then give mercury, absorption will often proceed so quickly in the anterior chamber, that the matter will soon be removed. The best general rule is to abstain from making an opening; for, in fact, the matter is a viscid kind of lymph, which will not flow out if a puncture be made.

If the eyeball were to suppurate extensively, things would be different, and then an opening for the discharge of the abscess would unquestionably be required.

Ulcers of the Cornea are frequently the consequence of the rupture of an onyx or small abscess. In purulent ophthalmia, however, the ulceration generally begins externally, and penetrates more and more deeply, until it reaches into the anterior chamber. Sometimes ulcers of the cornea are produced by the irritation of extraneous substances on the eye, as quicklime, or pieces of glass. The ulcer is of a pale ash colour; its edges high and irregular; its margin surrounded by a slight halo of lymph, or a cloudy appearance of the cornea; it gives acute pain, discharges a thin lymph, and is disposed to spread. To the deposition of lymph around the sore, you may observe a fasciculus of vessels proceeding from the sclerotic conjunctiva; a fact beautifully illustrated in this engraving, coloured by Beer himself.

When the ulceration extends superficially, the opacity of the cornea may be destroyed; and when it penetrates the anterior chamber, the aqueous tumour escapes, and a prolapsus of the iris takes place. If the opening be large, even the vitreous humour and lens may be discharged, and the eye be destroyed. Then, if less mischief occur, the cicatrix frequently produces indelible opacity of the cornea, and more or less injury of vision.

Treatment.—Your first endeavour should be to stop the ulcerative process by means calculated to lessen the inflammation which is the cause of it. Local bleeding, therefore, is proper, as long as there is an appearance of active inflammation, and much pain is felt in the eye. The bowels are to be kept open, and opium administered. In strumous cases, give the sulphate of quinine, and wash the eye with a collyrium containing iodine, according to the formula of Lugol. In the chronic superficial ulcer, prescribe calomel. In almost all cases counter-irritation is useful. When the ulcer is kept from healing by the irritation of the motion of the eyelids, and it protracts the inflamed state of the eye, lunar caustic is the grand means of relief.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833-34.

LECTURE XIX.

Case of Gastritis with Delirium Tremens—Intestinal Worms—Organisation and Origin—Opinions of Linnaeus, Müller, and Bremaer—Occurrence of Worms in parenchymatous Parts—Existence in the Fœtus of Man and Animals—Internal formation—Pathological State of the Digestive Tube—Question of their perforative Powers—Worms in Abdominal Abscesses.

GENTLEMEN,—You may recollect that, when treating of acute gastritis, I alluded to the great importance of being aware of its complication with delirium tremens; and stated, that in the form of delirium tremens, which is the result of an excessive debauch, and where the stomach has been subjected to powerful stimulation, we have reason to believe that there is more or less of gastric inflammation. I have it in my power, to-day, to exhibit to you a very accurate drawing of the stomach of a patient who laboured under this form of disease, and whom I had an opportunity of examining several times before death. You will remember, also, I mentioned that in cases where symptoms of delirium tremens had arisen from excess, and not from a want of the customary stimulus, the ordinary routine treatment of giving wine, brandy, and other spirits, was extremely improper, and that where it was persevered in, and the patient died, you commonly found, on dissection, evident marks of inflammation in the brain and stomach. On that occasion, too, I quoted this as an example of the latency of gastric symptoms when complicated with an affection of the nervous centre. I have now to exhibit this drawing, which represents the stomach of a man who died of delirium tremens supervening on a severe debauch. This patient was treated entirely on the stimulant plan; he got wine, porter, brandy, and opium, but their exhibition was not attended with the slightest benefit. Under their use his symptoms changed and assumed a decided cerebral character: he had hot skin, quick pulse, great thirst, and general symptoms of fever, accompanied by a comatose condition. Previously to opening the body, I gave it as my opinion that the stomach would be found to exhibit marks of inflammation. Here is an accurate drawing of the stomach, and from its appearance you will be able to judge for yourselves. (*Here Dr. Stokes exhibited the drawing to the class, representing the stomach in a state of intense vascularity.*) Observe the generally diffused dark red colour of the whole organ, and the excess of inflammation towards

its cardiac orifice. The brain, in this case, was but slightly vascular.

Gentlemen, I propose to devote this day's lecture to the consideration of an interesting subject in practical medicine—intestinal worms. There are few subjects possessing so much interest, in a physiological and pathological point of view, as this; and, in order to have correct notions, it will be necessary for you to be acquainted with the investigations of modern science on this subject. You are well aware that worms are found in most classes of animals. They occur in reptiles, fishes, birds, in the different classes of quadrupeds, and in man. In man they do not exist in such abundance, nor so frequently as they do in birds and fishes. With respect to their places of habitation, we find them, first, in cavities which have an external communication, and next, in the parenchymatous substance of organs; and we generally observe, that those which inhabit the cavities are different from those met with in parenchymatous parts. We observe, also, that the species existing in the different organs and cavities are not only different in their nature, but that there is a difference between the worms which inhabit separate portions of the same organ or cavity. In one part of a cavity or organ we find one species, in another a different, and this occurs almost invariably, as if it was regulated by a fixed law of the economy. A peculiar species of worm, occurring in man, called the *distoma hepaticum*, is never found except in the liver or gall bladder. If this animal had been introduced from without, it would certainly be detected in some part of the intestinal canal, but this is never the case. Rudolphi states, that the *Strongylus horridus* is to be met with only in the œsophagus of aquatic birds, and the *Ascaris obtusa* in the stomach of mice.

Generally speaking, worms are of three different forms—cylindrical, riband-shaped, and vesicular. Their organisation varies from the lowest scale, in which we can scarcely trace, as if were, the rudiments of an animal; beginning with the tape-worm, which presents little more than a cellulo-gelatinous mass, we ascend gradually until we arrive at a high degree of organisation, where we find well-developed muscles, a difference of sex, generative organs, and, according to some anatomists, a tolerably perfect nervous system.

Now, to remove all sources of doubt and error on this interesting subject, and to establish proper principles of treatment, let us examine into the origin of these animals. I shall confine myself to the consideration of the origin of those worms which inhabit the human intestines, as they are the only species which we have to do with as practical physicians.

You will at once perceive that worms must be derived from one of two sources; either as introduced from without, or formed originally within the bodies of man and other animals. It is maintained by those who are in favour of the first supposition, namely, that they are

introduced from without, that similar animals are to be found in the external world, and that they are introduced either in the form of ova, or in a state of perfect development, with the food or drink, or by the respiration of the animal. Observe, this doctrine is founded on the validity of the assertion as to whether animals similar to intestinal worms are to be met with in external nature. Linnæus states, that he found the tape-worm, and the small ascarides, a species now called *oxyuris vermicularis*, in a marsh in Lapland: but Müller, a much more accurate helminthologist, has since shown, most satisfactorily, that Linnæus was completely mistaken, and that those he had observed are never found to exist within any animal whatever. There are many observations on record similar to those of Linnæus: but as they were made at a time when Natural History was in its infancy, and as they have been disproved by the researches of modern zoologists, I shall not notice them. I believe there is no well-authenticated instance on record of tape-worms, lumbrici, or ascarides being found living in any situation external to the animal body. Every one of you, gentlemen, have seen worms in the intestinal canal, or recently discharged by stool or vomiting, but I will venture to say that not one has ever observed them in any article of food, in earth, or in water. Bremser, who is a high authority, makes a very pertinent remark on this subject. "We find," says he, "all animals most abundant in that situation which has been assigned to them by nature. Now if these animals were accidentally introduced from without, we ought to find them more abundant in the earth, water, &c.; but the contrary we have seen to be the fact."

But it is contended that these animals may have been introduced from without, and that in consequence of a change in situation, nutriment, and other circumstances, their forms may be altered; and it is argued in support of this hypothesis that external circumstances will and have been observed to change the forms of plants and animals in a very remarkable degree. In addition to this it may be said that an alteration in the nature of its food may even produce an actual change in the function of the animal. It is a singular fact that neuter bees may be made prolific by changing their food; it is shown that when a queen bee dies or is lost, the neuter bees take a grub of their own species in place of her, and by feeding it in a particular manner, it becomes capable of laying eggs.

Now supposing that intestinal worms are introduced in the form of ova into the human body, there is no reason why this sudden, remarkable, and complete change should take place. We see nothing similar to it in nature. The plant which springs from any particular seed will resemble that from which it derives its origin; the egg of any particular bird, no matter in what way it may be hatched, will produce an organised being similar to its parent.

The form and character of the animal are given during the act of generation, and remain unchanged. Again, admitting that a difference in circumstances and nutrition might produce a total change in form, it should be in our power to demonstrate the individual in the process of transition; we should find those animals in a state half between what they were and what they are, and this state we should observe of very frequent occurrence. No such thing however has been ever demonstrated. Out of a vast number, Bremser did not find a single one in any stage of transition, nor has it been demonstrated by any zoologist. He also states expressly, that after having diligently examined 15,000 specimens of worms in the cabinet at Vienna, he never was for one moment at a loss to say which were intestinal worms and which were not. If there was any such transition it would have been discovered, but no such thing has ever been observed.

It appears then obvious that there is no direct evidence to prove that these animals have been introduced into the body from without, either in the form of ova or in a state of perfect development. We have nothing then, I think, but to come to the other conclusion, that they originate within the body, and this seems to be the opinion of the best physiologists and pathologists. This doctrine appears to be almost brought to a demonstration by the following facts. First, it appears that the worms which have been found in man and animals have a peculiar structure and organisation, differing materially from that of the worms which inhabit the external world. This is a point admitted by almost every modern writer on natural history. In the next place we find that the worms of certain animals present peculiarities differing from those of the same species in others. Thus the bothrioccephalus and taenia solium in man differ from those of other animals. You are not, however, to conclude from this that every animal has its peculiar worms, for such is not the case. Thus the lumbricus and small ascarides of man are found to exist in various animals, both carnivorous and graminivorous.

It appears obvious, that if worms were introduced from without, we should not find peculiar worms in the bodies of certain animals, yet taking a certain number of different animals living on the same food and in the same situation, we find a difference in the nature of the worms which are met with in the bodies of each. Another important fact is, that worms are to be found not only in the intestinal canal but in almost every part of the body. We find them in the cellular tissue, in the liver, gall-bladder, lungs and trachea; in the brain, heart, kidneys, and spleen. They have been met with in the air-bladders of fishes; and Treutter states that he has found the polystoma pingucicola in the ovaries of a woman which were steatomatous, and the strongylus in an aneurism of the mesenteric

artery of the horse. These animals have been observed in the anterior chamber of the eye in birds and horses, and there are innumerable examples of their occurrence in situations equally strange and anomalous. Another circumstance already mentioned, and which must be coupled with the fact just alluded to, is that there are certain species of worms which occur only in the same organs, and are never met with in any other situation.

Now observe the importance of these facts—we find that worms not only exist in the digestive tube and parts having an external communication, but also in the very substance of deep-seated viscera, and that the worms which are found in the various cavities and organs are peculiar to them. In one case we find a worm in the digestive tube, in another in the brain, in a third in the liver, in a fourth in the pulmonary apparatus, but no one has ever been able to demonstrate the trajet of a worm from one of these cavities or organs to another. It would be ideal and absurd to say in the case of worms found in the substance of viscera, that they had been introduced from without, or came from the intestinal canal. The *distoma hepaticus*, which is found in the liver and gall-bladder, might be supposed to arrive at those situations by passing along the ductus communis choledochus, but in the various cases in which it has been found, it has never been detected in the intestinal canal, and this, I think, would not have been the case if the digestive tube had been its original situation. One of the most important facts which have been stated is, that certain forms of these animals are found invariably in certain situations, and this has been observed not only in man and other animals of the class mammalia, but also in reptiles and fishes. In man we generally find the *lumbricus* inhabiting the stomach and small intestine, the *tricocephalus* in the cæcum, and the small *oxyuris*, or thread-worm, in the rectum. The preparation before me exhibits a specimen of the rarest form of worms which inhabit the intestinal canal, the *tricocephalus*. Here is the cæcum filled with these singular worms. The males are distinguished from the females by the whirl of the tail. If these little animals or the *oxyuris* had been introduced from without, we should expect to find them in various parts of the intestinal canal, but we find, on the contrary, that their situation is separate and distinct.

Lastly, *intestinal worms have been found in the fœtus, both of man and other animals*. Kerking describes a fœtus, the intestinal canal of which contained a vast quantity of small worms, and another of six months, in whose stomach a large *lumbricus* was found. Rudolphi, Blumenbach, and others of nearly equal authority, have recorded abundance of examples of worms existing in the fœtuses of various quadrupeds, and also in those of birds which had just broken the shell. Those who are obstinately attached to the doctrine that worms are introduced from with-

out, have gone so far as to assert, that the ova of the worms have been transmitted at the moment of generation, a doctrine so absurd that it is unnecessary for me to enter into any refutation of it.

With respect, then, to the formation of worms in animals, we cannot help coming to the conclusion that they are originally formed within the body, and that, in fact, there is an original generation of these animals, the result of one organisation taking place within another,—the production, in fact, of a distinct being. This idea does not appear so difficult of conception when you recollect that circumstances analogous to it are extremely familiar and of almost constant occurrence. There is not much more difficulty in conceiving the formation of a living worm within the body, than there is of conceiving the organisation of a portion of lymph thrown out upon the surface of a serous membrane. What occurs in both cases is, that under the influence of the vital principle of the original animal, a portion of matter, previously inorganic, assumes the properties of life, presents distinct traces of organisation, vascularity, and sensibility. The only difference between them is, that in one case the organised mass remains adherent to the matrix, and in the other it is cast off, and forms a separate being. In the present state of our knowledge all speculation on the mechanism of the formation of worms must of necessity be nothing more than mere hypothesis. The idea which Bremser entertains on this subject is, that *intestinal worms* are formed by the presence of semi-assimilated nutritious matter in the digestive tube. Food taken into the system under ordinary circumstances is converted into a substance fitted for the purposes of absorption and nutrition, but when the process is not perfected, it is not taken up by the absorbents, and is then, according to Bremser, converted into an animal substance. This appears to be but a crude idea, unsupported by any facts; and it would be more philosophical to say that we know nothing about the matter. Besides, worms occur in various parts of the body as well as the digestive tube; and to suppose the presence of unassimilated matter in such situations would be only supposing an absurdity. Bremser brings forward, in support of his theory, that worms are of very frequent occurrence in cases where the assimilating powers are weak or deranged, and says that nothing is more common than to meet with an abundance of these animals in scrofulous persons, in those who have great appetites and bad digestion, and in children labouring under disease of the mesenteric glands. On the other hand, there are abundant instances of worms existing without the slightest apparent injury to the general health. In certain countries almost all the inhabitants have worms. But I believe all that we can affirm on this subject is this,—that they are not introduced from without, and that they are

formed within the body by a process the nature of which is exceedingly obscure.

Now, to come to the pathology of this subject,—can we connect the formation of intestinal worms with any known pathological condition of the intestinal canal? This is a question of no ordinary importance, for if we were able to connect their formation with an inflammatory or any other state of the digestive tube, it would furnish us with a key to correct and successful treatment. The school of Broussais are of opinion that worms are the result of an acute or chronic inflammation of the gastro-intestinal surface. This doctrine is by no means supported by the evidence of facts, for it has been established *that worms are found to exist not only in connexion with every possible pathological condition of the intestinal canal, but also where the tube presented the appearance of perfect health.* We cannot, then, safely affirm that intestinal worms are connected with an inflammatory or non-inflammatory condition of the digestive tube. Andral states that he has found them in all conditions of the intestine, whether red or pale, dry, or covered with mucus. They are most commonly, he says, enveloped in a quantity of mucus, and there is some redness in the place where they are lodged, but this appears to be rather the effect of their presence than the cause. I believe it to be the fact, that persons in excellent health, and with the intestinal canal in the normal state, may have worms. Dogs who are killed while in a state of apparently perfect health, are often found to have a large quantity of tape-worm in their intestines. It is idle and hypothetic to say, that the formation of worms depends upon an inflammatory or non-inflammatory, an asthenic or sthenic condition of the digestive tube; their formation is owing to some modification of the vital power, the nature of which is unknown. I again repeat, that nothing can be stronger against the supposition that worms depend upon inflammation, than the fact of their being observed in considerable quantities in healthy individuals.

A very curious point connected with this subject is the question of perforation of the intestines by worms. This question, which is an interesting one in many points of view, has been lately the subject of medico-legal discussion, and therefore demands a share of our attention. Of the different kinds of intestinal worms, the only one which is supposed to be capable of perforating the coats of the digestive tube, and escaping into the peritonæum or some adjoining organ, is the lumbricus, which is remarkable for its vigour and for the sharp and pointed shape of its head and tail. Many of the most eminent pathologists of modern times, and among the rest Andral, Rudolphi, and Carswell, are of opinion that these worms are totally incapable of perforating the intestinal tunics. Andral states, that there is no well-authenticated instance of this oc-

currence on record; and Rudolphi declares that they have no apparatus for effecting a passage through any continuous tissue. On the other side of the question, however, there are some curious facts and cases given, which, supposing that worms are incapable of perforating, are very difficult to explain. Dr. Fischer, of Vienna, gives the case of a female, in whom the following circumstances were observed on dissection. Two circular orifices were found in the colon, communicating with the cavity of the peritonæum: in one of these openings a worm was discovered, one-half of which lay in the peritoneal sac, the other in the intestine. No other worms were found in the digestive tube, but a second worm like the former was found in the peritonæum. Here we have a very remarkable coincidence of perforation of a portion of the gut, with the existence of one worm in the cavity of the peritonæum, and another of a similar description, as it would appear, in the act of making its way in the same direction. These circumstances, together with the existence of a double perforation, seem to be in favour of the idea, that the openings had been made by the corresponding worms. Another case is mentioned in the Elements of Pathological Anatomy, by Andral, and he quotes the case, not as one of perforation merely, but to show that the symptoms of effusion of matter into the peritonæum may, under certain circumstances, be nearly latent. The subject of this case, a young man, labouring under phthisis, had a tumour near the umbilicus, which increased rapidly in size, and presented a distinct fluctuation. Soon afterwards the integuments gave way, and a large quantity of matter was discharged together with a lumbricus. During the progress of this disease there was some tympanitis, but little or no pain had been complained of. On dissection there was a considerable number of worms and a quantity of matter found in the peritonæum, and a perforation in the arch of the colon, corresponding with the extravasated matter. Bremser gives a very curious instance of this kind as occurring in a species of fish. In this case the fish died, and it would appear, says Bremser, that the worm, finding some extraordinary change had taken place, was determined to take a peep and see what was the matter, for it had perforated not only the intestinal tube, but actually made a passage for itself through the whole body of the fish until it reached the water in which it had been lying. Here, finding that its world extended no further, it stopped, and began to make its way back again to its original situation by a new opening, so that when it was observed by Bremser, the two ends were in the intestinal tube of the fish, and the middle portion external. This, however, does not resolve the question, as to whether lumbrici are capable of perforating the intestinal canal or not. My own impression on the subject is, that we have not as yet any distinct and unquestionable

evidence of these worms being possessed of any perforating power; but it is a fact, that there are a great many cases on record of worms being discharged in considerable quantities from openings in the intestinal tube, and where it would appear that the openings had been formed, not so much by the action of the worms themselves as in consequence of their exciting an irritation in some portion of the intestine, followed by inflammation, ulceration, and escape of the contents of the tube into the peritoneum. There are many instances of this kind. An interesting case is mentioned of a female, who was attacked with pain in the groin, followed by the appearance of a tumour, which she was directed to poultice by her medical attendant. After some time the integuments gave way, a quantity of matter was discharged, followed by a large lumbricus, and during the progress of the case, about one hundred of these animals were discharged through the opening. This is a well-authenticated case. Another case is mentioned of a patient who had been subject to constipation and violent attacks of colic. A tumour began to appear in the right hypochondrium, followed by pointing and ulceration of the integuments and a discharge of matter. A number of worms (I believe twenty-four) were discharged through the opening, which remained pervious, and the patient lived for many years afterwards with an artificial anus. This case appears to be not an example of direct perforation from worms, but of the accumulation of a mass of these animals in a particular portion of the intestine, giving rise to irritation, which terminates in ulcerative absorption of its tunics and escape of its contents. Inflammation is set up in some part of the intestine, this goes on until the coats are all destroyed, and the matter and worms escape into the peritoneal cavity; but if adhesion should prevent this, an opening will be formed in some part of the integuments covering the belly. In both cases the opening is produced, not by an exertion of the worms but by an ulcerative and vital process. In support of this view it has been observed, that worms have come out through these apertures not head foremost; the centre portion appears first, and you can draw it out like a loop. Such cases as the foregoing, then, cannot be fairly given as cases of perforation from worms, but as cases in which these animals, acting somewhat like foreign bodies, produced irritation, inflammation, and ulcerative absorption. There is a very curious case on record, of a patient labouring under abscess of the liver, which burst externally, and a lumbricus was discharged with the matter. The patient died; and on dissection it was found that the cavity of the abscess had a communication with the stomach, through which it was conceived that the lumbricus had got into the liver.

The worms which inhabit the intestinal canal in man are the following:—first, the lumbricus, or common round worm; next, we

have the tape-worm, of which two varieties have been described; thirdly, we have the very curious worm, of which there is a specimen before me,—it inhabits the cæcum, and is called tricocephalus; lastly, we have the thread-worm, to which the name of oxyuris vermicularis has been lately given. The lumbricus generally inhabits some portion of the small intestine, but is also frequently found in the stomach. Persons have often vomited them, and they have been known to have crept out by the mouth. They have been found also in the pharynx, œsophagus, and large intestine. There is an interesting case mentioned by Andral of a child, who, in a state of apparently good health, was suddenly seized with symptoms of suffocation, and died. On dissection it was found that a large lumbricus, which had come up from the stomach, had, when it arrived at the glottis, turned into its orifice, and, by irritating the larynx, produced spasmodic closure of that organ, and suffocation.

The lumbricus presents very marked appearances of an advanced state of development. The male has a peculiarly formed penis, the female has her generative organs well developed, and both have an extensive alimentary canal. The tricocephalus is about an inch in length, terminating in a point; the sexes are different, and the male is distinguished from the female by the circular whirl of his tail,—it is always found in the cæcum. The small thread-worms, with which you are all acquainted, are almost exclusively found in the rectum. These worms are found in vast numbers in some children; and it is said that the quantities of them which are discharged by the West Indian negroes are extraordinary.

The tenia, or tape-worm, is generally found in the small intestine; but it has also been observed in the stomach, colon and rectum. The length to which this animal sometimes attains is almost incredible. Bremser mentions a case in which a tape-worm 150 feet in length was discharged by stool. Another case is given, in which the tenia had the enormous length of 300 feet. I have myself seen a large wash-hand basin filled by a mass of tape-worm, discharged after a strong dose of castor-oil and turpentine. Still more extraordinary instances are recorded. Thus, in the Copenhagen Transactions, we read of a tape-worm eight hundred ells in length. But in all probability there has been an error in these measurements, and many worms have been taken for one. This is rendered probable by the fact observed by Robinus, who found in the body of a man, who had before death discharged fragments of tape-worm, a tape-worm extending from the pylorus to within six inches of the anus. The length of this single worm was scarcely thirty feet. One interesting circumstance connected with this animal is, that it is inferior in its organisation to every other species of worm. It

appears to be nearly a simple, homogeneous, cellulo-gelatinous mass, without any division of sexes, and without a nervous system, or generative organs. It is said also to occur principally in persons whose powers of life are low; and if this be the case, as I believe it is in many instances, it furnishes us with a very curious and interesting fact. The other better developed kinds are found in persons of healthy, good constitutions; but the tape-worms, though sometimes met with in such persons, are generally found to occur in persons of low and weak diathesis. Here we see a curious connexion between the product and the producing cause.

With respect to the exciting causes of worms, a vast number of circumstances have been mentioned by authors as giving rise to their formation. Foul air, low, damp situations, bad diet, the constant use of milk, cheese, sugar, vegetables, have been reckoned among their exciting causes. I believe we are not well acquainted with these causes. They appear often to be connected with some morbid influence produced upon the system by bad diet, and other circumstances; but what the nature of this influence is we know not.

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c. &c.

At the Westminster Hospital.

LECTURE XIV.

On the Division of Strictures.

GENTLEMEN,—The question of dividing or of not dividing the stricture after the urethra has been opened behind it, is advocated both ways by many very able men. The fact of the stricture becoming much more manageable after the irritation caused by the pressure of the bladder has been removed, has induced many to trust to the ordinary treatment in order to effect a cure; and as in cases where the bladder was punctured through the rectum or above the pubes, no other method could be adopted, and yet the canal was ultimately rendered permeable, it must be admitted that this mode of proceeding is a good one in many cases. I should say that it is, like many others in surgery, a question of degree; that this method may be adopted in all cases where the stricture is of no great extent, but that it should be divided in completing the operation in all cases in which it is of a thickness, hardness, or extent, leading to the expectation of the cure being difficult or prolonged: for it must be borne in mind, that the incision in the perinæum soon closes up, so as to become a very small opening, no better, indeed, than a fistulous one if the passage is not cleared; and

that any particular delay in effecting this object, will bring the parts into the state they are in when a fistula in perinæo has taken place from other causes, and which alone often requires another operation of nearly a similar nature for its cure. The patient also, in submitting to an operation, expects that the obstruction from which he has suffered so much should be divided; and unless it can be proved that some particular advantage will result to him from not doing it, or not having done it, he will not be satisfied with his treatment nor his surgeon if he has to undergo another, from whatever cause it may arise.

If the stricture has not been divided, a catheter is never passed from the perinæum into the bladder; but if the stricture has been divided, it is usual to introduce a catheter immediately into the bladder, which is sometimes good and sometimes bad practice. When there is but little irritation in the bladder the catheter will do little mischief, but when there has been low inflammation of its mucous membrane existing for some time, which is generally the case, the presence of the instrument gives rise to the greatest suffering, and to so much constitutional derangement as often to lead to the destruction of the patient. In no case can it do good as far as the bladder is concerned, and in many it will inevitably do mischief, and more particularly if a silver one be selected instead of an elastic gum catheter, for the end of it necessarily rubs against the upper surface of the irritable membrane and increases the evil, whilst it otherwise does no kind of good.

The particular advantages expected from the introduction of a catheter, are those of keeping the whole passage open, and of allowing the wound to heal over it, so as to re-establish the canal; advantages which I by no means undervalue, but which I well know may be attempted to be gained at too great a risk. The rule is, in my opinion, therefore peremptory, that a catheter of any kind is not to be introduced in such cases where the mucous membrane of the bladder is very irritable, or if introduced, is to be withdrawn as soon as it is found to give rise to an increase or even a continuance of irritation. As soon as the incision into the urethra is completed, the urine will flow through it, and will continue to do so for several days, without the opening being so closed up that it cannot readily be seen when the urine is discharging through it. During the period of this discharge an elastic bougie may, if necessary, be introduced for the space of an inch or two, and retained there by an appropriate bandage, as it will not prevent the urine flowing by the side of it; or a gum catheter or bougie may now be carried along the passage until it reaches the divided part. It is then to be passed into the posterior portion of the urethra, beyond the incision, but not into the bladder; and if it is not carried into the bladder it will not give rise to irritation.

None but those who suffer can know the relief which is obtained by withdrawing a catheter one inch from an irritable bladder, and no precise directions can be given on this point in survey. It must depend on the feelings and sensibility of the patient. I have seen a man with an irritable bladder draw out the catheter and throw it away in despair, although he knew he should not be able to pass his water an hour afterwards. The present agony overcomes all feeling for the future, until that future in turn becomes the present. The relief obtained by allowing the instrument to remain in the urethra instead of the bladder is often great, and it answers every purpose just as well, and can be advanced at any time if necessary. The mechanism required to retain a catheter or bougie at a given distance is simple. The catheter should rarely exceed eight inches in length, and may sometimes be shorter, as it never should project half an inch more than is necessary. It should have a silver extremity to which two rings are affixed, and to each of which a piece of strong bobbin, ten inches long, is to be attached. The catheter being introduced to the proper distance, the two pieces of bobbin or strong thread are to be carried backward along the sides of the penis as far as the pubes, and a fine slip of sticking plaster is then to be bound round the middle of the penis and over them, so as to fix them firmly to it, and which the sticking plaster does as well as anything else. The ends of the bobbin or thread are then to be turned forwards on the outside of the plaster, when they may be tied together on the end of the catheter, which is thus steadily fixed in its place, subject, however, to any motion of the part generally, with which it moves as a whole, and the patient soon learns to manage the matter for himself, so as to change it whenever he pleases without inconvenience; or an elastic band may be sewed or buckled around the penis, with hooks attached to it, through which the threads may run.

There are still two advantages supposed to be obtained by dividing the stricture from without, and by introducing the catheter through the part, and which may be gained by this mode of proceeding. The one is, that the presence of the catheter causes the absorption, and of course the removal, of much of the diseased urethra; and that the division of the outer wall of the urethra renders it less liable to a return of the disease than if the cure had been accomplished by any other means. The first point I admit: the second is doubtful; for I may say I have as much evidence one way as the other. In the course of the last thirty years I have had many opportunities of dividing, and more of seeing the urethra divided by others, for the relief or cure of persons labouring under strictures. In most of these cases the disease has returned in the course of a few months, or would have returned if the patients had not made use of the

solid sound regularly every five or six days to prevent it. In the year 1816 I saw the late Mr. Pearson divide a stricture at the part where the scrotum begins, for the extent of an inch, or as much as was hard and gritty; the patient got quite well, and could pass a large bougie with ease; but he subsequently neglected himself, thinking it unnecessary, and one year afterwards I saw him just as bad as he had been before. I find in my case-book two admirable instances of this disease, and of this mode of treatment, and in both the complaint would have returned if not prevented by the use of the bougie. They were under the care of my colleague, Mr. White, in the Westminster Hospital, and I assisted him in the different steps of the very difficult operations they required. In both instances the disease returned, and the necessity for the occasional use of the bougie was demonstrated in the strongest manner.

A friend of mine (now no more), the late Dr. O'Halloran, of the 60th regiment, suffered for many years from stricture; and fifteen years ago took particular interest in the improvements I was attempting to make in the solid instruments, so as to cause them to dilate when introduced into the urethra, and was one of the first on whom they were used. They did him no good; and from neglect of the common sound his stricture contracted, so that he suffered great inconvenience from it, and being in the West Indies, was rendered almost incapable of duty. Being a man of great resolution, he determined on dividing it from the outside, and placing himself before a glass he cut away in the perineum, just behind the scrotum, until he had completely divided it. He assured me, three years afterwards, that the cure was complete, and that he had never since had occasion to pass an instrument.

The division of strictures by an instrument passed along the canal and down to them, has been often tried and as often abandoned, until of late, when the practice has been revived by Mr. Stafford in very obstinate cases. The general surgical opinion is against it, as being exceedingly dangerous, although I do not think it merits the reprehension it has met with, and may in some cases be advantageously employed. The mode of treatment I have adopted for impassable strictures has rendered it unnecessary to have recourse to it in them, unless the case is so very urgent from retention of urine that no delay can be admitted. In such instances a surgeon may choose; if he fails in dividing the stricture from within he must do it from without. If he succeeds, he should introduce a catheter into the bladder, and allow no urine to pass along the urethra for three or four days, as I have known several severe paroxysms of ague to follow its doing so; and if any evil consequences should take place, it is still but opening the urethra from without. The ill consequences alluded to have, I think, been over-rated; and the

most that can fairly be said is, that if it does not succeed and does no good, it does no harm, and the patient is not in a worse state than he was before.

In cases of passable narrow strictures, which are very troublesome from their irritability and propensity to contract, the division of them is sometimes followed by remarkably good effects; but poor patients, even in hospitals, do not willingly submit to the operation; and many in higher life have so much dread of anything of the kind, that the practice is only likely to prevail in very severe cases.

When the surgeon is unhappily too late, and the urethra has given way by ulceration behind the stricture, the urine makes its escape into the surrounding cellular texture in the perinæum; but as this part is bounded posteriorly by the superficial fascia, which turns under the transversus perinæi muscles to join the deep fascia, the urine can only pass upwards and forwards; it distends, therefore, the scrotum, the integuments of the penis, and often extends even into the cellular structure above the pubes, and into the groins. It has been usual in these cases to scarify the parts deeply so as to allow the urine to drain off, and await the event; but this is not sufficient; a fair and free incision must be made in the perinæum, in any way the surgeon may choose, according to the nature of the case, until the superficial fascia is fully divided, and a free and direct passage for the urine is obtained, so that there may be no disposition, and indeed no possibility of its escaping into the surrounding cellular structure, on account of the dependent outlet which is made for it. The urine being the natural stimulant of the bladder, exercises none but its ordinary power on it; but when it is extravasated, and leaves the natural passages for the cellular structure surrounding them, it gives rise to unhealthy inflammation and mortification to the extent to which infiltration has taken place. In order to prevent the complete destruction of these textures, it is not sufficient that incisions be made, for instance, into the scrotum, or the surrounding integuments, with the view of facilitating its evacuation, or that it be even pressed or squeezed out, but the further admission of urine must be prevented, by making such a dependent opening as will allow it to run directly off without the least impediment. A solid sound or a catheter should be passed down the urethra to the stricture as a guide; and if it be as far down as six inches, an incision is to be made in the perinæum, on either side, as may seem preferable, and nearly as in the operation for the stone; this is to be continued inwards, until the finger can distinguish the point of the instrument in the urethra, in front of the stricture behind which is the rupture or hole in the urethra; and the parts must be so dilated that the urine will run directly on, without further infiltration.

In these cases it will always be better to divide the stricture if possible, and carry the catheter into the bladder, from whence the urine may be drawn off every two or three hours, as may seem necessary.

The destruction of parts by the urine is so rapid, that few survive an extravasation of this nature, unless the art and science of surgery are brought forth almost immediately for their relief and assistance, so that the urine may be pressed out as quickly as possible, and the entrance of any further quantity be prevented. I am aware that in such circumstances it may be said, that the patient will inevitably die, if an elderly man and of a bad constitution, in spite of all that surgery and physic can do for him, and it will in all probability be truly said. Still the fact is, that in one case he must die, in the other he may not; and an enlightened and well-educated surgeon must estimate his patient's strength and constitution, and proceed accordingly. I never recommend an unnecessary operation, but I have done operations successfully, and seen them done successfully when abler men thought they must be useless. The preparation before you is from a man advanced in life, who died in this hospital through an accident. He came in very ill with retention of urine. I passed a gum catheter, which surmounted an obstacle without much difficulty about six inches down, and drew off his water, mixed with blood, mucus, and a purulent deposit. The gum catheter gave to the finger the sensation of passing over or through a rough, grisly body, which I thought it had done, and it was fixed in the bladder. Early in the evening, however, it slipped out of the bladder, and the patient, thinking he could do without it, attempted to make his water in the natural way, and forced it into the scrotum, penis, and surrounding parts. It was not discovered by the house-surgeon until the morning, and when I arrived in the middle of the day, he was sinking so fast, that any operation would have been as cruel as it would have been useless. He died shortly afterwards, and on examination the canal of the urethra was found pervious for a good sized catheter which I had used; but a stone had passed from the bladder into it, and had embedded itself on the under part, and eventually gave rise to ulceration in it, through which the urine escaped into the cellular texture and destroyed him, already nearly worn out by long-continued irritation. The inflammation induced by the ulceration had caused the retention of urine, and if I had used a silver catheter, instead of a gum elastic one, or if it had not so readily passed into the bladder, I should have discovered the stone, and removed it by an incision at once. The great object I have in view in mentioning this case, is to show that such an extravasation is not always caused by stricture, and that the removal of the stone by an incision would have prevented the evil, inasmuch as the

urine would have escaped through it, after the catheter had slipped out of the bladder.

After the operation has been done, and the safety of the patient has been so far ensured, your attention must be turned to his general state. Saline medicines, or gentle saline aperients with opiates, will be the best remedies to soothe and allay the constitutional irritation which has taken place; a stage farther, camphor, opium, with saline draughts made with the carbonate of ammonia, will be advantageous, and if gangrene has taken place, ammonia, brandy, quinine, acids, and opium, will offer the best chance of success; but all will and must be useless if the passage of urine is not free, so that no further extravasation can take place. The incisions into the parts distended by urine should be sufficiently long and deep to allow the urine to be squeezed out of the scrotum, and to drain out where pressure cannot be applied, and if the cellular membrane has sloughed, they must extend into the slough. Poultices of stale beer and linseed meal are the best applications, followed by stimulating dressings, but the treatment will be tedious, the whole skin of the scrotum being frequently lost, and a fistulous opening remaining in the perinæum.

Erysipelas will sometimes attack the scrotum, and simulate the appearance derived from extravasation of urine. I was once called to a case of this kind, in which the scrotum was greatly distended, and I was at first sight disposed to attribute it to that cause, but the patient declared he not only could make his water well, but had never had any difficulty in doing it. I was not, however, satisfied until I had passed a catheter and assured myself that there was no disease in the urethra, nor in the perinæum. The patient recovered, but lost a good deal of the skin of the scrotum by sloughing, in spite of several incisions into it, which saved the remaining portion.

A pervious urethra is, however, no proof that an extravasation of urine may not be caused by ulceration in it, but then the extravasation does not take place quickly; the scrotum and adjacent parts are not suddenly distended; the swelling commences slowly,—is situated in the perinæum, where its progress is marked by pain and hardness. It is owing to inflammation, which has taken place outside the urethra, ending in suppuration, and the matter of which cannot find its way to the surface, in consequence of the superficial fascia, which prevents its progress. The pain is often great, the irritation greater, and there may be and often is retention of urine, although the passage is pervious for a moderate-sized elastic catheter. If a lancet is pushed into a swelling of this kind it always gives relief, although no matter should follow for a day or two; if matter should follow the relief will be great, and a little urine will be observed to trickle through a day or two afterwards. In some cases the urine starts forth with the matter to a distance on opening the abscess,

but even in this case the inflammation, which existed previously to the ulceration of the urethra, will have consolidated the cellular structure, and an abscess will be formed in the usual manner, with its proper sac retaining and preventing the flow of urine from it. This abscess is to be prevented by rest, leeches, fomentations, and the usual antiphlogistic means, without meddling with the urethra, but as soon as the formation of the matter of the abscess is certain, the sooner it is opened the better. The wound in it, as well as the ulceration in the urethra, will sometimes heal with the simplest after treatment. In other cases the external wound must be laid open and dressed from the bottom with slight stimulants, whilst a catheter must be kept in the bladder or urethra, in order to prevent the urine passing through the wound, for the encouragement of the granulation of which caustic applications, and even the actual cautery, by means of a wire heated to a white heat, have been strongly recommended. Many surgeons advise in these cases the dilatation of the urethra, beyond even its natural size. It has appeared to me, from the consideration of very many of them, that this mode of proceeding is objectionable; for, that the urethra should be dilated, where a stricture exists anterior to the ulcerated opening, is consonant with my views: if the natural size of the urethra is as 12, a No. 13 may be used until it passes easily, but a No. 11 should be had recourse to when it appears desirable to expedite the closing of the ulcerated part. I do not see, I confess, what advantage is to be gained by over distention and the separation of the ulcerated edges, whilst I think I can perceive the good which may be derived from allowing them to remain in contact. The catheter should be large enough to prevent the flow of urine by the side of it, but not so large as to distend completely the canal. The spot when healed will always be liable to re-open on the recurrence of a much less degree of irritation than that which originally gave rise to it. If a considerable portion of the urethra, anterior to the fistula, is impervious, it must be divided, the bladder at the time of the operation being as full of water as it can hold, so that the posterior, or ulcerated opening into the urethra, may be seen on the patient's discharging it, during which process a small director can be introduced, and the orifice, if necessary, enlarged, so as to admit a proper catheter. When a portion of the urethra has been lost, in a circle or nearly so, it is a very difficult thing to establish the canal, and sometimes a fistulous opening will remain even when the largest bougie can be passed with ease. Pressure on the orifice of the fistula often in these cases prevents the inconvenience which would otherwise arise from it.

ON ERYSIPELAS PHLEGMONODES,
AND AMPUTATION AT SHOULDER-
JOINT AND ACROSS THE FOOT.

BY PROFESSOR LIZARS.

ERYSIPELAS phlegmonodes was, during the last winter, very prevalent in this city. Some of the cases under my care in the Surgical Hospital of the Royal Infirmary ended in such destruction of the parts affected, as to require amputation; others defied the most active general and local treatment, and ran on to a fatal termination, without even an opportunity of having recourse to this operation.

In some patients the disease began locally, for example, in the foot and lower third of the leg, and seemed at first quite superficial, apparently extending no deeper than the subcutaneous cellular tissue; for, on making the ordinary free incisions, sero-purulent effusion flowed, and the affection appeared to be arrested; a few days, however, scarcely elapsed, when abscesses formed between the muscles, and, when the synovial sheaths of their tendons and the synovial membranes of the articulations inflamed and suppurated, so affected the limb as to demand its removal.

In others, the inflammation at the commencement, also superficial, became deeper and deeper daily, and destroyed the periosteum and synovial membranes of the joints and the tendons of the muscles; and it extended from the fingers to the shoulder, or from the toes to the hip-joint. The consequent constitutional excitement or inflammatory fever prevented every operation.

In some individuals an irritative fever was present from the beginning to the termination, as if it had been a purely idiopathic affection. In these the course of the disease was very rapid.

The local treatment consisted in incisions from two to three inches long, and as deep as the disease, and in fomentations of poppy-heads and camomile flowers, and in oatmeal or bread poultices. The general treatment consisted of calomel and aloes, of the solution of the tartrate of antimony, of acidulated drinks, effervescent draughts, low diet, and rest; and, when the activity of the disease was subdued, of animal soups, gin, and wine. By the incisions, enough of blood was lost to render unnecessary the use of the lancet. In

some cases, so many small arteries and veins were cut, that the arm or leg required to be elevated considerably above the level of the body, in order to stem the bleeding; this seldom failed; when it did, the wounds were stuffed with dry lint. The elevating of the extremity throughout the cure is of vast importance, as it diminishes the quantity and momentum of arterial blood in the vessels affected, and facilitates the return of the venous.

The rubescence was, in some instances, so very trifling, that the only indication of pus was an oedematous or boggy feel; the appearance was rather that of phlegmasia dolens than of erysipelas.

In two of the amputations I varied the manner of performing the operation as follows:—In that across the foot, between the tarsal and metatarsal bones, I made a large flap from the sole of the foot, which extended from the commissures of the toes to the bases of the metatarsal bones. I began at the os cuboides, or the tarsal extremity of the metatarsal bone of the little toe, and continued along the outer margin of the foot to the commissures, thence round to the inner margin of the foot, and then backwards to the tarsal extremity of the great toe, or to the os naviculare. This semi-lunar or horse-shoe shaped flap was then dissected from the metatarsal bones, in order to make it as fleshy as possible. I next made an incision through the integuments and tendons on the upper or patellar aspect of the foot, of a semi-elliptical shape, the convexity towards the toes, a little distant to the tarso-metatarsal articulations, and extending from the little to the great toe, thus forming a connexion with the flap on the sole of the foot. I then, grasping firmly with the left hand the toes to be removed, divided the insertion of the peroneus brevis, the upper tarsal and the inter-transverse ligaments, and lastly, pressing down the toes, the plantar ligaments, and the insertion of the peroneus longus. The division of the peroneus brevis should be attended to, as it enables the operator to ascertain readily the articulation between the os cuboides and the metatarsal bone of the little toe, for when this joint is opened, the others are easily done.

On the removal of the diseased part of the foot, the anterior tibial artery was secured,

and then the branches of the plantar arteries. These vessels were compressed by the fingers of an assistant during the operation; the former, as it runs along the upper aspect of the foot, and the latter where it courses around the malleolus internus. After this, the large flap from the sole of the foot was approximated to the skin on the upper aspect of the foot with small ligatures.

The other instance mentioned, where I modified the mode of operating, was amputation at the shoulder joint. The patient was placed on a table on his back, the arm being held at right angles to his body, and pronated as much as could be easily borne. I then, grasping with my left hand the integuments and muscles on the outside of the joint, made an outer flap, cutting from without inwards, the half of the deltoid and the insertions of the latissimus dorsi and teres major muscles. The insertions of the teres minor, infra-spinatus and supra-spinatus muscles, together with the capsular ligament, were next divided, the knife being held at right angles to the head of the os brachii, during which the assistant supinated the arm to remove the long head of the biceps muscle from the axillary artery, in order to divide it, and enable the surgeon to dislocate the joint. The head of the bone of the arm was now easily removed from the glenoid cavity of the scapula, and the knife carried sufficiently close to it and its neck to permit the fingers of an assistant to grasp the inner flap and axillary artery; I then completed the operation. In compressing the artery the assistant must recollect, that it runs along the lower border of the inner flap. This vessel was then secured, and also the posterior circumflex, which branch emitted blood during the operation, and required the finger of an assistant on its bleeding mouth. A branch of the supra-scapular artery required a ligature, and was troublesome from its deep and hidden situation. The man lost only two or three ounces of blood. The flaps were approximated with stitches, as in the former case, a mode of dressing preferable, in my opinion, to all others; only one or two, however, should be taken immediately after the operation, as primary hæmorrhage may supervene, the rest being deferred for eight hours. The ligatures ought to be common unbleached linen thread. As soon as the operation has been performed,

a large piece of lint dipped in cold water should be applied and kept wet for the ensuing twenty-four hours, and the stump well elevated, in order to prevent hæmorrhage. After this period the lint ought to be wetted with warm water, to prevent erysipelas following. Either of the preceding operations ought not to occupy more than thirty seconds, any more than an ordinary amputation.

In these, as in all the capital operations which I have performed in the Surgical Hospital of the Royal Infirmary, I have been ably assisted by my colleague, Mr. Liston.

Edinburgh, 38, York-place.

21st April, 1834.

**A CASE OF CONFLUENT SMALL-POX
AFTER VACCINATION — OPENING
OF THE PUSTULES.**

BY JOHN LANGLEY, ESQ., SURGEON.

ON the 21st of March I was called to attend upon a fine robust boy, 12 years of age, who was suffering from severe pains in the loins and epigastric region, coated tongue, and constipated bowels; from the tumefaction of the skin and excessive præcordial oppression I was induced to suspect some suppressed eruption, and in reply to my interrogatories was informed that he had passed through the usual infantile eruptive diseases, with the exception of variola, as an antidote to which, when 18 months old, he had been vaccinated at an appointed vaccine institution, and, upon examination, I found full evidence upon each arm of the integumental mark.* I prescribed a brisk purgative of calomel and jalap, followed with a diaphoretic saline, and had him immersed in a warm-bath; on the following day an equivocal eruption appeared, which in course of time proved to be variolous, and a profuse confluent pock was the issue. The disease progressed with alarming violence, notwithstanding active antiphlogistic treatment, until the 10th day, when the face, neck, body, and lower extremities were one mass of vesicated surface, the distinct pock bearing little comparison with the general confluence; the fever was alarmingly high; the cerebral irritation excessive, manifested by delirium; the respiratory functions greatly disturbed; and the general tumefaction of the integument presented a most formidable and loathsome aspect;

the suffering was most acutely felt and expressed, and appeared to me to be greatly heightened by the excessive tension of the skin. I forthwith determined to evacuate the contents of the vesicles, and, in furtherance of such view, with a common lancet made free incisions in the purulent flakes, and punctured all the distinct pocks within my reach, amounting to hundreds; I then, with a sponge and warm water, bathed the surface and evacuated the contents of the vesicular cysts, the parietes of which collapsed, and the comfortable and soothing application of the warm water not only cleansed but relaxed the distended surface; the ease experienced was evidently apparent: after this operation I gave seven minims of laudanum with half an ounce of oil of ricini; a tranquil night was the result, with an abatement of the febrile symptoms; no ill effect resulted from the admission of air into the emptied cells: in 24 hours the surface was covered as it were with dry scales, which in a few days desquamated, leaving the subjacent integument so unimpaired as to induce me to hope, contrary to previous expectation, very little disfigurement will ensue.

Foreign Medicine.

Remarks on the Guinea Worm. (*Gordius medinensis*.)

At a late meeting of the Académie des Sciences, M. Blainville read a letter from M. Jacobson of Copenhagen, containing some interesting and novel details on the guinea worm (*les dragonneaux*). An Arabian had been admitted into the hospital at that city for a tumour situated at the external malleolus, caused by a worm of this description, which was, after many unsuccessful attempts, at length extracted. A similar tumour having formed on the other ankle, an incision was made, and the instrument having divided longitudinally one of the worms, there escaped from the opening a purulent matter, which (examined with a microscope) showed a great number of little elongated filiform worms, with heads slightly enlarged, and tails short and much thinner than the remainder of the body. Having extracted the worm entire, M. Jacobson then saw that it presented the same

phenomena in all its parts; judging from which he was led to the conclusion, that what is called a guinea worm is not one individual worm, but a collection of them living in the same nidus.

M. Blainville thought it would be interesting to discover whether all the worms of this kind presented the same phenomena; and he proposed that M. Clot should be requested to repeat these experiments in Egypt, who often had occasion to observe these animals, and that the physicians attached to the establishment at Algiers should also be requested to take observations of them.

Transmission of Sounds through the Bones of the Cranium.

At page 18 of the present volume of the Medical and Surgical Journal are some experiments, showing that sounds may be transmitted to the brain through cicatrices in the skull, thus proving that the ear is not essentially necessary to audition. Treviranus, Esser, and others have also shown that sound may even be conveyed through the osseous walls themselves, but hitherto no person had drawn the attention of physiologists to the use of thinning of the cranium, as relates to the exact appreciation of musical notes, until M. Majon, of Genoa, presented a memoir on the subject to the Royal Academy of Paris. He was led to investigate this subject in consequence of examining the body of Dr. Bennate, the bones of whose head were found much thinner than ordinarily is the case, being even transparent in many places. A like organic peculiarity had already been observed in the cranium of another celebrated Italian musician by the same physiologist, who, reasoning from this coincidence in appearance in the head of two such great philharmonists, presumes that the cranium is not altogether passive in the perception of sounds, and that the difference in the thickness of its walls may contribute to the more or less clear appreciation of the different connexions, qualities, and harmonies of sounds, and so lead us to regard these osseous parietes as a kind of harmonic case, which communicates the vibrations to the acoustic nerve. To confirm this opinion, the author of the paper notices the fact of deaf persons clearly perceiving the sounds of a piano, or organ, when one end of a rod of iron is placed on the sinciput, whilst

the other rests on the instrument, or the ticking of a watch when it is placed on the temple.

Comparative anatomy tends rather to strengthen this opinion, for it is well known that in a great number of animals the transmission of sounds is favoured by numerous extensive sinuses and furrows in the bones. It is also probably in consequence of the thinness in the cranium and of the elastic laminae which are found in its cavities, that the very remarkable appreciation of sound in some birds is due, and perhaps the small osseous globes, which are found in a great number of animals, may contribute to their audition. May we not imagine, says M. Majon, that the thickness of the bones of the head, in advanced age, has some connexion with senile deafness? When, in the midst of a great noise, we press the head with both hands, is it not for the purpose of stopping the vibrations of the cranium, which, becoming too powerful, become annoying and even painful?—*Journal Hebdomadaire*.

The Influence of Clothing on our Organs—Deformity of the Cranium resulting from the custom of covering the Heads of Infants.

BY DR. FOVILLE, OF ROUEN.

In this work Dr. Foville states that he was led to this subject, by observing the extreme constriction which the Norman women make use of in covering their heads, partly for the purpose of smoothing the skin over the forehead, and partly to form a solid base for the gigantic edifices of dress which they carry on their heads in some of the cantons. This practice, which is pursued also in clothing infants, frequently leaves indelible traces of its injurious effects, for in the asylum for the insane at Rouen, the proportion of deformity of the cranium are 46 out of 100 in males, and 67 in females; such is the influence of this state of the cranium upon insanity, that it is in patients who are the most completely affected that the greatest instances of deformity of the cranium are found. Amongst the morbid results of circular compression, the author enumerates meningitis, cerebritis, epilepsy, imbecility, &c.

Contraction of the Fingers.

M. Sanson, in commenting on a memoir entitled "Researches on Permanent Contrac-

tions of the Fingers," by M. Goyraud, of Aix, remarked that this affection was usually referred to contractions of the flexors of the fingers, until M. Dupuytren pointed out that it was owing to contraction of the aponeurosis and its processes: this, however, cannot apply to the second phalanges, contractions of which M. Goyraud had ascertained to be caused by fibrous bands, which he believed to be of recent formation, and there were dissections showing this to be the case. His method of treatment was to make a longitudinal incision through the skin, and remove the bands, by dividing them transversely on a director: the fingers were then to be extended, &c.

Experiments and Observations on the Gastric Juice, and the Physiology of Digestion.

Mr. Beaumont, a surgeon in the United States' army, having had under his care a Canadian, who, from a gun-shot wound in the epigastrium, had a fistulous opening into the stomach, tried several experiments on digestion, from which he has arrived at the following conclusions:—1st. That animal and farinaceous substances are more easily digested than vegetable. 2nd. Digestion is facilitated by the softness and minute division of the substances. 3rdly. The action of the stomach and its fluids is the same on all kinds of food. 4thly. The digestibility of a substance does not depend on the quantity of alimentary principle contained in it. 5thly. The quantity of nourishment taken is generally too great. 6thly. The quantity of the food is as important as the nutritive quality of it. 7thly. Oily substances are difficult of digestion, though they contain a large proportion of nutritious principle. 8thly. The time necessary for digesting a meal varies according to the quantity and quality of the food; a moderate repast requires from three hours to three hours and a half. 9thly. Stimulating seasonings and spirituous liquors are injurious to a healthy stomach. 10thly. Substances introduced directly into the stomach are as quickly digested as those which pass to it by the mouth and stomach, saliva having no solvent power over food. 11thly. Gastric juice is not secreted by mucous follicles, but by particular vessels, and the secretion does not take place unless some stimulant, as food, be present; it coagulates albumen, and then dissolves the coagulum; when deficient in

quantity, indigestion ensues. 12thly. Bile is not, commonly, necessary to digestion, but when oily substances have been taken, it comes in to aid the process. 13thly. Chyme is homogeneous, but variable in colour and consistence; towards the end of chymification it becomes more acid and stimulating, and leaves the stomach more quickly. 14thly. Water, spirituous liquors, &c., are not acted on by the gastric juice, and do not remain long in the stomach. By placing the bulb of a thermometer in the stomach, Mr. B. ascertained the temperature to be $37^{\circ} 7$ (centigrade); that it is not elevated by the ingestion of aliment, and that it is lower during sleep; the temperature of the pyloric end was $0^{\circ} 4$ (cent.) higher than that of the splenic extremity.

ST. PANCRAS MEDICAL ASSOCIATION,
For promoting and carrying into effect a self-supporting Charitable and Parochial Dispensary, "by the adoption of which our philanthropy may be reduced to a system, our best class of Poor prevented from retrograding into Pauperism, and our necessitous and legitimate Paupers separated from the comparatively improvident and vicious."

PRINCIPLE AND OBJECT OF THE INSTITUTION.

1st. To place within the reach of the industrious artisan of small income the means of obtaining medical aid, without subjecting him to the necessity of seeking humiliating charity, or destroying his honest pride, by exposing him to the demoralising influence of the poor laws.

2nd. To afford gratuitous relief to persons of real desert, who may be unable to procure by their own efforts the advantages above described.

The first-mentioned or *free class* of patients, may obtain for themselves surgical and medical attendance by assuring with the small sum of sixpence per month, which is not equal to the amount frequently wasted by them on nostrums and self-prescriptions. In virtue of this premium they may demand and obtain the most efficient professional assistance and medicines, and to their demands, the number of surgeons ensures immediate attention; thus will be saved the time and labour often fruitlessly and always painfully bestowed on seeking the

signature of a governor of an honorary dispensary; the unfortunate will be spared the bitter degradation of asking charity, for which will be substituted the honourable satisfaction of claiming assistance as a right, and obtaining it immediately.

The second object of this institution will be attained by the aid of the charitable and humane, who are entreated to be discriminating in the bestowal of their kindness, and thus ensure the legitimate application of their bounty to persons whose destitution unhappily precludes them from the benefits which the industry and self-respect of the first class (the free members) procure for themselves.

As the sum which will entitle the donor to have a patient constantly under medical care, is only half the amount invariably demanded by honorary dispensaries, those who are anxious to give the most extensive effect to their humanity, will see the advantage of supporting this institution. The means by which this superiority is obtained over honorary dispensaries are the following.

The surgeons constituting this Association will dispense their own prescriptions, thus saving the cost of keeping up a dispensary house and appendages, and salary of dispensing apothecary, a charge equal to at least a third of the whole income of such institutions; in other words, of every guinea subscribed by the humane and excellent supporters of these charities, less than 14s. are appropriated to the literal benefit of the poor. This obvious advantage will enable the St. PANCRAS MEDICAL ASSOCIATION to allow subscribers of one guinea annually to have two patients constantly on the books, and subscribers of half-a-guinea, one. For proportionate increase of subscription, corresponding privileges are allowed.

Application to be made to any of the surgeons of the day from ten till twelve o'clock. The surgeon to whom application is made, will continue to attend to the case till its termination.

N.B. Any of the surgeons may be consulted till eleven o'clock on Sunday.

Extracts from the Laws and Regulations of the St. Pancras Medical Association.

18. Surgeons shall prescribe and furnish medicines at their own houses unless the

patient be too ill to go out; he shall then be visited by his surgeon at his (the patient's) own house.

19. The free members shall consist of working men, their wives and children, and of any other persons who may be unable to provide themselves with medical aid and drugs in the usual manner; the terms of subscription to be sixpence per month from each member above twelve years of age, and three-pence per month from each member under that age.

20. Persons wishing to become free members, must send, or have sent for them, their names, age, and places of abode, to any two members of the Association, who shall immediately present the same to the Treasurer, and report it to the next committee meeting; any one of the surgeons failing to do this, shall be fined one shilling, to go into the general fund.

21. No free member shall be entitled to relief unless all arrears be paid up; every free member in arrear one month shall be fined 1*d.*; if two months, 2*d.*; if three months, 3*d.*; and if a longer period, shall forfeit all benefit derivable from the Association. Each member shall, at the time of his entering as a free member, sign a paper agreeing to this law.

22. Poor married women, who are free members, may be attended in their confinement by any one of the surgeons they may please to select, on paying ten shillings as a fee, with the Treasurer, two months previous to their confinement.

23. The ten shillings so deposited, to be paid by the treasurer to the surgeon who has attended the case, at the next quarterly general meeting succeeding the attendance.

24. All free members shall belong to the Institution for at least four months before they shall be entitled to the benefits thereof; but any person may become a free member by paying four months' subscription in advance, unless they apply for admission during sickness, then they shall pay twelve months' subscription in advance.

25. Donors of ten shillings and sixpence annually, shall be entitled to have one patient always on the sick list; donors of one guinea annually, shall be entitled to have always two patients on the sick list; and for every additional half-guinea, they shall have the privilege in favour of an additional patient.

HARRISON'S SPINAL INFIRMARY.

At a Meeting held at the Gethic Hall, New Road, April 26th, 1834,

JOHN UNDERWOOD, Esq., in the Chair,

THE minutes of the meetings which had been previously held were read and confirmed, and

Dr. Epps, in moving the first resolution, stated, that he was so convinced, both of the benefits resulting from Dr. Harrison's plan of treatment, and of the fact that the plan itself is as scientific in principle as successful in practice, as to feel it his duty to give it every support; and he further added, that, as his own experience as a medical man satisfied him that many diseased states are dependent upon a mere disordered state of the spinal cord, he could readily conceive that a permanent deformity must be productive of an immense amount of suffering and of disease; how valuable, therefore, an institution for the relief of these diseased states must appear to him. He thought further, that this Infirmary would be beneficial to the profession in leading its members to see the importance of investigating and appreciating the influence of modifications of the spinal system upon the general health.

Charles Wing, Esq., Wm. Sedgwick, Esq., — Levison, Esq., and other gentlemen spoke in favour of the Institution, testifying from personal knowledge to the benefits of Dr. Harrison's plan.

Griggs Lunn, Esq., moved the thanks of the meeting to Dr. Harrison for his noble donation of one thousand pounds, and testified from a long acquaintance with that gentleman, an acquaintance founded thirty years ago, to his zeal in every thing that tended to diminish human suffering and promote human happiness.

A vote of thanks was moved by Captain Underwood to Drs. Harrison and Serny, Physicians; also to Thornber and Hoyland, Surgeons, for their offer of gratuitous medical and surgical services.

Thanks were then voted to the Chairman, who stated that he had been so fully satisfied of the excellence of Dr. Harrison's plan, by his own observations, that he had felt it an imperative duty to come forward and endeavour to spread the benefits thence arising, by aiding in establishing an Infirmary, and that from the experience which he gained in India,

where he had established a hospital for the native poor, he pointed out the necessity of setting apart all the donations as a fund, not to be appropriated to the current expenses. He thanked the meeting for their kindness in attending to aid in the establishment of an Institution in which every good man must feel interested.

After the meeting was concluded, Dr. Harrison exhibited several misshapen spines, in confirmation of his own doctrines and practice; also various casts taken from the backs of very deformed patients before the treatment began, and who had obtained complete cures by his mode of practice.

One of the skeletons represented the hump-back described by Mr. Pott. The vertebræ were all sound and healthy, which prove that this eminent surgeon had mistaken the nature of these formidable maladies. Another skeleton exhibited a striking example of the lateral curve, and was completely at variance with the principle upon which muscular or gymnastic exercises are said to be useful in such cases. The Doctor declared, in commenting upon it, that no cure had ever been performed by muscular exercise alone.

This charity will commence its work of benevolence as soon as the funds are sufficient for the purpose.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, April 19th, 1834.

DR. GREGORY in the Chair.

Torsion of Arteries successfully performed at the Northampton Infirmary—Extraction of Calculi from the Urethra—Conclusion of the Session.

MR. COSTELLO rose, and said that he had much pleasure in stating to the Society a fact which would be gratifying, and that was, that Mr. Percival, of the Northampton Hospital, had lately amputated an arm, and secured the vessels by torsion. He, Mr. C., had seen the stump about ten days after the operation, and nothing could have done better. It is right to state that Mr. Percival had only made four half twists of each artery in place of six or seven, and still the operation succeeded. It

was highly creditable to a provincial hospital to be first to try a new and valuable operation, and especially as this was successful. He hoped he had now silenced those who had opposed torsion. He was aware that it had been tried at St. Thomas's Hospital by Mr. Green, but proved unsuccessful.

Mr. Greenwood was happy to hear such gratifying information, and thought the Society much indebted to Mr. Costello on this and many other occasions for his valuable contributions to science. He, however, thought that further trials of torsion were required before the operation could be adopted in this country. He again referred to M. Velpeau's case of failure, and also to the fact that torsion was not performed at the Hôtel Dieu during the last revolution. He was happy to see Dr. Ryan present, as a mistake was made in the former report of their discussions on torsion, which was, that the operation was not known in 1830, which was not correct.

Dr. Ryan assured the Society, that the gentlemen who reported for the Medical and Surgical Journal were instructed to give faithful and impartial reports on all occasions. He was very much surprised at Mr. Greenwood's statement, because he happened to have been present at the discussion on torsion, and had the clearest recollection that Mr. Costello then stated that torsion was not known in 1830. He now appealed to Mr. C. himself, and also requested the secretary to refer to the minutes of that discussion.

Mr. Costello stated that he certainly had said so, and that the report in the Medical and Surgical Journal was quite correct. The Secretary also referred to the minutes, and the Chairman laid his finger upon the report of Mr. Costello's words.

Mr. Chinnock wished to inquire of Mr. Costello, whether there was any danger of tetanus being produced by torsion.

Mr. Costello replied, that tetanus had not as yet appeared after torsion.

Mr. Hunt then introduced his motion relative to the election of the officers of the Society, which gave rise to much discussion, in which several members took a part, but which was of a private nature.

Mr. Costello then made some observations on the extraction of calculi from the urethra by means of a new instrument which he had

invented. He described the instrument, and related an interesting case of calculus embedded for ten years under the pubis, which he removed.

Several observations followed on the prosperity of the Society, and the great value of the discussions during the present session.

The Society then adjourned until October.

MEDICAL PETITIONS.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN, — Many inquiries have lately been made to me relative to the fate of a petition to parliament entrusted to my care, praying for a thorough alteration in the mode of electing all grades of medical officers to public institutions;—that they may be chosen, from the physician down to the dresser, on account of their talent, and not by their pounds, shillings, and pence, and that loathsome system of interest-seeking, so disgraceful, yet so common, in the present day. To convince all the gentlemen interested in the above that I performed my duty, permit me to state, through the medium of your Journal, that I delivered the said petition to our worthy champion and representative, Mr. Warburton, who, on presenting it to parliament, had it referred to the Committee of Inquiry with his decided approval.

It has been lately expressed in some medical journals, that such petitions at this juncture were ill-timed; and, for aught I know, an immediate allusion might have been made to this identical petition.

As, however, differing in opinion from a journalist (whatever degree of talent he may possess) is not disagreeing with a god, I must beg to observe that I do not coincide with the belief as to the impropriety of presenting a petition at this time, regarding such a fundamental point of inquiry: this may be in consequence of my stupidity, or may not. Petitions are evidence; and it is on that account that they are officially transferred to the Committee, or, at all events, they afford just ground for inquiry: they are, therefore, when clearly and concisely expressed, of great assistance to the Committee—not an embarrassment. On these accounts they should be sent in before the inquiry, not afterwards, when they can be of little comparative use. There is no good

in those who feel their grievances making a hue and cry after the battle is fought.

The mode of electing officers forms a fundamental part of the regeneration of our institutions, because they can be made strictly responsible persons; it is therefore not a thing of mere minute detail, as insinuated lately by some; let this be properly altered, then all things will, in time, go on well; unshackled emulation will be excited amongst both practitioners and students, whether we have one, two, or more great medical colleges. I therefore consider my conduct regarding this, in every iota, justifiable, notwithstanding some late animadversions which have appeared in print.

I am, Gentlemen,

Your obedient servant,

G. D. DERMOTT.

*Theatre of Medicine, &c.,
9, Gerrard-street, Soho.*

PROGRESS OF THE PARLIAMENTARY COMMITTEE.

ON Monday, Dr. Yelloly and Dr. Frampton were examined, and the next witness was Mr. Guthrie, President of the Royal College of Surgeons. This gentleman excited the admiration of a numerous meeting of the profession by his manly straightforward evidence. He defended the whole conduct of the College, on the grounds of expediency, professional respectability, justice, and public good; and satisfactorily answered the most delicate and difficult questions put by Mr. Warburton. His evidence occupied the greater part of Monday, the whole of Tuesday, and a part of Wednesday, and then his cross examination commenced, when the policy of the College was energetically assailed, and contrasted with that of Dublin and Edinburgh. The tenor of the questions was against all monopoly, and for opening the College. Mr. Guthrie admitted that some changes were necessary, but said that these could not be made until the College had legal authority. Every one admitted that Mr. Guthrie was decidedly the best witness, and the best advocate for the College that could be selected; and all felt astonished and delighted at the consummate knowledge of Mr. Warburton of medical abuses. His name will pass down to posterity as the friend of medical science and humanity. We entertain

the conviction, that the labours of this Committee will lead to a complete change in the antiquated and bad policy of every university and medical corporation in this kingdom.

THE

London Medical & Surgical Journal

Saturday, May 3, 1834.

NEW CLAIM OF THE LONDON UNIVERSITY.

We have always offered a steady and uncompromising opposition to the grant of the power of conferring Medical Degrees to the London University. Every occurrence since the question was first mooted has confirmed our original opinion, that it would be most unadvised to concede to it any such power; and that, in fact, there was not the slightest chance of its succeeding in the attainment of this object. We regret, therefore, with the feeling of true friends to the Institution upon general grounds,—we deeply regret, that the Council has, notwithstanding this certainty of failure, thought proper to persevere in its extravagant demands before the Privy Council. It should have seen that it was raising a storm of opposition not easy to be allayed; and that, in the effort to counteract its injurious claims, the legitimate objects, for which it had to contend against unflinching antagonists, were likely to be hazarded. The resistance of the medical profession is almost unanimous. Parties who agree in nothing else, are, in this respect, of one accord. Discontented friends appear to figure in the ranks of sworn enemies. With the declared sentiments of the medical profession before it, the Council should not have aggravated, by fruitless perseverance, the great difficulties it has to contend with from other and more implacable quarters,—from the spirit of party, of jealousy, of monopoly, and,

worst of all, from the spite of theology, the unrivalled odium *theologicum*. With another difficulty it has to contend, which has not escaped the scrutiny of its bitter enemies, and which it has forced into the mouths of its friends by its indiscreet demands;—we mean that the London University is nothing more, after all, than a joint-stock company, whose shares are at this moment in the market at a very great discount. Of this fact there is no doubt; and it certainly is not desirable, if it can be avoided, that an University, about to be chartered, should be in such a condition. It might be possible, perhaps, to vest the patronage of the professorship in a small select body, qualified by education to exercise such an important duty as the appointment of Professors, and above all suspicion of being influenced by unfair motives in their choice. This point might, for the present, be satisfactorily arranged. But, as long as the University was indebted to a number of persons, actuated by the common motives of creditors, however generously and kindly the present proprietors may be disposed, there is much room to doubt of the stability of the corporation. It cannot be expected that a charter will be granted for the mere purpose of raising the price of the shares in the market. The proprietors cannot desire or expect to reap any pecuniary profit from the acquisition of this valuable privilege. We suggest, therefore, whether they ought not to reduce their shares from their nominal to their real value; and, if the gift of the shares at their present low price is considered by the proprietors too great a sacrifice for such a national object as the establishment of an University in the metropolis, they have no right, at least as against the funds which might accrue from the possession of the general

privilege of incorporation they are suing for, to value their property at a higher rate than it now bears.

However satisfactorily this great objection may be disposed of, there still remains an insuperable obstacle to its claims to become a medical corporation. When we call to mind under what circumstances these claims are now urged, the charge of indiscretion is almost too mild a form of rebuke for the Council. We ask, where is the decency of urging its suit at the present moment, when every medical corporation in the kingdom is undergoing the rigid investigation of a Parliamentary Committee,—when it is admitted that our whole medical legislation is at fault, and the profession is confidently expecting a thorough reform in every branch? Is this a time for the London University to set forth its claims for an equality in this respect with Oxford and Cambridge, when the very privileges of these ancient bodies are gasping for existence? or if we make the distinction of the Council, between “a license to practice and a degree, which is an academical title of honour;” is it to be endured, that a particular association of teachers in this vast city, without any pre-eminent title to distinction from their brethren, should possess the privilege of giving to their own pupils a peculiar mark of honour, to pass current as the test of superior qualification? The Council, after having committed itself by its indecorous haste to clothe the University with this privilege, so insulting to the other schools of the metropolis, expresses its willingness to doff its garb of honour, should the Parliamentary Committee come to the resolution, in the course of a few months, as we have no doubt it will, that the medical profession should be incorporated by itself, apart from all Universities for general instruction.

“If, after the investigation of the Committee, it should be enacted that these degrees or certificates of superior attainment should be granted only by a Central Board of Examiners, and that the existing Universities should be deprived of the power of conferring them, the University of London would not desire to possess a privilege confided to no other body of teachers, and, if in the previous enjoyment of such a privilege, would be ready to resign it. But if this be the plan adopted, the senate is of opinion, that the examinations for conferring degrees should be entirely separate and distinct from the examinations for granting a license to practise; and the candidate for a medical degree should be required to give a full and satisfactory proof of a sound general education.” Such is the statement of the Council, in the pamphlet alluded to in our last number. The modesty evinced in this passage is heightened by the liberality exhibited a little after, where the Council (or rather the Senate, whose opinions it has adopted) declares, that “if any other establishment for medical education shall seek the same privilege of conferring degrees, and shall be able to give the same security for the general education, and for the medical proficiency of its pupils, the University of London will not imitate the example of the existing Universities, by opposing so reasonable a claim.”

In the course of the argument before the Privy Council, the difficulty here attempted to be obviated was stated by the Lord Chancellor in such a forcible manner as to drive the learned counsel for the University (Dr. Lushington) into a deviation from the tenor of his instructions, which places this pretended liberality in a new light.

“Supposing,” said his Lordship, “the power of granting degrees were to be

possessed, would not King's College, St. Bartholomew's, St. Thomas's, Guy's, and other similar schools, have a right to say, why were these privileges to be confined to the pupils of the London University? They could only qualify for a degree in that establishment. Or suppose Dr. Lushington were to say that they did not desire exclusive privileges; let King's College possess a separate charter from the crown; give the same to other hospitals: and might not this objection be met by another? Would not the establishment in Windmill-street and others put in their claims for similar rights? and might not this succession of claims reduce the value of a doctor's degree below zero, as was the case in some of the Scotch degrees, as those from St. Andrew's? The degree of doctor obtained from Edinburgh was as good as that from any other school. Next came that of Glasgow, and then Aberdeen. This was not so formerly, but it was better now. But St. Andrew's at present still was very low. Would not the remedying of that objection lead to the lowering of the value of the degree?"

This objection, arising out of the "reasonable claims" of the other London medical schools—claims certainly as reasonable as that of the medical school of the London University—did not occur to the Senate in composing their statement. The learned counsel for the University observed that it was unanswerable, and with admirable adroitness shifted his ground; and in order to evade the consequence of a multitude of degree-conferring bodies in the metropolis, declared he would be content to place the London University *at the head* of the medical profession, and on these terms he would admit the subordinate schools to share in its privileges as parts of the whole.

Dr. Lushington held "that the degrees must be distributed generally to all students, and not be confined to those of the University only; that something like a Metropolitan University should be established for this object, which presented itself in the London University, which would be open to all. As to medical examiners, these," continued the learned counsel, "might be selected from every one of the great schools, and all persons who studied in these schools should be at liberty to be candidates for the degrees. By adopting this course, no injury would be done to these schools, because every person studying in them would have a clear right to appear as a candidate for the honours; and, at the same time, by conferring the power of granting the degrees on one body, they would be preventing that which was to be so much deprecated, namely, the depreciation of the value of the distinction conferred."

The senate, in its extreme liberality, never dreamed of such an amalgamation as is here set forth. The idea of treating all other medical schools as off-sets of the University of London, and "in connexion" with it, was rather too arrogant even for its taste. It was evidently the last resource of a clever advocate, who felt that he was foiled in his immediate object.

The argument before the Privy Council, of which we have given a specimen, will be continued in the latter part of this week. We have no doubt of the result. The University cannot have the privilege it lays claim to. Meantime, we have felt it our duty to notice the *new* position the question has assumed.

INFANTILE MEDICINE IN PARIS.

It is a remarkable fact, that Paris is the only capital in Europe that has an hospital especially appropriated to the diseases of children;

from two to fifteen years of age. We are still obliged to have recourse, in the study of these maladies, to the obsolete works of Underwood and Rosen, which are but a continuation of the nosography of Pinel. A translation from a German author, named Henke, has been published, which may be considered in the same point of view. Three parts of the work of Henke are on the diseases of new-born infants, and in these we consider the treatise of Billiard superior to the German author's.

PROPHYLACTIC POWER OF BELLADONNA AGAINST SCARLATINA.

DR. KILLENKAMP gives the result of his experience on the efficacy of belladonna in preventing scarlatina in Hufeland's Journal for March, 1831. He states that during the prevalence of an epidemic scarlatina he exhibited the medicine to 120 children, from one to six years of age; 20 or 30 took it irregularly, and 25 or 30 did not take it at all. Of the first, five contracted the disease; of the second, eight; and the last, eleven. Of those who died none had taken the remedy. The formula was two grains of belladonna to an ounce of canella water, of which one drop was administered night and morning for every year of the child's age.

Reviews.

The Principles and Practice of Obstetrics, as at present taught by James Blundell, M.D., Professor of Obstetrics at Guy's Hospital. In Five Parts. To which are added Notes and Illustrations. By THOMAS CASTLE, M.D., F.L.S., Member of Trinity College, Cambridge, &c. &c. 8vo. pp. 838. London, 1834. Woodcuts. E. Cox.

The profession is much indebted to Dr. Blundell for these admirable lectures, which first led the great body of practitioners, in this section of the empire, to the study of obstetrics. The edition before us gives his last course of lectures, and contains a vast number of notes added by Dr. Castle, which enhance the original as a work of reference. The celebrated professor cited very few of his contemporaries, either domestic or foreign, and this omission is now supplied. The work is one of authority and reference. There is no point of practice

which is not clearly and admirably described. The introduction of Smellie's plates will prove instructive to students and young practitioners. We are gratified to see our term obstetrics adopted by so eminent a professor; he too was the first to sanction another of our terms, obstetrician, as a substitute for that barbarism man-midwife. We need not recommend this work, for every practitioner will possess it.

The Anatomy and Surgery of Inguinal and Femoral Hernia, illustrated by Plates, coloured from Nature. By E. W. TUSON, F. L. S., Assistant Surgeon to the Middlesex Hospital. Folio. London, 1834. J. Churchill.

THIS work admirably illustrates the important class of diseases to which it refers. It is so arranged, that every layer of tissue, from the common integuments to the hernia, is shown by raising successive plates. The work is extremely valuable to the operative surgeon, and such a one was much wanted. The author has very largely contributed to the illustration of descriptive and surgical anatomy, and the production before us must add considerably to his reputation.

DR. GRAVES ON THE MODERN GERMAN WORKS.

Utility of Iodine in certain Strictures of the Urethra.

DR. TRUSTEDT, contributor of many interesting clinical observations to the Berlin Medical Newspaper, has made some excellent remarks upon the employment of iodine in certain cases of stricture. I shall give them in his own words.

"On the 25th June, 1832, a patient was admitted into hospital; he had a gonorrhoea in 1830, and for the last six months laboured under the effects of stricture of the urethra, combined with a very considerable and painful tumour of the prostate, a urinary fistula which opened in the perinæum near the root of the penis, and an extremely large swelling of the left testicle, and spermatic chord, whose tumefaction could be traced to the abdominal cavity. The introduction of the bougie caused excessive pain and irritation, producing an increase of swelling in the affected parts above enumerated; I was consequently obliged to aban-

don all further attempts at dilatation, and confine myself to an antiphlogistic treatment. When the violence of the inflammation had to a certain degree subsided, I determined to try the effects of iodine, for it struck me that its peculiar effects on the genital system, and its well-known influence in producing absorption, might render it a valuable remedy in such cases. The patient took five drops of the tincture of iodine three times a day, and rubbed into the swollen parts a small portion of the ointment of hyd. of potash, morning and evening. Soon after the commencement of this treatment the swelling began notably to decrease, and the testicle and spermatic chord were, in a comparatively short time, reduced nearly to their natural dimensions. The swelling of the prostate now also began to yield, and diminished so much in eight weeks, that a bougie, carefully introduced, occasioned but little pain. The internal and external use of the iodine being continued, the patient's state became gradually better, and from time to time the introduction of bougies was cautiously repeated and their size increased. The difficulty of making water now rapidly diminished, and the patient was at last enabled to pass it in an uninterrupted and tolerably copious stream; the urinary fistula in the mean time closed up spontaneously, and the patient left hospital on the 11th of September, nearly cured.

"The happy effects produced in this case determined me to pursue the same plan in a man sixty years of age, who had been afflicted for nearly thirty years by a stricture and urinary fistula, connected with and depending on the stricture. He had in vain consulted the most eminent surgeons in France and Germany. In this case, apparently so inveterate as to be hopeless, the same method of treatment was remarkably beneficial, for in a few weeks the urethra became more dilatable, and the stricture permitted the passage of bougies of an increased size. A cautious perseverance in these remedies produced a notable expansion of the stricture, and in the same proportion he was able to pass water in a fuller stream, and with less irritation and difficulty. In this patient also, I had occasion to observe with pleasure the spontaneous closing of the fistula, and the mitigation of most of his sufferings. The stricture, it is true, although improved, was not cured; he nevertheless

had occasion to congratulate himself: upon obtaining a degree of comfort much greater than he ever hoped for, having before tried so many plans of treatment without benefit.

"The advantages of the method of cure I have recommended were still more strikingly displayed in a third inveterate, but less complicated case. The patient was thirty-nine years of age, and suffered, for the last eight years, great inconvenience, in consequence of a stricture, situated about four inches and a half from the orifice of the urethra, and which rendered the passage of water extremely tedious and difficult. I made many and ineffectual efforts to pass instruments, but could not on any occasion succeed in passing through the stricture even the smallest catgut bougie. I therefore desired him to use the iodine, both internally and externally, and in the course of a few days I had the gratification of being able to pass a small bougie. The same remedies being continued, the stricture became more and more dilated, so that the size of the bougies being gradually increased, I could, at the end of six weeks, pass into the bladder a bougie of the natural size of my patient's urethra. He could now make water without pain or difficulty, in an uninterrupted stream of the natural size."—*Dublin Journal of Medical and Chemical Science*.

Contraction of the Uterus after Death.

The following case, communicated by Dr. Trüstedt, is interesting:—

"A woman who was under the care of Dr. Rudolphi died suddenly, at an advanced period of pregnancy, in consequence of an attack of *febris intermittens apoplectica*. Her death took place about four o'clock, P.M., in an hour after which she was removed from the bed, and placed on some straw on the floor, covered with a sheet. A woman, left in the room to watch the corpse, was, about midnight, greatly alarmed by hearing a noise proceeding from the part of the room where the body lay, and immediately alarmed the house, being persuaded that the deceased was coming to life. On examination, a full grown dead child was found between the legs of the mother."—*Op. cit.*

Superfestation.

A married woman, twenty-two years of age, was brought to bed of twins in the lying-

in hospital at Berlin, on the 26th of January, 1832. The children were both girls, and died in two hours after their birth: their birth took place before the end of the seventh month from the date of pregnancy. One child was white, the other evidently a half caste, as was indicated by the shape of its head and the leaden tinge of its face, hands, and feet, which in colour resembled those who have been tinged by taking nitrate of silver in large doses. The same difference of colour was strikingly evident in the umbilical cords of the infants! but not in the membranes or placenta. On inquiry it appeared that she was in the habits of intimacy with a negro, shortly after or at the time she had conceived by her husband.—*Dublin Journal of Medical and Chemical Science.*

PROGRESS OF VACCINATION IN FRANCE IN 1832.

BY M. GERARDIN.

M. BARREY, who vaccinated 1061 individuals in the department of Doubs, has remarked, that a great number of these vaccinations failed during the heat of summer. From the month of October they improved, and for five months M. Barrey succeeded in almost every instance.

M. Damian, who vaccinated 600 persons in the canton of Lodeve, has observed anomalies in vaccination, which he attributes to great atmospheric variations, humidity having generally prevailed, sometimes with cold, sometimes with heat; and during summer and autumn an epidemic scarlatina attacked almost all the children. Notwithstanding this, vaccination progressed with regularity through its different periods, except that in taking the vaccine matter it was necessary to observe the evolution of the pustule, and wait until the tenth or twelfth day. Besides this circumstance, the circumference of the retarded vesicle was less extended, and the areola less marked. A great number of vaccinations failed, and those that succeeded were frequently attended with boils and swellings of the axillary and cervical glands. M. Damian remarks, that these observations confirm the opinions of those who, in vaccination, attend to the state of the atmosphere and the season of the year.

Undoubtedly, in the greater number of cases, the mildness of the disease is such, that this influence is imperceptible; but should we, on this account, deny its existence, when it is so well marked in the study of all eruptive and cutaneous diseases?

M. Parer, at Ille (Eastern Pyrennees), has also remarked the retarded appearance of vaccination. In a great number of cases the disease did not commence until the tenth, and sometimes the fifteenth, day. He also experienced more resistance to the action of the virus than in the preceding years, so that he was obliged to vaccinate the same individual two or three times.

In the Loiret, on the contrary, M. Pellioux, of Beaugency, has observed that the physicians never saw vaccination assume such a marked form as during the latter months of 1831 and the first half of 1832. In almost every case, the number of pustules equalled that of punctures, and scarcely any of that resistance to the development of the vesicles. At the end of the third or fourth day, vaccination advanced with a vigour and rapidity quite remarkable, but without any confusion. The seventh day after vaccination the pustules were from three to four lines in diameter, the base was extended, the circular pustule was large, prominent, and filled with an abundant fluid; the central depression was of a deep colour, the areola from four to five lines in extent, presenting a fine vermillion colour; the fluid collected in tubes and sent to a distance never failed in its effect; in a word, the seventh day from vaccination, the pustules had the same appearance that is usual on the ninth or tenth day of the most favourable vaccination. Without endeavouring to explain the phenomena, M. Pellioux remarks, first, that these vaccinations had taken place in winter or at the beginning of spring, whilst it is usual to vaccinate in spring and summer; secondly, that previously he had always vaccinated in the absence of epidemic small-pox, though at this time he operated while that disease was very prevalent; and, lastly, there prevailed at the same time numerous inflammatory cutaneous affections, such as chicken-pox, nettlerash, measles, pemphigus, ecthymæ, erysipelas, and furunculi.

M. Tueffard, of Montbelliard, has transmitted a memoir "on vaccination, and small-pox

occurring afterwards," in continuation of one presented in 1818. There are some singular facts stated, which we shall notice in our next.

French Hospital Reports.

HÔTEL DIEU DE BOURDEAUX.

Cerebral Affection—Administration of Sulphate of Quinine—Cure.

A ROPEMAKER, named Hugues, of a nervous temperament, had invariably enjoyed good health up to January, 1833, when he was seized with cephalalgia and general disturbance of the system. At the end of eight days, the pain in the head having continued all the time, he became violently delirious, from which he recovered, having been put under severe antiphlogistic treatment. Six months afterwards he again fell into the same state, did not recognise his relations, and struck his wife and others who attempted to approach him. On the 4th of January he was admitted into the hospital, under M. Dutrouille, labouring under the following symptoms:—Intense frontal cephalalgia, injection of the conjunctiva, distortion of the left side of the mouth, convulsive movements of the muscles of the face, numbness of and inability to move the left limbs, small quick pulse, abundant nocturnal perspirations, attended with aggravation of the symptoms, digestive system healthy, pupil neither contracted or dilated.

Six grains of sulphate of quinine, with infusion of valerian, were given to him on the 6th, the medicines which were previously ordered having done no good.

7th. The agitation and convulsive motions have been less during the night.

These medicines were given daily up to the 11th with marked amendment; the cephalalgia diminished, the delirium left him, and the contraction of the muscles disappeared. On this day he again became worse, and was seized with violent pain in the left middle finger and increase of the numbness in the remainder of the hand. The remedies were notwithstanding persisted in, and he soon afterwards became again better.

He continued to take the sulphate of quinine up to the 21st of the month, on which day he was discharged cured. About a fortnight after this time he was again attacked

in the same way, and was again cured by the same remedies.

Violent Contusion of the Left Knee—Extensive Effusion into the Joint—Compression—Cure.

Related by the Patient, M. A. SECRETAIN, Surgeon to the Hôpital d'Ebrevil.

On the 20th of Jan. 1832, a horse, on which I was riding, ran away, and struck my left knee against the wheel of a carriage. In a very short time the joint had acquired double its ordinary size, and was excessively painful. Repeated applications of leeches, quiet, and cataplasms caused these symptoms to disappear in the course of the month; but, on attempting to walk, the swelling returned. Leeches, blisters, douches, &c., were now used, but without obtaining any diminution of the superabundant fluid. A month elapsed without any amendment, and I began to despair of a cure; but, pressure being suggested to me, I constructed some graduated compresses, which were placed round the joint, and there retained with rollers. The continued use of this mode of pressure, and the occasional use of douches, have at length (March, 1833) effected a cure.

Hemerolopia caused by Quartan Fever—Cured by Sulphate of Quinine.

The infant of M. Sudreau, aged three years, was attacked with well-marked quartan fever. After the second paroxysm, the parents perceived that in the evening, near sunset, the child could not see, but did not appear to suffer any pain in the eyes. Its sight returned in the morning; but in the evening, about the same time, again failed so completely, that it could not even perceive the candle when placed close to its eyes. A week thus passed, the hemerolopia returning daily; the pupils were dilated, but movable. With the exception of the blindness, the infant did not appear to suffer. Blisters, &c., were used, but without avail, the hemerolopia and fever continuing. Forty days after the appearance of the fever, I ordered ten grains of sulphate of quinine in a potion, which was to be taken in four days. By persevering for the space of sixteen days in using this medicine, the paroxysm of fever disappeared, and two days afterward the hemerolopia was also gone.

**HÔPITAL MILITAIRE D'INSTRUCTION
D'ALGER.**

***Gun-shot Wound of the Thigh—Amputation
—Torsion—Cure.***

J. —, a soldier of the 59th regiment of the line, whilst disembarking at Bougie on the 1st of October, 1833, received a ball in the lower part of the thigh, which penetrated into the coxo-femoral articulation. On the 12th, when the military entered Alger, this man's thigh was swollen to more than double its volume. The suppuration in the wound was abundant. He complained of thirst, heat of skin, pains in the epigastrium, and loss of appetite. His pulse was full and frequent, tongue red, and bowels constipated. Although these symptoms were so unfavourable for an operation, M. Baudens amputated on the following day, considering that to temporise in such a case was to deprive the patient of the little chance of success which yet remained to him. Torsion was used to restrain the bleeding from the femoral artery and a large muscular branch. All went on well for eight days; at the end of this time union by the first intention had not taken place, although the edges of the wound were in apposition. By means of stimulating applications, and pressing the parts close together, the wound cicatrised, and not long afterwards the patient was discharged cured.

Gun-shot Wound—Injury and Ramollissement of the Great Sciatic Nerve and its Branches—Death—Autopsy.

B—, a soldier of the 1st African Battalion, æt. 26, on the 20th of July, 1833, received in the middle of the right buttock a ball, which, after having taken a course of about eighteen inches, presented itself at the inferior part of the thigh on the outside of the sartorius muscle, some of the fibres of which were ruptured. Three hours after the wound an examination of the injury was made, when it was found that the ball had passed close to the popliteal artery, without injuring either it or the bone. From the situation and extent of the wound, it was to be feared that there was lesion of the great sciatic nerve, and of the saphena interna, but a thorough examination

could not be made, in consequence of the excessive pain which it gave the man. There was nervous hæmorrhage to a great extent; the pulse was feeble; his body was covered with cold perspiration, and his face had become pallid and altered in expression.

Compresses and warm fomentations containing opium were applied, and succeeded in arresting the flow of blood, and in assuaging the pain which for the first thirty-six hours had been excessive. Slight reaction took place, but not sufficient to prevent mortification, which destroyed the patient in forty-eight hours.

Autopsy.—Several of the large branches of the femoral artery were wounded; the internal saphena nerve was grazed, and the peroneal branch of the sciatic was divided and gangrenous at the wounded ends. The neurilema appeared inflamed as high as the lumbar plexus, and as low as the leg. The popliteal branch of the sciatic was entire; but opposite to the superior opening of the wound, and for an extent of four inches, its tissue was softened and in a purulent state. The parts surrounding the course of the ball were much lacerated, and in a gangrenous state.

Gun-shot Wound of the Right Peroneo-Tibial Articulation—Erysipelas—Cauterisation—Cure.

L—, æt. 20, a private in the 59th regt. of the line, was wounded at the superior articulation of the right fibula by a ball, which caused extensive laceration of the ligaments. When M. Baudens saw the man, eight days after the accident, there was slight reaction, but his pulse was still much depressed and frequent. The head of the fibula, which was bathed with suppuration of a bad character, was almost entirely reduced to fragments; but the tibia did not appear to have participated in the injury. Erysipelas to a great extent had invaded the whole of the limb, which was thereby rendered nearly double the size of the opposite leg. As the state of the patient did not seem to warrant the employment of antiphlogistic treatment, recourse was had to cauterisation, employed with so much success by M. Larrey. The erysipelatous surface of the skin, slightly touched with a hot iron, became of a white colour;

reaction took place, the erysipelas disappeared, granulations appeared over the surface of the wound, and at the end of two months the man was discharged cured.

Remarks.—M. Baudens considers the above case worthy of relation, for the purpose of directing the attention of practitioners to the employment of cauterisation in erysipelas. He has employed nitrate of silver, blisters, compression, and mercurial frictions successively, but thinks the actual cautery much the most efficacious method of arresting the inflammation, even when it partakes of a phlegmonous character.

Acute Hydrocephalus treated by Mercurial Frictions—Copious Salivation—Cure.

Levi, aged 26 months, of good constitution, was attacked, March 16, with slight rigors, loss of spirits and appetite, and bilious vomiting, which continued through the following day. When seen on the 18th, she presented the following symptoms:—she was faint, inclined to drowsiness; scalp hot; pulse 110; nausea; tongue loaded in the centre, but red at the tip; slight tenderness at the epigastrium. Infusion of mallows to be given; six leeches to the anus.

19th, 20th. Skin less hot; pulse 103; no vomiting. The treatment to be continued, omitting the leeches.

21st. Stupor; hot scalp; pulse 140; subsultus tendinum. Six leeches to the anus, and four to the temples; mild sinapisms to the feet.

22nd. Coma; pulse 130. Four leeches to the epigastrium, and four behind each ear; towards evening two blisters to the thighs. In the night she became worse, with coldness of the extremities, cold sweats, thready and frequent pulse. Bottles of hot water to the extremities, hot fomentations to the abdomen.

25th. Extremities cold; profound coma; pupil contracted; pulse 135. Two grains of calomel to be given every hour. Ung. hydrarg. 3 ss. to be rubbed over the sub-maxillary region three times in the course of the day.

24th. Much the same; copious salivation. A blister to the occiput; eight grains of calomel to be given during the day, with two mercurial frictions at night.

25th. Coma gone; extremities warm; pulse 112. She had three green stools.

From this time the child improved rapidly; and on the 29th was in a state of convalescence.

British Hospital Reports.

ST. GEORGE'S HOSPITAL.

Clinical Remarks by Mr. Brodie.

THERE are at present two female patients in the hospital under the care of Mr. Brodie, with enlarged bursæ of the patella. The treatment employed was to plunge a sharp pointed bistoury through their substance, and cut them through upward, and poulticing them for a few days, and then dressing them with lint from the bottom to excite granulations to spring up, which were further stimulated, if found necessary, by the occasional application of the caustic potash. Under this treatment they are rapidly healing, and Mr. Brodie took occasion to make the following remarks upon them at the bedside of one of these patients.

“In the natural state the coats of such a bursa as this which you have just seen me lay open, are very thin, and can scarcely be examined unless they are dissected very carefully; but when much pressure is exerted on them by kneeling (forming what is commonly termed ‘the housemaid’s knee’), three distinct changes take place. First, there is an increased deposition of serum, or synovia, in the cavity of the bursa; secondly, the walls of the bursa become much thickened in substance and texture; and, thirdly, there is deposited on the inner lining membrane from inflammation a layer of coagulated or coagulable lymph, which, in an advanced stage of the disease, become organised, and by friction and the motions of the joint become broken down into portions and rounded masses, known (from their shape and appearance) by the name of melon-seed bodies. With respect to the treatment of such bursæ in the early stage, before the inflammation has proceeded to any great length, it is a good practice to apply leeches and cold lotions, and afterwards perhaps a blister. In the more advanced stages, as in the present case, it is the best plan to

lay them open with a scalpel, and let out the serum, or synovia, which they contain, and dress them to the bottom with lint, thus to excite granulations to spring up from the internal surface of the lining membrane, and to cure them in the same way that an old hydrocele is cured. There is, however, another and a third stage, in which such bursæ as these are found, wherein the thickness of the coats of the bursa is equal to the length of a nail (!), and the quantity of fluid which the cavity contains is necessarily very small. In such cases the best treatment which you can adopt is to dissect the parts completely out with a scalpel. It would be supposed that when such a plan as this is followed the bursa would never be regenerated; but a case of this kind occurred at this hospital some years ago, under the care of the late Mr. Rose, who extirpated the bursa completely; it returned, however, again, and again went through all the morbid processes of thickening, condensation, &c., and I removed the bursa again.

"Bursæ, though small, are sometimes the cause of very great pain, as when they are situated under the hard horny substance of a corn, and they inflame, and matter is formed in them, which is pent up by the thickened surrounding structure. I was once called to see a lady, whose foot, ankle, and leg were very much swollen and inflamed, and she herself in the greatest agony in consequence. I found that all this mischief and pain arose from an inflamed bursa of the little toe, situated under a hard corn. I pared this away, and there came out of it two or three drops of pus, which relieved her very much, and the next day when I saw her she was quite well. A bunion is nothing more than a hard thickened portion of cuticle, generally on the inside of the foot over the articulation of the metacarpal bone with the first phalanx of the great toe. At this point there is no bursa naturally, but an artificial one becomes formed in time by the pressure of the shoe over this part. You will sometimes find an inflamed bursa underneath a corn on the joint between the first and second phalanges of the second toe. This is caused by the tight shoe pressing the toes so closely together that they overlap one another and press the joint upwards. The best method of remedying this is to strap some adhesive plaster over and under the toes, so as to bring them all upon a plane. The soft corns that form between the little toe and the adjoining one, arise from these being pressed so close as to overlap one another. These are best remedied by putting a piece of strong buff leather between the toes to keep them apart, and to take off pressure at the same time."

Tumours of the Breast—Scirrhus.—"These tumours are often very difficult to distinguish from scirrhus. A medical man, who had great experience in such cases, once brought me a patient who had a tumour of the breast,

which he mistook for scirrhus, and for the removal of which he expected that I should recommend an operation to be performed. I examined the case attentively, and then told him that if it was scirrhus it was one of those cases in which amputation would do no good, and recommended him to try the liquor potassæ, which he did, and his patient entirely lost the tumour. I saw another case of tumour, which was dispersed by the use of the liquor potassæ; it was persisted in, however, for thirteen months. I have frequently seen a wasting away occur from the long use of this medicine, but I never saw any thing like pyrosis."

Pains in the Bones.—"In venereal affections you will find that sarsaparilla in decoction or powder will tend materially to relieve the unpleasant symptoms of pains in the bones. Guaiacum is also a very valuable medicine in such cases; the powdered root of the *manisotum* also, and iodine."

Disease of the Testicle.—"This a case which I believe is simply one of hydrocele; the patient, you see, has none of the symptoms of malignant disease. There is a thickening of the tunica vaginalis, and you may also feel a hard ridge on the anterior and inner side of the body of the testes. I once had a patient in whom I also noticed this hard ridge; he died of some internal complaint afterwards, and on examining his body after death, I found that there was no malignant disease of the testicle. If there be hydrocele and malignant disease also, and you do nothing for the latter, the consequence will be that repeated abscesses will form in the body of the testicle and burst. If this state of parts has commenced, you may stop it by giving the patient small doses of calomel and opium until his system is completely under its influence: and if not commenced, you may prevent it by using the same means. This man, you see, does not feel at all faint or sick from the injection, the reason of which is, that I have not filled the tunica vaginalis so full as to distend it, and thereby to press upon the testicle, which pressure is in these cases the cause of the faintness and sickness which the patient feels."

"It is not necessary that new bone should be formed before you take away diseased bone in cases of necrosis; the patient will get very well; the diseased bone being *detached*, forms, of course, no support with the surrounding parts."

"Many of the common coughs with which patients are affected do not arise, I believe, from the lungs at all, but are caused by irritation of the mucous membrane of the larynx. I once examined a person after death who had been subject to one of these teasing, harassing coughs: the lungs were found perfectly sound, but the lining mucous membrane of the larynx was studded with numerous little vascular tubercles, having evidently consisted originally of small masses of coagulated lymph, which had become organised."

ROYAL COLLEGE OF SURGEONS.

NAMES of Candidates who received Diplomas during the month of March, 1834.

George Northon Foaker	. Colchester.
Edmund Mills	. Dublin.
Robert Webb Bradshaw	. Dublin.

BOOKS.

The Liverpool Medical Journal, published monthly, under the superintendence of an Association of Physicians and Surgeons, chiefly attached to the Medical Charities of Liver-

pool. No. I. May, 1834. London: Henry Renshaw. Liverpool: W. Grappel.

This is a clinical Journal, containing several instructive reports which we shall notice in our next.

CORRESPONDENTS.

Professor Lizars.—The Committee-room is filled with communications, and the excellent Chairman received the information suggested, which, like every thing else, has already been turned to account.

Dr. Blake's communication in our next.

Medicus, A Friend, A Reformer, and others are informed that we should commit a breach of privilege by publishing the evidence given before the Parliamentary Committee.

An Inquirer.—It is impossible to guess at the intended changes in medical legislation; but there is every reason to believe that they will be most extensive.

A Surgeon.—We do not think that parish surgeons are too highly remunerated; indeed the Poor Law Commissioners record that this is the only moderate item in parochial accounts. It is a question, however, whether the poor would be as well attended, were they at liberty to apply to any surgeon in the parish, who would be entitled to ordinary remuneration from the overseers, as the medical officer of the workhouse. The Parliamentary Committee have turned their best attention to this as well as to every other question relating to medical education and practice.

A Licentiate.—We have seen the reply of the Fellows to the Licentiates' petition, which is a sad misstatement—a dying struggle.

An Impartial Reporter will receive our attention.

VOL. V.

LECTURES ON THE PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECT. LXXXVIII., DELIVERED APRIL 16, 1833.

GENTLEMEN,—I will next make a few observations on *Opacities and Specks of the Cornea*, which receive different names according to their degree and mode of formation. The slightest degree of opacity is termed *nebula*, in which the cornea presents a diffused cloudiness, a hazy or milky appearance, that has no distinct boundary, but is gradually lost in the surrounding transparent portion of that membrane. It is often accompanied by an enlarged and reddened state of the vessels of the conjunctiva, some ramifications of which extend into the delicate layer of this membrane, spread over the cornea.

Then, gentlemen, opacities of a more circumscribed and complete kind are exemplified in *Albugo* and *Leucoma*, which consist of a deep extravasation of a dense lymph in the substance of the cornea. They are of a clear white or pearl colour, and only differ in one respect, namely, that the *albugo* is the consequence of some description of ophthalmia, or of an abscess or ulceration of the cornea, while the *leucoma* is the opaque speck or mark occasioned by a wound of that membrane. For some time after the completion of the healing process it continues to diminish; but this improvement can only take place in a certain degree, and an indelible opacity will yet remain, though considerably smaller than the original wound which was the cause of it.

Numerous red vessels are sometimes observed running into an *albugo* from the conjunctiva, and, when this is the case, the opacity is apt to spread, and is somewhat raised above the level of the cornea, the delicate layer of the conjunctiva, spread over this membrane, being much thickened. This variety of *albugo*

is occasionally seen in scrofulous adults, and sometimes in children.

Gentlemen, as a general observation, I may say, that the remedies calculated to do good to specks of the cornea, in their early stage, are those which have the effect of removing the inflammation that has given rise to them. At the same time, there are both general and local means peculiarly adapted for hastening the absorption of opaque depositions in the cornea: such are mercury and iodine. We have likewise various applications for quickening the action of the absorbents in the removal of specks, if employed at the proper time. If you commence their use too soon, that is, before the cause of the opacity is removed, you will do more harm than good. For instance, if in an *albugo*, arising from scrofulous corneitis, and still attended by considerable vascularity, you were directly to attack the opacity of the cornea with stimulating powders and strong solutions of nitrate of silver, oxymuriate of mercury, or iodine, you would not only fail in accomplishing the object in view, but create a great risk of rendering the patient totally blind. But if you begin with attacking the strumous inflammation, which still lingers in the eye, and that chiefly by constitutional remedies, you will not only disperse the redness, but often find the cornea begin to become clearer from day to day, and the eyesight to be proportionally improved.

The best local applications for opacities of the cornea are, a solution of the nitrate of silver, from two to five grains, in an ounce of distilled water; a solution of one or two grains of oxymuriate of mercury in an ounce of distilled water; the *vinum opii*; the *ung. hydr. nitratis*; or a finely levigated powder, consisting of ʒj. of red precipitate and one ounce of white sugar. The latter is generally blown on the speck through a quill. The useful effect of iodine collyria I must also not forget. The vascular forms of *albugo* sometimes require the trunks of the vessels distributed to them to be divided, and mercury or iodine to be exhibited.

Gentlemen, *Staphyloma* is a term applied to various protrusions or projections on the front of the eye, in consequence of their fancied

resemblance to a grape, *staphyle* being the Greek word for that fruit. Thus, a protrusion of a portion of the iris through an ulcer, or wound of the cornea, used to be called *staphyloma racemosum*, but now more properly *prolapsus of the iris*. At the present time, the term *staphyloma* is usually restricted to protuberances of the cornea and sclerotica. Staphylomatous affections of the sclerotica, however, are so rare in comparison with those of the cornea, that it is only the latter which need detain us. When the cornea becomes staphylomatous it loses its natural transparency, rises above its proper level, and even projects between the eyelids, in the form of a whitish, pearl-coloured, or bluish tumour, attended, when the whole cornea is affected, with loss of sight. To this grievance are added, in bad cases, all the evils which unavoidably result from the projection of the cornea: inability of closing the eyelids; exposure of the eyeball to the air and extraneous matter suspended in it; irritation and inflammation from this cause and the friction of the eyelashes; and soreness and excoriation of the lower eyelid and cheek from the constant stillicidium lachrymarum. Even the other eye is often sympathetically affected, becoming tender, and sometimes truly inflamed.

Staphyloma of the cornea is either *partial* or *total*. Although the most evident symptoms are opacity and projection of the cornea, a common effect of the disease is adhesion of the iris to the diseased cornea, and consequently a diminution or total obliteration of the anterior chamber.

In those cases where a partial staphyloma neither covers nor involves the pupil, the patient may be able to see objects placed above him or on a level with his eye; but he is generally affected with epiphora and painful sensibility of the organ. In more unfortunate cases, all the margin of the pupil is adherent to the opaque and projecting portion of the cornea, and it is only by the formation of a lateral artificial pupil, that a degree of vision can be recovered.

Gentlemen, partial staphyloma is sometimes confounded with leucoma; but it is to be recollected, that in general the iris is firmly adherent to the whole extent of a partial staphyloma, but either quite unconnected with a leucoma, or connected to it by a mere point. In partial staphyloma, the whole cornea inclines to a conical form, the apex of which is the centre of the staphyloma; whereas, in leucoma, the general spherical form of the cornea remains unaltered.

If either from closure of the pupil, or from the partial staphyloma being situated over it, no vision exists, you should try to lessen the staphyloma itself, and then consider whether by an operation for artificial pupil the eyesight can be restored.

Now, the safest plan of reducing a partial staphyloma is to apply to its apex the muriate of antimony with a camel-hair pencil, while

the eyelids are kept widely separated. Then before the eye is shut, the surface of the staphyloma should be washed with a large camel-hair pencil dipped in milk. The caustic is not to be repeated, till the slough has come away, and the inflammation caused by the former application subsided.

In one form of total staphyloma, the tumour is *spherical*; in the other, it has the shape of a *blunt cone*.

As there is no possibility of restoring sight to a patient afflicted with total staphyloma, even in cases where the lens, vitreous humour, and retina are sound, the only thing you can usefully do is to lessen the protuberance of the cornea, which is not only a great disfigurement, but a cause of the serious annoyances already specified. This is done by an operation, which consists, first, in the formation of a flap with the cataract knife; and, secondly, in completing the circular excision of the most prominent portion of the tumour with a pair of curved scissors.

This may be easily done without the ceremony of first passing a ligature through the cornea, for the purpose of fixing and drawing it outward. The lens and vitreous humour generally escape; the eye shrinks into the orbit; and though the organ is destroyed, the patient is freed from a disease, which, besides being attended with total loss of sight, was a source of great misery and suffering.

Synechia, gentlemen, is a term employed to signify a morbid adhesion of the iris. When the adhesion is to the cornea, the case is called *synechia anterior*; when to the capsule of the crystalline lens, *synechia posterior*. The former is often the consequence of a wound or ulcer of the cornea attended with escape of the aqueous humour; the latter is more frequently brought on by iritis.

Partial and recent adhesions of the iris to the capsule of the lens may sometimes be separated by the use of belladonna and mercury. In some instances of partial synechia anterior, and even of complete synechia posterior, which is mostly attended with closure of the pupil, vision may also be restored by the formation of an artificial pupil.

The adhesion of the iris to the cornea produces a change in the size, position, and shape of the pupil; and when the result of inflammation or of a prolapsus of the iris, the cornea mostly becomes opaque, the speck more or less covering the pupil.

Prolapsus of the iris, sometimes termed *staphyloma racemosum*, is a protrusion of the iris through a wound or ulcerated opening in the cornea. It is necessarily of the same colour as the iris, brown or greyish, and its size varies from that of a pin's head to that of a small pea. As the cornea is rarely perforated at more than one point, the prolapsus is usually single, and its base is generally surrounded by an opaque circle of the cornea.

The inconveniences of a prolapsus of the iris are pricking pain in the eye, inflammation

of the organ, intolerance of light, a deviation of the pupil towards the seat of the prolapsus, and a lessening of its diameter. In cases of long standing, the protruded portion of the iris becomes less sensible, and the distress experienced less acute.

When the prolapsus is quite recent, and the consequence of a wound, no doubt can exist about the propriety of reducing the iris into its right situation again. In other examples this is impracticable, and then the inconveniences of the projection of the iris are to be relieved by touching the tumour repeatedly with the nitrate of silver, until it is sufficiently levelled and the ulcer healed; while the obstruction of vision itself, caused by the displacement and alteration of the pupil, and the partial opacity of the cornea, may sometimes be removed by the formation of an artificial pupil. When the tumour of the protruded iris is large, it may be necessary to snip off a part of it with scissors, before the nitrate of silver is applied.

Gentlemen, I will next make a few observations on the closure of the pupil and formation of an artificial pupil. A permanent contraction, or a closure of the pupil, is most frequently a consequence of inflammation of the iris; but sometimes it follows operations for the removal of cataracts, coming on slowly and insidiously at some indeterminate period afterwards, without any marked inflammation in the eye. The iris becomes motionless, assumes a radiated wrinkled appearance, and, when the lens is free from opacity, a small black point is seen in its centre. Under these circumstances, if the retina be sound, the patient may sometimes regain a considerable power of vision by the formation of an artificial pupil. The pupil may also be obstructed by the effusion and organisation of coagulating lymph from inflammation; or you may have such a displacement of the iris from prolapsus as causes an alteration in the shape and position of the pupil, attended with serious obstruction of vision. You are already aware, that synechia anterior is frequently attended with opacity of the cornea.

The several varieties of the operation for the formation of artificial pupil may all be referred to three principal methods; the first is a *simple cut through the iris*, without the removal of any portion of it, termed *coretomy*. The second is an incision in the iris, and the removal of a part of it, *corectomy*. The third consists in separating some of its external margin from the corpus ciliare, *coredialysis*.

The changes preventing the passage of light through the pupil, and requiring the formation of an artificial pupil, I have already described; but, gentlemen, it must be manifest to you, that such an operation could not be performed with a reasonable prospect of success, unless the changes in the condition of the pupil were the only defect in the eye. Thus, unless the retina were sensible, it would be doing no good to make a new opening in the iris. The patient should always be capable

of discerning the difference between light and darkness; and, if he had not this power, the operation would hold out little prospect of success. This state, however, does not amount to an absolute prohibition of it, because sometimes the iris is so thickened, and the posterior chamber so full of dense lymph, and the transparency of the lens is so affected, that the power in question may be annihilated, yet the retina itself not be incapable of resuming its functions. The experiment, though unpromising, may be made.

An artificial pupil should never be formed in one eye, as long as the patient is able to see with the other. Nor ought the operation to be attempted if the eye be affected with inflammation, preternatural hardness, dropsy, or atrophy.

When a part of the cornea is opaque, the place for the artificial pupil must of course be determined by the situation of the transparent portion of that membrane; and if the operator has the choice of placing it behind either the nasal or the temporal edge of the cornea, the former situation is to be preferred, as affording a more useful degree of vision.

Whenever the lens and capsule are transparent, one chief caution in the operation is to leave those parts completely undisturbed.

As an artificial pupil possesses no power of contraction and dilatation, care must be taken to make it neither too large nor too small. Too small an opening would not be very serviceable; and if it were too ample, the quantity of light admitted would dazzle vision, and the new aperture be comparatively useless.

Now, gentlemen, it is manifest that it would be impossible to describe, in a course of lectures on surgery in general, all the modifications of operations, rendered necessary by the infinite variety of circumstances attending a closure of the pupil. The state of the pupil itself, its being filled or not by opaque lymph, the condition of the cornea, the state of the lens, and the disease being complicated or not with prolapsus and adhesion of the iris, are several principal considerations influencing very much the particular mode of operating.

Coretomy, or the simple division of the iris, may be performed with an iris-knife, or couching-needle, that has a sharp edge only on one side; or else with a minute pair of scissors, one blade of which has a sharp point the other an end, like that of a small probe, such as I now show you. The iris-knife, which is also before you, is but little larger than a common couching needle. It is introduced through the sclerotica, about a line and a half from the cornea, and after perforating the iris on the side towards the temple, its point is conveyed across the anterior chamber nearly as far as the ciliary margin of the iris towards the nose. Then the sharp edge is to be turned backwards, and pressed against the iris as it is withdrawn, so as to make a transverse cut in the iris.

Another plan of dividing of the iris is per-

formed by making an incision near the side of the cornea, and introducing the small scissors, one of the blades of which has a sharp point, the other a probe point. The sharp point is then passed through the iris, near its ciliary margin, while the probe point is passed under the cornea, the requisite distance, when the blades are to be shut, and the necessary division of the iris performed.

These methods of operating are proper when the iris has a tense appearance, when the cornea is transparent, and there is no crystalline lens, or when the closure of the pupil has followed extraction of the cataract.

The *excision of a portion of the iris*, termed *corectomia*, is another method. It is performed in different ways. Thus, you may puncture the cornea, draw out a piece of the iris by means of a minute hook, made for the purpose, like what is before us, and snip it off. This was Professor Beer's way, which appears quite as good as that adopted by the late Mr. Gibson, who made an incision in the cornea, so as to let out the aqueous humour, after which he made a piece of the iris protrude by means of gentle pressure, and cut it off. The iris then receded into the eye with the new circular opening formed in it.

These last plans are proper when the centre of the cornea is densely opaque, but the whole, or a portion of its circumference, transparent, and the lens and its capsule sound.

The operation of separating a portion of the outer margin of the iris from the corpus ciliare, *coredialysis*, was first done by Scarpa, on the side towards the nose; but, as the opening did not continue to be permanent, this plan was abandoned in favour of Reisinger's method, which is executed by means of a very fine double hook forceps, capable of being put into the form of a single hook by slight pressure. A small puncture is made in the cornea near its margin, the double hook forceps introduced, and conveyed, with the points turned downwards, as far as the place where the iris is to be separated, but always as near as possible to the ciliary edge. The points are then to be slightly opened, and made to enter the iris. The blades are now to be shut, and the instrument slowly drawn outwards, by which means a sufficient piece of the iris will be detached, which, having been disengaged from the instrument, is to be left strangulated in the wound of the cornea. In fact, this operation is a combination of *coredialysis* with *corectomia*. In this country *coredialysis*, I believe, is not in much favour, and surgeons generally prefer either *corectomia* or *corectomia*.

Hydrophthalmia, or *dropsy of the eye*, seems, gentlemen, to be generally a local disease, or, at all events, is never connected with, or dependent upon, ascites, anasarca, or other dropsical affections, and, if it depend upon constitutional causes, they have not yet been satisfactorily made out.

You may have dropsy of the chambers of

the eye, that is, an increase in the quantity of the aqueous humour; or you may have a preternatural accumulation of the vitreous humour; or, lastly, you may have a collection of serous fluid between the sclerotic and choroid tunics.

The symptoms of dropsy of the anterior and posterior chambers are a greater prominence of the cornea than natural, and an increase in its diameter, attended in the advanced stages with loss of its transparency. The iris is soon rendered motionless, and of a darker colour than usual. At first, the eye is farsighted, but afterwards the power of seeing becomes considerably impaired, or lost. When this variety of hydrophthalmia follows injuries of the eye, it may be combined with a tremulous state of the iris, and partial amaurosis.

In the treatment, you may try blisters to the temple; or, behind the ear, mercury, and purgatives. In inveterate cases, paracentesis oculi has been proposed and practised.

With respect to the *Subsclerotic Dropsy*, if its existence could be made out, which would be a matter hardly practicable, the discharge of the fluid by puncture would be indicated.

Dropsy of the vitreous humour is attended with enlargement of the posterior part of the eyeball, a conical projection of the cornea forwards, advance of the iris towards the cornea, deep blue colour of the sclerotica, shortsightedness followed by complete amaurosis, the eyeball becoming hard and motionless.

As sight is totally lost, all that the surgeon can do is to relieve those inconveniences which arise from the distended state of the eye, and its pressure. A piece of the cornea may be cut off, and the humours discharged.

A general and considerable enlargement of the eye, from an accumulation of the aqueous and vitreous humours, is sometimes termed *buphthalmos*, from its resemblance to the eye of an ox.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XX.

Symptoms of Intestinal Worms—Various Sympathetic Irritations—Affections of the Nervous and Respiratory Systems—Exciting Causes—Verminous Fever—Treatment and Specific Mechanical Purgative—Use of Mercury, and Turpentine—Animal Oil of Dippel—Preventive Measures.

GENTLEMEN,—Let us proceed with the consideration of intestinal worms. At my last lecture you will recollect that I spoke of the different kinds of worms, and stated that there was a difference between the worms which are found in various parts of the body; that I examined the question as to the origin of these

animals, and came to the conclusion that they are formed originally within the bodies of man and other animals. I mentioned the various kinds of worms which inhabit the digestive tube in man, and examined at some length the question of perforation of the intestinal canal by lumbrici. We come now to the investigation of the symptoms.

With respect to the symptoms of worms, it is a singular fact, that we have not one single pathognomic sign of their existence, except the circumstance of their being occasionally passed by stool, or vomited; almost all their symptoms are referable to irritation of the gastro-intestinal surface, and its sympathetic relations. Persons, who are much subject to worms in these countries, are generally of a pale complexion, with a bluish circle round the eyes; the belly is more or less prominent, and there are various signs of irritation of the digestive tube, with itching at the nose and anus; headach; foul breath and tongue; irregular and sometimes canine appetite, nausea, hiccup, borborygmi, tenesmus, diarrhoea, and constipation. Though the patients take abundance of nutriment they are generally thin and pale, and in such cases there is either one or two very large worms, or a great number of smaller ones, or their presence is complicated with disease of the intestinal canal. Such persons are also observed to be of an indolent and languid habit; they have perspirations, disturbed sleep, with grinding of the teeth, and irregularity of pulse.

The sympathetic irritations, produced by worms, are numerous and extraordinary. The genital organs may be excited, and we may have priapism and seminal emissions in the male, and irritation amounting to nymphomania in the female. There is a very singular case on record of a female, aged seventy, being seized with a violent attack of nymphomania from this cause. The nervous affections, produced by worms, are so Protean and so numerous, that it would be almost impossible to detail them; in fact, there is not a single nervous disorder which may not be simulated by the sympathetic irritation of worms. Epilepsy, hysteria, convulsions, dilatation of the pupil, amaurosis, symptoms of hydrocephalus, and even mania are among the affections of the nervous centres, or their immediate connexions, which, in repeated instances, have been found to depend on the presence of worms. Kraus gives an extraordinary case of a man, who, at a very advanced age, became subject from this cause to fits of continued and inordinate laughter.

There is another case on record of convulsions depending on worms, which, like those from the bite of the Tarantula, are said to have been soothed and relieved by music. Hufeland, in his journal, mentions a case of yellow vision from the same cause, and there are several instances of aphonia and mania on record, which have yielded to treatment which had removed intestinal worms. A case is

mentioned of a person who got violent spasmodic action of the muscles of the eye, producing inversion of that organ to such a degree, that the eyeball appeared to be nothing more than a mass of red flesh. A case is recorded by Serres, in which the symptoms strongly resemble those of hydrophobia, and it is probable that some of the cases of hydrophobia, said to have been treated successfully, were nothing more than this extraordinary irritation of the nervous system produced by worms. I saw myself a case, in which two eminent physicians made the diagnosis of hydrocephalus; it was that of a child, who was certainly to all appearance labouring under cerebral disease, for he had convulsions, coma, and dilated pupils. It was remarkable, however, in this case, that the treatment directed to the head, though early and well applied, proved totally inefficacious. A large dose of calomel was given, and some lumbrici passed; in the space of two or three hours there was an evident improvement, and the child quickly recovered.

During the course of practice I have met with several examples of affections of the respiratory organs, depending upon the irritation of worms. This affection has been long known. I recollect the case of a boy who was brought to me with an extraordinary affection of the chest. He was of a gross habit of body, of a flabby scrofulous appearance, and labouring under disease of the elbow-joint; but his chief complaint was, that he passed the night in great distress from incessant cough and wheezing. On examining the chest, I found the respiration healthy, and no other symptom of pulmonary derangement except a very slight bronchitic r le. On expressing my opinion of the case to the mother, she said that he was easy during the day, but that his condition was very different at night. To ascertain the truth, I took the child into the hospital, and found that her statement was substantially correct; for from four o'clock in the afternoon until next morning, he was in a state of perfect orthopnoea, with loud, ringing, incessant cough. During the rest of the day he was free from cough, and tolerably quiet. The case was treated with calomel and ipecacuanha, tartar emetic, and other similar remedies, but the disease was rather exasperated than improved. The boy had swelled belly and constipation, and for this he was ordered to take a dose of turpentine and castor oil. He passed some worms with relief to the existing symptoms, and from the consideration of this, and the failure of the treatment for bronchitis, we were determined to persevere in the use of anthelmintic medicines, and, for this purpose, put the child on syrup of cowhage, to be followed by castor oil draughts. He passed vast quantities of thread worms in the course of a few days, and when they had been all removed the cough disappeared altogether, but as long as any of them remained, the symptoms of pulmonary irritation continued. There could

be no doubt that this was a case of intermittent bronchial irritation from worms, for their evacuation was immediately followed by a complete cessation of cough and dyspnoea. I have also, since the foregoing, met with many other instances of a similar description. A young girl came into the Meath Hospital with chronic bronchitis and some degree of hepatisation at the lower part of the left lung. Having heard from her friends that she was extremely subject to worms, I determined to try what would result from the use of anthelmintic medicines, and put her on the syrup of cowhage with aloetic pills. Under this treatment the cough was quickly removed, and the lower portion of the lung recovered its permeability. Here, it was remarkable, that not only irritation of the bronchial mucous membrane, but even solidification of the lung, were cured by treatment calculated to remove worms. Mr. Ramsay, in his paper published in the *Medico-Chirurgical Transactions*, gives several cases of hæmoptysis from this cause. I think I have seen several cases of phthisis, where the original source of pulmonary irritation seemed to be the existence of intestinal worms.

Let me here, however, remind you, that we should be cautious in attributing too much to worms as the causes of morbid symptoms. There are several reasons why you should be on your guard in this respect, one of the most obvious of which is this,—it does not follow, in the first place, that the symptoms in any particular case are produced by worms, because the same cause, which may have predisposed to the formation of worms, may have produced the symptoms in question, and there may be merely a coincidence of worms and of these symptoms. Even if we look to the results of treatment there is a great deal of doubt and difficulty. There are many cases on record which are described as cases of epilepsy from worms, and where all the symptoms have subsided under the use of anthelmintic medicines. In many of these cases we find the medicine chiefly employed has been oil of turpentine, and I need not tell you, that this is an excellent remedy in many cases of epilepsy totally uncomplicated with worms. The results of such cases do not necessarily prove that worms were the source of irritation. Again, immense injury is frequently done to children in persisting in the anthelmintic treatment for the supposed existence of worms. Recollect, the prominent phenomena of worms in the intestines are irritations of the digestive system and of other functions. Now, it is very well known that these symptoms may occur with or without worms. If, then, you have a case where these phenomena are present without the co-existence of worms, and if, under a mistaken impression, you treat it with anthelmintic medicines, you inflict a double injury; you exasperate the original disease by the drastic and irritating medicines which are ordinarily used for the removal of worms, and you do an indirect injury by

neglecting to adopt proper means of treatment. There is nothing more common than to see children labouring under some irritation of the digestive tube, which is mistaken for worms, purged again and again until they get incurable enteritis or *tabes mesenterica*. When a child has foul tongue and breath, picking of the nose, diarrhoea, and turbid urine, it is a common notion that he is labouring under worms. If he gets feverish, it is said to be worm-fever, and the anthelmintic treatment is pursued with unabated vigour. Now, I believe that a great majority of such cases are in reality disease of the mucous surface of the intestine, and that the consequent feverishness is dependent on this state. Another reason why you should be cautious is this,—in persons of an hypochondriac habit, there is nothing more injurious than their getting the idea that they have a worm in their bowels. When once this notion gets into the head of an hypochondriac, it is generally impossible to eradicate it. Some of the most melancholy and fixed cases of hypochondriacism are produced in this way; every symptom is attributed to the worm, the patient is in a state of constant feverish anxiety about it, he talks of nothing else, and is constantly taking medicines to expel it, to the great detriment of his general health and with a manifest exacerbation of his symptoms. Medical men should be extremely cautious on this point. The patient is perhaps a female of hypochondriac and nervous habit; she has gnawing sensations about the epigastrium, which she supposes to depend upon the presence of a worm, and an injudicious practitioner favours the notion. He gives her various medicines to expel the worm; no worm is passed; she becomes more anxious, takes more medicine, and gets weak and emaciated. She then begins to think that all the nutritious matter in her body is going to support the worm, falls into a desponding state, and continues for the rest of her life an incurable hypochondriac.

We come now to consider the exciting causes of worms. On this subject I believe our knowledge is very scanty and inaccurate. The following, however, are generally looked upon as remote causes:—foul air, residence in damp and unhealthy situations, sedentary habits, and want of wholesome exercise, over-feeding, the constant use of certain articles of diet, as farinaceous substances, milk, cheese, sugar, &c. An eminent authority (Bremser) asserts, as I have already stated, that unabsorbed chyle in the digestive tube constitutes the most fertile source of worms. It is a common idea, that poor diet has a strong tendency to give rise to the formation of these animals, but it has been frequently observed that worms are met with in persons who are by no means in want of nourishment; and it is said that in cases where nutrition has been diminished in man and other animals the worms die. If this be the case, it would

appear that, so far from being the exciting causes of worms, poor diet rather tends to favour their removal. Uncooked vegetables and fruits are also reckoned among the causes of worms, but I believe this arises from the mistaken notion that the ova of intestinal worms occur in vegetables, and, being taken with them into the stomach, are there developed, or even changed in their organisation, a position which we have already proved to have no foundation in truth. Persons who live principally on vegetable food have not been observed to labour under worms in a comparatively greater degree than those who use an animal diet. It is said that the Swiss, who consume a great deal of vegetables, are very subject to worms, but other nations who live in a similar way have not been remarkable for the same liability.

Worms have been stated to be occasionally epidemic. It is not very easy to determine this point, but it has been remarked, that at particular periods these animals have been more than usually frequent and numerous. Many authors have described an epidemic of what has been called *verminous fever*, that is to say, fever of a gastric or bilious character accompanied by worms in quantity. It is hard to say what the nature of this fever really was, and whether it might or might not be fever with irritation of the digestive apparatus, one of the consequences of which was a discharge of worms already existing. That worms are endemic, is a proposition very easily conceived, for we see it illustrated by the extraordinary prevalence of these animals in sheep which are kept in low, damp pastures. In such situations worms are met with in great abundance in the liver and other parts of these animals.

It would appear from the following remarkable case, detailed by Bremser, that the use of milk and farinaceous food predisposes to the formation of intestinal worms. This gentleman, who was physician to a monastery, and had ample opportunity of studying the habits of its inmates, was called to visit one of the oldest of the monks, who was said to be labouring under great derangement of the digestive system. On inquiry, he found that the patient had lived for sixty years in excellent health, using animal food, which, however, he had been latterly induced to change for farinaceous diet and milk. For a few days this agreed tolerably well with him, and then he began to be tormented with colicky pains, flatulence, sour eructations, and other distressing symptoms. His physician gave him some purgative medicine, and he passed a large quantity of tape-worm with relief; the treatment was persevered in, his former mode of living resumed, and he recovered quickly. This case bears strongly against the fanciful hypothesis that the ova of worms are transmitted in the act of generation; for how could it be possible that the ovum of this tape-worm, transmitted in this manner, could re-

main undeveloped in the system for the space of sixty years? This case derives additional interest from the fact of a change to a farinaceous diet being apparently connected with the formation of worms.

Another remarkable case is given by the same author. The patient was a married female who had twelve children,—six boys and six girls. This woman observed, that, whenever she was pregnant of a girl, she had a great longing for milk and farinaceous food, and lived on these articles of diet almost exclusively. After living in this way for some time, she uniformly got an attack of worms, and this, as well as the longing for vegetables, coincided with the birth of a female child so invariably, that she was able to tell with certainty whether the child she carried was a male or a female. This is a singular and well authenticated fact.

We come now to the treatment of worms. Generally speaking, this is extremely simple, the principles of treatment in the various kinds of intestinal worms being nearly the same. Simple as they are, however, some persons entertain false notions respecting them. They appear to think that all they have to do is to evacuate the worms; and, having accomplished this, they rest satisfied and take no steps to prevent their recurrence. But the mere evacuation of worms is no proof of a cure; to effect this you must prevent their return. From what you have learned with respect to their exciting causes, you will be able to give such directions as to the patient's mode of living as will obviate their recurrence; and, with regard to the means to be adopted for removing them, we may divide them into the following:—We have, in the first place, what is called the mechanical treatment, next the specific, and, lastly, the purgative treatment. The first and last are nearly connected. For instance, purgatives appear to act in the same way as mechanical anthelmintics, by irritating the mucous surface of the intestine and the worm, and thus causing its dislodgment and expulsion.

Among the principal mechanical anthelmintics are filings of tin, cowhage, powdered charcoal, and crude mercury. Among the specific are a variety of substances, most of which have a strong and peculiar smell. This is a very curious fact. Valerian, assafoetida, camphor, ether, and other odorous substances have been found to be anthelmintic, and the *Geoffræa inermis*, which has been employed for this purpose, is remarkable for its strong unpleasant odour. The same thing may be said of tobacco, the oil of chenopodium or wormseed, garlic, artemisia absinthium, and many others. With respect to purgatives, there is not one in the whole list, particularly those of the drastic kind, which may not be looked upon as an anthelmintic.

It is the opinion of the most eminent men, that the thread-worm is the most difficult to expel, because they are generated with an ex-

traordinary rapidity, and accumulate in a very short space of time. You are satisfied of their existence, have seen them in the alvine discharges, and the patient has all the ordinary symptoms. Well, what is the best way of getting rid of them? You shall commence by the exhibition of a mercurial. It is difficult to explain why it is that mercury has such an effect in removing these worms, but the experience of the best practitioners can be adduced in proof of its efficacy. The statements of Dr. Latham of London, and of many practitioners in this country and on the continent, go to prove this. In whatever way it acts, mercury appears to be a powerful anthelmintic; and it is a fact that these worms have been expelled where it was given in very small doses, and not sufficient to operate as a purgative. The best plan is, first to give a mercurial purgative, and then to have recourse to the mechanical treatment, giving, with this view, the syrup of cowhage, one of the most efficacious of this class. It is a remedy which is easily managed, and will do no harm; for, though it produces violent itching when applied to the cutaneous surface, it produces very little sensible effect on the intestinal mucous membrane. The form which I employ is the following:—Take of the hairs of the *dolichos pruriens* one scruple, syrup of orange-peel an ounce; of this an electuary or syrup is to be made, of which you may give a child a teaspoonful three times a-day. This is the remedy on which the West Indian practitioners, who have frequently to treat this affection in the negroes, place the greatest reliance; and you will find that if you employ it a vast number of worms will be often passed. It should be continued for two or three days, and then a purgative must be given, after the operation of which it may be again resumed, if necessary. An excellent adjuvant to this is the use of aloetic injections, composed of two parts of milk and one of the decoction of aloes. In this way, you will be able to remove a vast quantity of these little animals from the rectum. It has also been observed, that injections of cold fresh or salt water have a great power in promoting their expulsion. Bremser mentions that in cases where these worms pass from the rectum into the vagina in females, and excite irritation, there is nothing so effectual in destroying them as injections of cold water and vinegar. This you should bear in mind. You should also remember, in the case of administration of syrup of cowhage, to give strict orders not to let any of it drop on the child's skin, as it would excite a great deal of irritation. You should forewarn the attendants of its effects on the skin; and if any of it should be spilled on the hands, neck, or face, the best thing is to wipe and wash the part well, and then rub it with a little almond-oil.

For the expulsion of lumbrici there is nothing so successful as the ordinary purgative treatment. A bolus, composed of calomel,

rhubarb, and jalap, will answer this purpose extremely well; you may also use the syrup of cowhage with much advantage. Bremser gives a formula for an electuary, which I have not tried, but have no doubt of its value, for it appears to combine all the qualities of a good vermifuge electuary. It is made as follows: Take of the seeds of *santonium*, and of the flowers and leaves of tansy, reduced to powder, each half an ounce. Here you have two anthelmintics of the specific kind. Add to these two drachms of powdered valerian: here is another. You then combine with these two drachms of sulphate of potass and a drachm and a half of jalap: these are purgatives. You then make them up into an electuary with syrup of squill, which is also an anthelmintic of the specific kind. Of this electuary two or three teaspoonsful are to be taken during the course of a day. Bremser states, that this combination is of great value, particularly against lumbrici and tape-worm.

The treatment of tape-worm is not difficult. All the specific and mechanical anthelmintics are useful in promoting its expulsion, but there is nothing which appears to have such a powerful effect as full doses of turpentine and castor oil. This constitutes the best remedy we possess against the *tænia*; but if you wish to get rid of it entirely, you must give the turpentine in full doses. You will frequently be astonished at the vast quantities of this worm which will be passed. When you give turpentine, it is safer to order a full dose of it, for if it be given in small quantities it is very apt to irritate the urinary organs. Half an ounce of turpentine, with the same quantity of castor oil, form an efficacious though very disagreeable draught. You may, however, obviate its nauseousness by the addition of a small quantity of camphorated tincture of opium and mucilage of gum arabic. The celebrated empyreumatic oil of Chabert is, in my mind, nothing more than a modification of the turpentine. This is the remedy which Bremser looks upon as most efficacious against the tape-worm. You have all, I presume, heard of the animal oil of Dippel—the oil which is produced by the distillation of bones or hartshorn shavings. To one part of this are added three parts of turpentine: these are left to combine for four days and then distilled; the first three parts of oil which come over are called the empyreumatic oil of Chabert. It is an exceedingly nauseous remedy, has a most disgusting smell, and is seldom used in this country. Bremser recommends it to be taken in doses of a teaspoonful three times a-day. Some persons who have tried it have assured me that it is extremely difficult to be taken, and that it excites a train of most disagreeable abdominal sensations. Bremser, however, thinks highly of it; he is in the habit of directing his patients to take it for three or four successive days, then to omit for a day or two, and then to return to it again; and he says that it not only succeeds in evacuating the

worm, but also in preventing its return. In addition to this, he recommends the use of a fortifying tincture, which I think very useful in worm cases. It is a combination of one of the salts of iron with a preparation of aloes. If you take equal parts of the muriated tincture of iron and tincture of aloes you will have a remedy somewhat similar to the strengthening tincture of Bremser. Twenty drops of this mixture, taken three or four times a day, will prevent the recurrence of worms.

We shall not meet again, gentlemen, until after the Christmas holidays; our next lecture will be, therefore, on Wednesday week, when I shall take up the subject of painter's colic, and some other affections connected with the viscera of the abdomen, and then pass on to the consideration of thoracic diseases.

CLINICAL LECTURES

ON THE

SURGICAL ANATOMY AND TREATMENT OF
THE UTERUS AND ITS APPENDAGES.

BY M. LISFRANC,

PRINCIPAL SURGEON OF THE HOSPITAL OF
LA PITIE, PARIS.

(Translated by Mr. H. Rush, late Clinical
Clerk to Dr. Elliotson, at St. Thomas's
Hospital.)

LECTURE II.

*Diseases of the Uterus and its Appendages—
Disorders of the Menstrual Fluid con-
sidered as a Cause of Enlargement of this
Organ—Flooding or Metrorrhagia—Leu-
corrhœa—Hysteria—Treatment, &c., &c.*

GENTLEMEN,—In my first lecture I gave you an account of the two principal means of diagnosis in morbid alterations of the womb—the vaginal examination (*toucher*), and the speculum. Before I enter into a minute description of these alterations, I think it better to consider the influence which the irregularities of this organ have on its functional development, a study not less useful for the prophylactic than for the etiology, and which has not been sufficiently considered. I shall now speak of derangements of the menses—metrorrhagia, leucorrhœa, and accessions of hysteria, considered as the principal causes of diseased alterations of this organ. I will, at the same time, superficially glance over all points that I believe to be known on this subject, so that I may give you the practical conclusion of my own observations.

Disordered state of the Menses considered as the cause of Plethora of the Uterine Organ.

—This morbid sign should be arranged under four heads; the defects of menstruation and the symptoms which accompany it, either at its first approach, at its periodical returns, or at its natural cessation.

1st. *Absence of Menstruation.*—There are some women in whom the menses never ap-

pear. I have, within the last ten years, known fourteen cases of this kind, the modifications of which varied according to the temperaments of the individuals. But, at every return of the menstrual period, the patients became susceptible, irritated, and melancholy, frequently affected with headach, suffocations, a sense of weight about the pelvic organs, colic, &c., without ever having the slightest appearance of menstrual discharge. There are others, again, who never experience these periodical indispositions; but, in general, these are women who have very delicate health, are more or less emaciated, tissue lax, flaccid, and colourless; their sallow hue announcing the affliction; and sometimes they are harassed with colicky pains and diarrhœa, sometimes with palpitations, headach, &c.

What must we do, then, under these circumstances? Some practitioners attribute these phenomena to the organisation of the woman and to her sedentary habits; others regard the absence of this fluid to be the principal cause they have to encounter, and try every remedy they can think of to reproduce its discharge, which, in general, does more harm than good, by attracting the blood into the pelvic cavity, and thus augmenting the congested state of the uterus, causing an increase of the symptoms, which frequently continue even from one menstrual epoch to the other, without the least intermission. Above all things (for it is of the greatest importance) you must become acquainted with the cause that impedes its establishment. You will frequently find, by vaginal examination, an engorgement of this organ, which it is necessary to combat. In two instances I have succeeded in subduing this plethora, and establishing a regular menstrual period, in one of which the female has since become a mother. If this cause does not exist, and if many years have elapsed without the catamenia, they are, in general, definitely lost, and it is useless to meditate their reproduction. Would a practitioner, then, abandon such women with their sufferings? Certainly not; but assist nature, by establishing some artificial sanguine evacuation. Thus, when return of pains predicts the menstrual period, it is necessary to take blood from the arm to the extent of four or five ounces, or, what is still better, to apply four or five leeches to the arm, and allow them to bleed moderately; at the same time have recourse to tepid baths, moderate exercise, and mild liquid diets adapted to the constitution. Thus, to weak and nervous women we should allow a nourishing and tonic diet; but on the contrary in those, in whom the nervous susceptibility predominates to a remarkable degree, we should employ narcotics both by injection and friction.

When these pains, instead of returning at the menstrual period, are continual, the indication is the same. We endeavour to find out, after the subsidence of these symptoms, the correspondent period of menstruation, and if

we cannot, it is necessary to choose one, and, at each return of this menstrual period, to employ the practice I have pointed out. It will lessen the plethoric system; and this treatment must be persevered in for a long time—for months, and even sometimes many years, and then it is seldom that the pains are reduced, much less dispersed altogether.

This total non-appearance of the menses is allied to their periodical suppression, when it continues for a time more or less considerable. I have seen some women who have only menstruated once in every fourth or sixth month, and even only every third, fourth, or sixth year, suffering sometimes continually. The indication is then the same as for those who have never menstruated; at other times they enjoy apparently perfect health. It is, however, to be feared, that this deceitful calm serves only to disguise some more serious disease that will make its appearance at a later period—such as disease of the heart, latent peritonitis, or some chronic pulmonary affection. I knew three young women who never became pregnant, and who menstruated only at protracted periods. They are now all dead: one died at the age of 21, from aneurism of the heart; the other two, one at the age of 19, the other at 24, from tubercular pulmonary phthisis; consequently I think it necessary to take, from time to time, small quantities of blood from the arm, and prescribe an appropriate diet. I have adopted this plan in a woman 36 years of age, who for the last six years has not menstruated, and is going on well under this precaution.

2nd. The first appearance of menstruation.

—It is generally believed, that, before the epoch at which menstruation ordinarily commences, the uterus is exempt from all morbid alterations, an error which it is very important to abolish. M. Carron du Villards has related a case of polypus situated in the cavity of the uterus, with engorgement of this organ, in a child seven years of age. There are a number of women advanced in age, who can trace back the commencement of the symptoms to their infancy. Again; I was consulted by a lady, whose health before the period of puberty began to decline; she complained of pains in the loins, a constant sense of weight, accompanied with pains, within the pelvis,—suspected to have been gastro-enteritis. I feared the cause, on the contrary, was very different. I examined the womb, which revealed to me at once a sub-inflammatory engorgement of this organ; I treated it accordingly, the patient soon became much better, and is now looking forward to a perfect recovery.

Theory alone could have induced us to presume that which the facts in this case have confirmed. The menses do not make their appearance all at once; the blood flows for a long time previously towards the uterine organ. If it encounters any obstacle to its return (and we know what difficulties this evacuation ex-

periences in establishing itself), this monthly determination towards the uterus—will it not occasionally terminate in engorgement of this viscus? It is to this cause we must attribute the lumbar pains, the sense of weight within the pelvis, of which young girls complain under these circumstances, and subsequently paleness, oedema of the lower extremities, want of appetite, weakness, sensations of suffocation with palpitations, which medical men frequently consider to be aneurism, and even sometimes a thing still more vague, *disease of the heart*. Besides, what renders the diagnosis more obscure is, that at the commencement of the affection the patient suffers less than at a more advanced period, and mistaken modesty prevents her, especially at that age, to express clearly all the symptoms she experiences.

You can perceive, then, from what I have said, how important it is, for the prevention of uterine affections, to establish, if possible, menstruation in girls arrived at the age of puberty. I do not speak of those who are healthful and strong, for in them nature is sufficient to produce the new functional formation of this organ. But should the girl be in a delicate state of health at the commencement of this epoch; it is necessary to allow her a very nourishing diet, give her slight tonics, use cold and aromatic baths, combined with exercise in the open air on a sunny day, these are powerful auxiliaries. It is in these cases, especially, that we can employ with advantage local remedies, such as foot-baths impregnated with the flour of mustard, or else with a decoction of mugwort or wormwood; glysters of a warm temperature, and like injections for the vagina; emollient local baths, warm cataplasms applied around the pelvis and to the vulva; dry cupping, frequent blisters, the application of a few leeches to the ankles, legs, or superior and internal part of the thighs, but seldom or never to the vulva; small bleedings from the feet, &c. As regards the foot-baths, I should recommend them to be made with a sufficient quantity of water, to allow the legs of the patient to be immersed as far as the knees, for when the feet only are covered, they are more frequently injurious than useful.

If, on the contrary, symptoms of uterine congestion manifest themselves in a young woman, whose appearance indicates a strong constitution, these topical remedies will only augment them. It is necessary, then, in such a case to have recourse to warm and frequent baths, a vegetable diet, and that sparingly, moderate exercise without fatigue, and, lastly, to take small quantities of blood from the arm, to the extent of one or two pallets, (a pallet contains about eight ounces).

A cause, which frequently prevents the establishment of the menstruation, is masturbation; besides the preventive means in these cases usually adopted, it is essential to calm the physical disposition of the patient, by removing every cause of excitation, and to appease the existing irritation by the administra-

tion of narcotics, and these principally by the rectum.

Whatever should be the remedies we think of exhibiting in this disease, it is essential to employ them only at the conjectur epoch, or twenty-four hours before it, in the intervals of which we must confine ourselves to general palliatives.

The choice of local means is far from being indifferent. Nothing is more fantastical, and, if I may be allowed the expression, capricious than the menstrual function; we find it excited by foot-baths in some women, again in others we find them suppress it. The application of warmth, exercise, either on horse-back or in a carriage, and a multitude of other remedies will at times be beneficial, depending on the different states of the individuals, as to the effect these produce, for neither temperament nor constitution has any thing to do with it. There is in every female a peculiar idiosyncrasy, adapted to the performance of this function, which it is necessary to examine and regard with cautiousness in those women who have already menstruated; and in those who have not yet experienced this, the medical man must still be more reserved as to the remedies he employs.

3rd. Difficult menstruation.—When the menses have once been regularly established, they are not always exempt from irregularity. There are many women, who signalise the periodical return by insufferable pains, which come on some hours previous to, and continue some hours after, the menstrual appearance, sometimes, however, only during the period of the discharge; but, again, they sometimes will continue two or three days after its termination. Almost always these menstrual pains are hereditary, and, by questioning those women, who labour under this affection, they will in general tell you, that there have been many in the family who have suffered previously in the same way, and have died from disease of the uterine organ. This circumstance, then, requires some serious attention; we easily can conceive that the uterus, which has been the seat of similar congestion, at monthly intervals, for the space of 20 or 30 years, is more predisposed than another to consecutive alterations; and I have had occasion to witness this fact in numerous instances. If, during the interval of menstruation, by vaginal examination, we explore these parts, we find the neck, but more frequently the body, of the uterus engorged, increased in volume, and the seat of sub-inflammation; if the disease has already extended thus far, above all things it is necessary to subdue it on the principles I will name to you by and by.

If, on the contrary, we find the uterus healthy the woman must not be abandoned to her sufferings, according to the doctrines of those practitioners, who imagine it to be the effect of a peculiar natural idiosyncrasy of the constitution. It is certainly difficult to obtain a cure, but the least we can always do is to

render some alleviation. The object of our study here must be principally the constitution, not only for vague speculation, but in order to guide us in our treatment for its modification.

These pains, in the majority of cases, are purely nervous, indicated by the globus hystericus, the patient experiences spasms, and strong voluptual desires, but the coitus, far from being agreeable, excites and irritates the nerves; if an injection be thrown up the vagina, it is immediately expelled, the pulse is small, contracted, and vibrating; there is subsultus tendinum, and the whole frame starts at the slightest emotion. Two or three days, then, before the menstrual epoch, we must endeavour, if possible, to lessen this nervous state of irritability by the use of narcotics, and especially by the administration of the tincture of opium in small quantities by injection, and it is necessary to follow this up during the menstrual intervals. Should the patient be purely nervous, cold-baths, warm injections by the rectum, and narcotics sometimes prove beneficial, but at other times they are injurious. On which account we should carefully examine the idiosyncrasy of every patient. In lymphatic females, who have a delicate and flaccid skin, we should prescribe bitter tonics, cold baths, good nourishment, some narcotics, and, if required during menstruation, small bleedings. In plethoric women, on the contrary, the preference should be given to warm-baths, and the patient allowed to remain in them for some time, a vegetable diet, reduced to a fourth, or even by degrees to two-thirds of the accustomed quantity, very moderate exercise, emollient liquids, which may be taken bountifully, but an entire exclusion from coffee and spirituous liquors are necessary; lastly, 24 or 48 hours after the menses appear, we should take blood from the arm to the extent of a pallet, and repeat it in fifteen days if necessary.

The menses once commenced nothing more is required than to encourage their discharge. But it will sometimes happen, after a few hours, or a day subsequent to their appearance, they suddenly cease, although they may have been accustomed to continue for a much longer period; should the uterus be healthy, it is necessary to re-produce them, if possible, in 24 or 48 hours after their disappearance; but if this organ be diseased other means must be pursued, for when I have attempted to solicit their return in these cases, nineteen times out of twenty, my attempts have failed, and at the same time have greatly increased the sufferings of the patients, so that I always now leave them to the effect of nature; merely take a small quantity of blood from the arm, which I repeat in the course of five days, and prescribe, according to the temperament of the individual, the emollient or tonic decoction.

At other times affections of this organ do not so suddenly check this discharge but allow it pass off only in very small quantities,

Should we then in such a case endeavour to favour the flow of this secretion? in many I have with success, but again in others, in attempting this, I have increased the congestion. There are as many arguments for as against this hypothesis, neither have I come to a determination to which I should give the preference. Nevertheless, should they be completely arrested, there are good reasons why we should not endeavour to reproduce them. On the one hand, most probably the means we employ would be useless, while, on the other hand, they may produce serious consequences, by adding greatly to the congestion.

Again, sometimes we have an immoderate discharge of this secretion. I have stated that corpulent women have ordinarily a very scanty flow; whilst, on the contrary, it is more abundant in the meagre, who can be tracked, as it were, during the two first days; since, in spite of all their customary precautions, the blood escapes, and they are obliged to stay in bed, and exist for some time afterwards in a state of great debility. Baths, when in a state of health, moderate exercise, and a scanty vegetable diet, are the best means to moderate this excessive discharge; but should the patient be feeble and nervous, a generous diet is then necessary, with narcotics. In neither case it is not necessary to omit small bleedings from the arm, and repeat them during the intervals of menstruation if there be need.

4th. *Cessation of the Menses.*—The time at which the cessation of the menses takes place is generally between the age of forty and fifty; these cyphers are said to represent the two extremes. I have seen many cases in which it has terminated at the age of thirty-five. I know a woman, aged forty-two, who has been exempt altogether from this sanguine discharge since the age of fourteen; and at the present time I have three patients, one 54, the other 56, and the third 64, who are still menstruating, these being of an ordinary temperament, and enjoying perfect health.

In the majority of females the menstrual cessation is announced many months, or even many years previously, by some derangement in the secretion, it being sometimes more, at other times less abundant, or returns only at irregular periods. The uterus modifies itself by degrees, till at length it does not any longer admit a free exit to this discharge, still, however, for some time, the blood every month flows as customary to the uterine organs, constituting one of the principal causes of congestion. Nevertheless you must not imagine, though it is generally stated so in medical schools, that diseases of this organ more frequently take place at this epoch than at another. This great axiom in physiology, which holds good here as in other parts, the more an organ is exercised, the more liable it is to disease, and it is from the twenty-fifth to the thirty-fifth year that the sexual organs are most employed, and also it is between these

periods that their diseases are most frequent. We have in this hospital, in St. Augustin Ward, a great number of affections of the uterus, and amongst them who are thus attacked, you will not find three that have attained the age of forty.

Nevertheless, in some women, affections caused by uterine congestion commence at the epoch termed critical. In many instances, the venereal orgasm is experienced for the first time with violence, and in these cases nineteen times in twenty, the irritation of the womb must be considered as the cause, as in the same manner the most distant irritation of the bladder in the male produces frequent erections. Hence also the pains, indeterminate flushes, nervous affections, headaches, palpitations, leucorrhœa, and frequent floodings; these symptoms declare themselves more especially in large towns. In the country, women are engaged in laborious occupations, and lose, in the perspiration induced by toil, the fluids they no longer evacuate by menstruation.

When symptoms of this description appear, we must subdue them without delay, in following the principles already explained. We must not endeavour, therefore, to increase the scanty discharge, by determining the blood towards the uterus, thereby certain of producing congestion of this organ, but in one or two days after its cessation, we must supply its place by small bleedings from the arm. The pains it is necessary to combat by baths, narcotic glysters, and emollient injections. If the women be the prey of excessive venereal desires, it is to be borne in mind, that this orgasm, produced in the first instance by irritation, might afterwards contribute to its increase; it is necessary, therefore, that they avoid with care a perfect abstinence, as well as an excessive abuse; coition in moderation may then be permitted with advantage. Lastly, if the discharge assumes the character of flooding, recourse must be had to the means pointed out against this accident.

Metrorrhagia, or Flooding.—I must first beg you to bear in mind that it is my intention to speak of floodings, as being either the cause or effect of the affections of the uterus. I shall omit the description of floodings produced by pregnancy and parturition, as belonging to the province of the accoucheur.

Flooding may appear in females who have still their monthly courses, also in those in whom this discharge has ceased to exist; this latter is very common, thus five, ten, fifteen years after the critical epoch, old women even are sometimes seized with a sudden metrorrhagia, and they consequently imagine that their menses have returned. It is therefore necessary not to confound these attacks of metrorrhagia with a copious menstrual discharge; true flooding has not the periodical regularity which distinguishes the menstrual flux. Thus when one appears which lasts fifteen days, perhaps more or less, shortly

afterwards it disappears spontaneously, either for ever, or may return at indefinite periods. Sometimes the menses will make their appearance first, last one or two days, and the flooding commences the following morning, continues about ten days, and will of itself cease in twenty-four hours, but soon afterwards return again; at other times the flooding precedes the menses, stops for a short time, and afterwards allows them to continue their accustomed course.

When the floodings are abundant, and continue for many years, it becomes constitutional, and it would be imprudent to endeavour to check it all at once, for there would be cause to fear the appearance of serious symptoms manifesting themselves in other organs, and principally the lungs, whose sympathies are so intimately connected with the genital organs. The practitioner should direct his attention more particularly to this region, after the cure of a metrorrhagia of long standing. At the commencement of these symptoms, it is necessary to lessen speedily the sanguineous system, and form a seton at the internal part of the thigh; should the symptoms be intense, one on each thigh may be applied with advantage, to replace the seat of the irritation which existed in the pelvis.

A woman living in the Rue Saint Louis, aged 28, never having borne children, for the last twelve years suffered from a flooding, which always appeared previous to the menses. The first time that I attempted to suppress it, peritonitis supervened; on the second, in spite of reducing the sanguineous system by blood-letting, peripneumonia declared itself, and the third time a meningitis. These symptoms always yield, as if by enchantment, on the application of leeches to the vulva. Another female in the Rue St. Martin has for the last six years experienced a similar flooding, which was kept up by an engorgement of the uterus; one bleeding from the arm suppressed the discharge, but headach combined with other unpleasant symptoms supervened, and was only relieved by a return of the flooding.

A young female in the Rue Grillon, having tubercles in the lungs, was subject to abundant flooding; I was particularly careful in not suppressing it entirely, endeavouring only to moderate the discharge, but as soon as the chest threatened to become affected in an increased degree, I endeavoured to re-excite the blood towards the uterus. By these simple means I prolonged the existence of her life for three years, the phthisis during the time remaining stationary. She went afterwards into the country; the medical man, to whose care she was confided, hastened to arrest the uterine hæmorrhage, to which he attributed her weakness, and a few months afterwards she was conducted to the tomb.

Is uterine hæmorrhage essentially a disease, as a great number of medical men imagine? For a long time since I have been in the habit of stating in my lectures that metrorrhagia is

to the womb that which hæmoptysis is to the lungs; and since the latter symptom exists rarely without organic alteration of the pulmonary tissue, so in like manner uterine hæmorrhage of long duration indicates almost always an organic alteration of the uterus. I do not intend to say that this is always the case, since in medical science there is no rule without exception, but I have not found the contrary in the immense number of females I have had occasion to examine. That metrorrhagia exists without local alteration, is possible, and I do not deny it, but I must declare I have not witnessed a single example. The causes of metrorrhagia are various; sometimes it will result from the presence of polypi, of which I shall speak hereafter, at other times from a slight or serious inflammation of the body or neck of the uterus, or from more or less extensive excoriations of these parts, which escape notice by exploration of the finger, and are not discovered without the introduction of the speculum, also from a vaginal inflammation; or, lastly, from every cause of irritation seated within the pelvis, which determines the blood towards the viscera of this cavity. Uterine hæmorrhage, treated as a symptom, may be momentarily arrested by local application; but to put an end to it entirely, it is necessary to discover and remove the exciting cause.

After what has been said, then, the practitioner perceives three distinct causes which must modify his treatment in uterine hæmorrhagia. The principal affection is either curable, and the flooding can be arrested without danger, or else the flooding is combined with some serious disease of another organ, which its suppression would inevitably aggravate; or, finally, it depends on an incurable affection of the uterus itself. I will now treat on this subject successively under three heads.

1st. We have already seen that sudden suppression of a metrorrhagia may produce serious consequences, though not any organic affection may be perceived in the patient. It is therefore necessary to adopt preparatory measures, even when the flooding is not comparatively of long standing; thus we should commence by a general bleeding, at most to the extent of one or two pallels. Bosquillon never omitted this precaution, even when the patient, had pallid lips small pulse, and appeared bloodless: and frequently you find the strength of the patient revigorate instead of diminish under its influence; the woman at the same time should be kept in a state of quietude, and allowed to drink either of the decoction or syrup of great comfrey; the next morning the bleeding should be repeated, if the patient's strength can bear it; after these two bleedings we may have recourse to local means, such as astringent and refrigerant lotions: the pelvis should be raised, and as a last resort, if the hæmorrhage be considerable, the vagina plugged with lint,

one of the most certain means of suppressing its flow. When at length the hæmorrhage is checked, the exciting cause must be treated, for a cure of the latter prevents to a certainty a return of the former.

The indications are the same when the flooding is of long duration, and has become constitutional, but preparatory measures in this case should be adopted a long time previous, in order to prepare the system to dispense with by degrees this unnatural evacuation. We must endeavour for months to modify the constitution of the patient; we must bring into use every hygienic resource, exercise, diet, sometimes tonic and substantial, at others vegetable and scanty, depending on the state and constitution of the patient; drinks, sometimes emollient and sometimes astringent, and particularly from time to time general bleedings: by the aid of such general means, the hæmorrhage will diminish by degrees, first, in intensity, and afterwards in frequency, and we shall then arrive at the possibility of arresting it altogether without danger.

2ndly. If when there is flooding there exists some organic affection, the same means may be employed; moderate the abundance of discharge, by the general rule indicated, but carefully avoid local remedies that would suppress it all at once.

3rdly. There remains to be described those cases, where the flooding is combined with an incurable affection of the uterus. Hence, in the majority of cases, the hæmorrhage, unless it be excessive, becomes beneficial to the patient, by diminishing the engorgement and mitigating the excruciating pains. If it be arrested either spontaneously or artificially the pains remain tormenting, and every symptom becomes aggravated. The disorganisation, heretofore slight, goes on with such frightful rapidity, evidently pointing out the necessity of caution. The hæmorrhage frequently increases the sufferings, constituting then a sign of increased plethora, which must be reduced by general means, especially by revulsive bleedings.

I have only as yet described hæmorrhages, whose abundance, though considerable, nevertheless does not proceed to such an extent as to threaten the life of the individual. If, however, the hæmorrhage declares itself formidable, doubtless every other consideration ought to yield before the urgent necessity of warding off the impending danger. In addition to revulsive bleeding, we should then have recourse to most active local remedies, such as cold and astringent injections, or have recourse to the plugging of the vagina without delay.

I shall not here enter into a lengthened description of this operation, but merely point out its most important points.

If the vagina is free, it is necessary to plug it only to the extent of an inch; on the contrary, if it be filled by morbid growths,

we must make compression on the vulva by the hand, or apply appropriate bandages.

The chief object of these precautions is not to irritate by these means either the diseased tissue or uterine neck, which we know acquire a sensibility in proportion as they become diseased; we also well know the influence of foreign bodies, when in contact with the uterus, in the production of these floodings. The clot, which forms itself between the apparatus and the uterine neck, will serve as a plug much less irritating. When the case requires the hæmorrhage to be moderated, but not suddenly and entirely checked, the dressings should be removed at the expiration of one or two hours.

Leucorrhœa.—White as well as red discharges have also been frequently considered as essential diseases. They may without doubt proceed solely from the vagina, and propagated in this canal may extend to the uterus, constituting a *utero-vaginal deflexion*; but at the expiration of a time, more or less—sometimes very short, the catarrh, which at first was the principal affection, becomes a secondary symptom, frequently also follows a contrary state, commencing by an engorgement of the uterine neck.

The discharge, which commences by an inflammation of the mucous membrane of the vagina, does not always, after its cessation, leave this tissue in the same condition. At its commencement there is only simple injection of the vessels, with more or less swelling; at a later period supervene infiltration, induration, ulcerations of the vagina and neck (an observation which has been thought new, though published thirty years since by Viguerie); and, lastly, vegetations. Therefore, you must readily conceive the importance of examining with care the vagina, the neck, and body of the uterus in cases of leucorrhœa, and the essential modifications which the treatment ought to undergo.

I shall not repeat that which may be found in every work on the causes of white discharges; I shall therefore only mention, that I have frequently seen them produced by foot-stoves (*chaufferettes*), and by coffee, which frequently produces their immediate reappearance in some females.

It is well known that a slight white discharge frequently appears the second or third day after the menstrual epoch. I met with a very curious and rare case, that occurred in a woman labouring under an engorgement of the uterus. Five, ten, fifteen, or twenty days after menstruating, certain symptoms declared themselves, as if they were about to return; shortly afterwards, she would suffer from a serous discharge, which would flow in such abundance, as to require napkins to the part, and so acrid as to irritate the external labia and the skin of the internal and superior region of the thighs, as to cause smarting and lacerating pains, and at the expiration of two days entirely disappear, but leave a slight

sensation of weight within the pelvis. Is this a case that was originally designated dropsy of the uterus? At different periods I examined the uterus, both per vaginam, per rectum, et per hypogastrium, without ever ascertaining an increase of its volume, putting aside its engorgement. Lastly, in order to ascertain more correctly the presence of a collection of fluid in its interior, I introduced an elastic gum catheter into the cavity of this organ, without ever detecting any thing in it. This serous flux is then the production of a sudden exhalation from its internal surface.

Leucorrhœa.—Is it or is it not contagious?—Is it or is it not venereal? Questions difficult to be resolved, and on which medical men still differ in opinion. I believe that leucorrhœa may communicate a venereal disease, and still more so when it is accompanied with slight ulcerations of the vagina or urethra; they more frequently occur than is imagined, since their existence can only be ascertained by the aid of a magnifying glass.

I will now proceed to the treatment of this affection.—When the discharge is recent, and is induced by an acute inflammation, recourse must be had to antiphlogistics, mucilaginous beverage, vegetable diet, and a bleeding more or less copious in proportion to the abundance of the menses. I never apply leeches to the vicinity of the pelvis in any acute disease, except in peritonitis: tepid and emollient injections into the vagina should be subjoined, and care taken to elevate this region, so as to allow them to be continued for some time, forming a sort of bath. When the inflammatory symptoms are calmed, counter-irritants may be given, such as bals. copaiba, or cubeba, in order to complete the cure, which is generally effected in a few days.

If the discharge be chronic, counter-irritants will still succeed in arresting it, especially if there does not exist an alteration of tissue, which of course would tend to keep up the disease; if the mucous membrane be indurated, we should apply by friction some of the ointment of the hydriodate of potash combined with mercurial in equal proportions, both on the hypogastrium and superior and internal part of the thighs. A piece of lint, besmeared with mercurial ointment, may be introduced into the vagina, if the female can bear its presence; and, lastly, recourse should be had to injections of various compositions.

During a long time surgeons feared the introduction of injections into the cavity of the uterus, when this organ participated in the catarrh: nevertheless, Hippocrates did not hesitate to give this advice; and Viguerie, at the termination of the last century, reproduced this practice.

It is necessary, however, to adopt certain precautions, such as to inject, in the first place, cold water only, having recourse afterwards to astringent decoctions or solutions, the strength of which may gradually be increased by a few drops of some concentrated

acid. A hollow gum catheter, introduced with care, will answer for the injection of the required fluid into this cavity. By this means you may frequently succeed in subduing discharges refractory to all other remedies. They frequently suppress the discharge at its onset, in the same manner as in man, or else act more slowly, requiring twenty or thirty days before they manifest their benefit; sometimes, however, they will alter inflammation from its chronic to its active stage. The treatment must be therefore modified according to circumstances, twenty or thirty days being necessary for its complete cure in both instances. If the discharge be kept up by chronic ulcerations, vegetations, or engorgement of the uterus, it is only by removing these causes that you can eradicate the discharge.

Nevertheless, in two particular instances, it is necessary to proceed with the greatest caution. When the leucorrhœa is of long duration it becomes habitual, consequently constitutional. Sometimes it is impossible, and even imprudent to attempt, to check it, especially if the patient be debilitated, and has at the same time a tendency to scrofula, and still more so if advanced in age. In other cases it is necessary previously to substitute another discharge in its place.

The intermittent discharges require also the same precautions as flooding for their suppression. It is unnecessary for me to repeat again what has been already stated on this subject; nevertheless, in studying attentively the temperament, if it be found that these discharges have followed the suppression of some habitual evacuation, or the repression of some exanthemata it is possible to obtain a cure, without inconvenience to the general health, by establishing an artificial drain.

6th. Hysteria.—According to the opinion of many medical men, hysteria is considered only as a nervous affection, and consequently does not come under the consideration of the surgeon; but experience belies this too exclusive idea; for if, sometimes, the disease be nervous, it more frequently results from a slight irritation or inflammation of the uterus. I have frequently been called to attend hysterical females, in the greater number of whom the uterus has appeared to me on examination to be endowed with great sensibility, and in a state of turgescence, accompanied with hypertrophy, the neck having the form and dimensions which it presents when two months advanced in pregnancy. In some instances the slight inflammation of the womb, which I have just indicated, has been clearly demonstrated by the autopsies. Hence the antiphlogistic treatment is necessary; thus, after general bleeding, I am in the habit of prescribing baths, emollient injections, and narcotic glysters: when these means fail, I slightly cauterise the abdomen. At the time we were blockaded in Metz, in the year 1813, a young female had every two or three days fits of hysteria, which resisted all anti-

464 *Case of Gelatiniform Softening, with Perforation of the Stomach.*

phlogistic means and yielded to cauterisation; besides it is well known that hysteria sometimes follows the abuse of, as well as the privation of, coitus. These exciting causes deserve great attention; as a general rule it is extremely important to pursue the treatment with perseverance one month, or even more if required; should, in these cases, the patient be obstinate you must be obstinate also, and success will be your frequent reward.

A CASE OF GELATINIFORM SOFTENING WITH PERFORATION OF THE STOMACH.

BY ANDREW BLAKE, M.D.,

Physician to the Nottingham General Lunatic Asylum, and author of a Treatise on Delirium Tremens.

Miss —, aged 19 years, of a robust make though of a pale and waxen complexion, was suddenly attacked on the 25th of last December with severe pain in the region of the stomach, accompanied with nausea and vomiting. I was requested to see her at 9 o'clock on the same night, and, on enquiry, I found that she had suffered for more than eighteen months from severe fits of gastrodynia, which generally terminated in vomiting; the frequency of these attacks appeared to depend very much on her mode of living, and the regularity of the bowels, the latter required constant attention, as when constipation obtained the fits returned perhaps twice a-week, but, by the observance of proper precautions, she sometimes passed a fortnight and even a month without experiencing one, and when living in the country they were still less frequent. It did not appear that fulness of the stomach had any effect in inducing them, as the pain often came on a short time before the hour of dinner.

On questioning the friends of the patients concerning the probable cause and nature of her then existing attack, they told me it commenced about 3 o'clock that day, immediately on having made an effort to prevent herself from falling back on a sofa, a person, who was sitting on it, having pulled her backwards, and that the moment she fell she complained of excruciating pain in the stomach, and called for warm brandy and water, from which she was in the habit of deriving relief on previous occasions, slight vomiting succeeded, but was not followed by any alleviation of pain; this circumstance, and the bowels having been con-

fined during the two preceding days, induced her sister to give her a solution of salts, which, however, had not the desired effect. On examination I found the abdomen painfully distended, tympanitic, and highly sensitive to the application of pressure. Constant acute pain was also experienced in the region of the stomach, which she described as extending from that viscus to the whole of the abdomen. The skin was hot; the pulse rapid and small; the countenance anxious to a degree; and the tongue morbidly red and dry, causing excessive thirst. The patient, at the same time, stated that, although the salts she had taken had not operated, she felt as if they were soon likely to have that effect.

Conceiving, from all the circumstances of the case, that no time ought to be lost in instituting active means for her relief, I immediately determined on abstraction of blood from the arm, together with the administration of emollient and laxative enemata, as well as the constant application of warm fomentations to the abdomen. The removal of about 22 ounces of blood induced slight syncope, and was followed by apparent relief, the pain having diminished very considerably, and the abdomen, although it continued tense and enlarged, bore pressure much better; therefore, as the disposition to vomit had ceased, the pain mitigated, and the patient felt a sensation as if the bowels were about to be relieved. I left her at eleven o'clock, with directions to persevere in the use of the enemata and fomentations, according to circumstances; I also directed that, as soon as the bowels had been freely acted upon, she should take calomel and opium regularly. Not having heard any thing from her during the night I entertained hopes of finding her still better at my morning visit, but my anticipations were not realised, she was materially worse; the abdomen had continued to enlarge, and the pain became more acute, accompanied with urgent and incessant thirst, the rapidity of the pulse had likewise returned, and the anxiety of the countenance had become more striking, and, although there had been no recurrence of vomiting, the bowels had not been satisfactorily relieved; in fact, the evacuations consisted of little more than the enemata. I ought also to state, that the blood which had been drawn exhibited no marks indicative of inflammation, either by the buffy

coat or the cupped appearance. These discouraging circumstances rendered it necessary to repeat to the friends of the patient my unfavourable opinion as to the result of the case, after which I prescribed the immediate application of leeches to the abdomen, the repetition of the enemata, and the administration of calomel and opium, with effervescing medicines, together with the use of the warm bath. On my return, in the course of the day, I learned that none of the remedies had had the slightest effect in relieving the symptoms; on the contrary, the restlessness and pain continued to increase, and terminated in death about noon, scarcely 21 hours from the commencement of the fatal attack.

The rapid course of this case, without any satisfactory assignable cause, induced me to press on the friends of the deceased the propriety of permitting a post-mortem examination to be made, to which they at length consented; and Mr. G. M. White, surgeon of this town, having kindly offered his services on the occasion, we proceeded to the chamber where the body lay, accompanied by the brother of the deceased, a male friend of the family, and a medical pupil.

The inspection was made on the day following the fatal event. The abdomen appeared exceedingly tense and swollen, and a quantity of frothy fluid continually escaped from the nose and mouth. The body externally was unusually plump, and, on cutting through the parietes of the abdomen, the cellular texture contained at least an inch and a half of dense fat; when the peritoneum was punctured a vast volume of foetid air escaped, attended with a hissing noise, which continued for some seconds, and permitted the abdomen to collapse and resume its ordinary size. Having exposed the abdominal viscera, our first attention was naturally directed towards the stomach, as having been so long the seat of suffering; but, on a superficial glance, that organ presented nothing which struck us or induced us to apprehend that disease existed in its coats: it was natural in its colour, though undistended by air, while the intestines generally were inflated; we in consequence commenced our minute investigation by an examination of the whole of the intestinal tube; and although this was done with great care, we could not discover any trace of disease, save some slight

vascular injection of the colon; we had at first conceived, from some black matter, apparently vitiated bile, having attached itself to the inside of the ilium, and shown through its coats, that disease should be found in that intestine; we were, however, soon convinced this was not the fact. In examining the viscera of the pelvis, which were particularly healthy, we were surprised to detect a large quantity of yellowish whey-like fluid in that cavity, as well as in the lumbar regions of the abdomen, which, on further examination, was found to have issued from an aperture in the stomach; on returning to make a more minute investigation of the state of that organ, we perceived at its pyloric extremity several adhesions formed between it and the left margin of the liver, which, although they were not absolutely of recent formation, could not have been of long standing, and, on raising and throwing forward the stomach, so as to obtain a view of its posterior surface, which was done with great care, we were struck with the appearance of a round hole, about the size of a shilling, situated in its splenic portion, and presenting an appearance as if a piece had been cut out of it by means of a punch; the edges of this opening seemed exceedingly thin, but exhibited no traces of the ulcerative process. On removing the stomach from its situation, and laying it open, its internal coats, though not changed in colour, were attenuated in the greatest possible degree; and, in the vicinity of the opening already alluded to, the texture was so softened as to afford little more resistance to the fingers than an ordinary cobweb.

The liver was unusually small, but healthy in its parenchyma. The kidneys and spleen were natural, while the pancreas was nearly double its common size, though not apparently diseased in its structure.

Such were the principal phenomena which this post-mortem examination presented; and I have no doubt, were not similar occurrences to be found on record, the veracity of their details would be called in question, more particularly when compared with the acuteness of the symptoms which were displayed during the latter moments of life, together with the rapid termination of the complaint. I allude to the absence of almost all traces of active recent inflammation.

466 *Case of Gelatiniform Softening with Perforation of the Stomach.*

Andral mentions cases of this kind as having occurred in persons who were to all appearance but slightly indisposed, and who were only subject at intervals to pretty severe pains in the epigastrium, with rather difficult digestion, but who, in other respects, seemed in tolerable health at the moment they were suddenly attacked with all the symptoms of *acute peritonitis*, and died in less than twenty-four hours.

On examination after death in these cases, a sero-purulent effusion was found in the peritoneum, and near the middle of the body of the stomach was detected an ulcer of the breadth of a franc piece. I need make no comment on the similarity of such cases to the one which I have just related. M. Cruveilhier gives this disease the name of "*ramollissement gelatiforme*," or gelatiniform softening of the stomach or intestines, and remarks, that before touching their parietes one would often take them to be quite sound, as they may be modified only in respect to their consistence. This author also states having witnessed its prevalence epidemically amongst children at Limoges, and M. Sestier observed it in the hospital Des Enfants Trouvés, while Andral remarked it particularly in old people, in which latter case the appetite failed, there was a sensation of weight and uneasiness or pain at the stomach, the tongue became red, the strength declined, and all this was attended with extreme emaciation*, and terminated in death, without showing decided symptoms of a serious affection of any organ up to the last moments of life. On dissection nothing was found but more or less softening of the mucous membranes of the stomach, with or without injection of its tissues.

Dilatation of the veins, which run between the coats of the great extremity of the stomach, being visible is, by some, said to be indicative of the presence of this state, but we did not observe any such phenomenon.

Although cases of this nature, from the importance of the organs involved, appear to

be in almost every instance beyond the power of medicine, it would be at least satisfactory to be in possession of distinct diagnostic symptoms, by which we could distinguish this affection from pure inflammation of the abdominal contents, which it so nearly simulates, and I regret that I do not feel myself competent to solve this difficulty. Death, in the instance I have related, appears to me to have been induced by the excessive irritation consequent to the escape of air and fluid into the cavity of the peritoneum, by which such acute pain was caused, as was incompatible with the functions of the nervous system, on the same principle as death is sometimes the consequence of great operations or extensive burns, without having any visible traces of organic lesion sufficient to account for the event. It has also been a question, whether the perforation of the stomach or intestines takes place during life, or is produced after death by putrefaction, or by the solvent action of the gastric juice, as was the opinion of the celebrated John Hunter. The writings of Camerer and Baillard have thrown considerable light on this subject, and led me to venture the conclusion, that ramollissement and perforation are effected by the action of disease during life, and that even the latter may exist for some short time without giving exit to the contents of the stomach, provided the opening be kept in close contact with some other viscus, or part of the abdomen; but, as soon as this conservative arrangement of nature is interfered with by any sudden effort, such as that made by my patient in her endeavour to prevent her fall backwards, the contents of the stomach are at once forced into the cavity of the peritoneum, inducing that extreme pain and tympanitic distension which have been described.

The very short duration of the acute stage in the case forming the subject of this paper, not twenty-one hours, together with the consideration of the circular form of the opening in the stomach, as well as of the attenuated state of the coats in its immediate vicinity, all concur in warranting the conclusion that the perforation was not the effect of laceration, as it could not have assumed the round shape, and have manifested such loss of substance in the short space of time already mentioned.

Nottingham, April, 1834.

* This was the reverse in my case. Query, How could such a degree of obesity, as I have described, be compatible with so much disease of the principal assimilating organ of the body?

**OBSERVATIONS ON THE EFFECT OF
BARBADOES NAPHTHA, IN CASES
OF MORTIFICATION.**

BY DR. WILKINSON, OF BATH.

*To the Editors of the London Medical and
Surgical Journal.*

GENTLEMEN,—It is well known to professional gentlemen, that when any part of the animal body has from disease been deprived of its principle of vitality, or, in common words, in a state of mortification, there is always an effort exercised by the proximate living parts to liberate themselves of the mass deprived of its organic structure. Amongst many of the remedial means, charcoal in fine powder has been frequently employed in many instances with evident good effect, arising from its arresting, by its chemical agency, the decomposition of the substance with which it is in contact.

When mortification is extensive, it is then requisite that such a substance should be employed, as will not only prevent the contaminating result of decomposition, but will also stimulate and protect the living part immediately in contact.

These beneficial and highly important results have lately been ascertained, by practitioners of the first eminence, to have been derived from the local application of Barbadoes naphtha, after the failure of the usual remedies; the distressing symptoms of this alarming disease were soon alleviated,—the offensive fœtor quickly corrected,—and healthy granulations produced.

I have in a previous paper attempted to demonstrate that the seat of most constitutional diseases is in the absorbent vessels, and that carbon distributed through them, in many morbid affections, produces the most beneficial effects: I believe the only substance in nature which contains carbon in a large proportion, and in a liquid form, is the bituminous product from a mineral spring, called the "pottery," in the island of Barbadoes, (a specimen of which may be seen in the Museum of the Royal Institution, London;) from analysis, eight ounces yield seven ounces of carbon in its purest state, and in such a degree of exility, as to produce those active combinations, we never observe from the employment of common charcoal. In all organic arrangements,

carbon constitutes an important part, and probably its peculiar property of counteracting all morbid decompositions may be connected with some varied proportion of this active principle:—thus, in the process of respiration, carbon is evolved as a balance to what may be taken in food; and when the usual proportion varies, some derangement of the animal functions is indicated:—thus it was remarked by Dr. Davy, the extraordinary diminution of carbonic acid in the expired air of those who were attacked with cholera morbus.

I have been induced to submit these additional observations to the public, in consequence of the great beneficial results from the external application of Barbadoes naphtha in cases of extensive mortification.

The productive results of organic matter, decomposing slowly and gradually, are materially different from those arising from rapid destructive processes; thus the gentle effusion of naphtha, or the green rock oil of Barbadoes from subterranean vegetable deposits, possesses properties which cannot be traced in any of the artificial products of coal or wood, and hence the substitution of common tar should be studiously avoided, as we are not in possession of any chemical means by which the same combination of carbon and hydrogen can be effected, and upon which so materially depend its medicinal powers.

OBSERVATIONS ON MOTHERS' MARKS.

BY R. U. WEST, ESQ., SURGEON, HOGSTHORPE,
ALFORD, LINCOLNSHIRE.

*To the Editors of the London Medical and
Surgical Journal.*

GENTLEMEN,—I beg to forward you for insertion in your valuable Journal, if you should consider it worthy, the following case, which is rather a singular one, inasmuch as it would seem in some degree corroborative of the popular doctrine of *mothers' marks*.

A child was born about four years ago, with the fore and middle fingers of its right hand curiously deformed. They were much larger than the other fingers, hanging considerably beyond them, and were joined together as far as their extremities. The nails, planted side by side at the end of the united fingers, resembled in size and appearance the toe-nails of an adult male. The fingers were simply webbed together, but formed a

mass of considerable thickness, and not only was the hand rendered disgustingly unseemly, but it would have been utterly useless to the child, as long as it remained furnished with such an appendage. At the request of the mother, a few weeks ago, I amputated this monstrous production in the continuity of the metacarpal bones, so that the hand might in that part be bounded by a straight line, extending from near the extremity of the metacarpal bone of the ring-finger to the thumb. Very little blood was lost during the operation, and there were no arteries to tie. The wound readily united by the first intention, and is now quite well. I measured the monstrosity after it was taken off. Length from the metacarpo-phalanganian articulation to the extremity of the middle finger, four inches; girth at the nails, five inches; at the first phalanganian articulation, five inches and a half; thickness from the inside of the same joint to the knuckle, one inch and a half; breadth across the end of the two united fingers, two inches; of the nail of the middle finger, three-quarters of an inch; and this, it will be remembered, on the hand of a child only four years old. The bones are thicker than naturally they ought to have been, and the mass itself is formed by an increased deposition of fat around them; there is nothing of the nature of naevus about it. The mother says that, when she was pregnant, one of her other children had the fore and middle fingers of its right hand much hurt by their being jammed between a door and door-post. In great agitation she took the child on her knee, and held its injured fingers for some time *pressed together* in her hand. To this circumstance she attributes her child's misfortune.

The above is a much more plausible case for the believers in the influence of maternal impressions on the foetus, than another which I met with a short time since. A woman consulted me about a naevus in her infant's face, which was situated close to the inner canthus of one of its eyes, and was daily increasing in size. She had had a fright, she said, when pregnant, from seeing a child horribly marked in the same place. "And your infant was born with this mark?" "Oh, no, sir, it did not appear till it was more than a week old!" The notion of impressions being conveyed to the foetus by nerves in the funis, or by the

funis at all, must be abandoned after this. The influence, if influence there be, must have a more mysterious mode of travelling, even than that afforded by a few scarcely demonstrable nerves*.

CASE OF HYDATIDS OF THE UTERUS.

BY ROGER TURNER, MEMBER OF THE ROYAL COLLEGE OF SURGEONS IN LONDON.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—I beg to transmit for insertion in your widely extended Journal, the following case of hydatids of the uterus, should you consider it worthy of a corner in your pages.

Mrs. Burnett, aged 52, of spare habit and debilitated constitution, had borne several children, and menstruated regularly until within ten months of my first seeing her, at which time the catamenia became irregular, appearing at more frequent intervals and in less quantities; and ceased four months since, when her health gradually declined, the appetite became impaired, the abdomen enlarged, the legs anasarcous, was troubled with frequent pains in the lumbar region, with occasional discharges of coagula per vaginam; in consequence of the great severity of the pains, followed by a copious and sudden increase of the discharge, I was sent for in haste the 8th of May. On arriving at her house, I was informed by the attendants she had been in that state for two hours, and had had during that time tolerably strong bearing-down pains, resembling labour; pulse 110; a hard and frequent cough; abdomen as large as in the last month of pregnancy; bowels constipated. I introduced my index and middle fingers, and found the os uteri rigidly contracted, but in every effort of coughing there was a sudden gush of watery fluid, as in the escape of the liquor amnii in the first stage of labour. The hæmorrhage having abated, I prescribed an opiate, and medicines to regulate the bowels, and left, desiring to be sent for on the first occurrence of the flooding. The opiate allayed the cough, produced some comfortable sleep,

* It has been said, that nerves have been demonstrated in the umbilical cord.

and she remained in *statu quo* until the 11th, when the symptoms again returning with increased violence, a messenger was sent to me, but, before I could arrive, large coagula, with a great quantity of hydatids, had been expelled (sufficient to fill a large sized wash-hand basin and a half), accompanied by a profuse hæmorrhage, which had completely saturated the bed-clothes. I immediately gave half a drachm of *secale cornutum* in infusion, which increased the uterine efforts, but failed in expelling more hydatids; the genital fissures being in a lax state, I readily introduced my hand into the vagina, but the os uteri was so little dilated, I could barely pass the middle finger into the uterus; and, after considerable time, having managed to scoop away an additional quantity of hydatids, the pains and hæmorrhage ceased. I gave a full dose of opium, and, waiting upwards of an hour, there being no returns of the pains or hæmorrhage, and my patient disposed to sleep, I left her, directing to be sent for as before.

13th. No return of the more urgent symptoms; complains of pain in the head; bowels constipated, which I attributed to the opiate; cough, though somewhat better, still continues troublesome, and a constant escape of a colourless limpid fluid on every effort in coughing; the enlargement of the abdomen and legs had subsided.

15th. Was up, and enabled to walk about the room with a staff. Bowels open; cough and pains in the head less; a stillicidium of the fluid in the erect posture, though very trifling in quantity.

17th. Continues improving; is down stairs, although still weak; cough and headach have left her; appetite better.

21st. No bad symptoms have followed, and she appears now to be quite recovered.

Broughton, Stockbridge.

BRISTOL INFIRMARY.

[We have been requested by the surgeons of the Bristol Infirmary to insert the following corrected memorial, transmitted by them to Henry Warburton, Esq., M.P., with which we comply.—Eds.]

" To the Chairman and Committee on Medical Education, &c., &c.

" Gentlemen,—In addition to the answers to the questions contained in your circular, we beg leave to subjoin the following statement, to which we respectfully call your attention, as connected with the subject which must form no inconsiderable portion of your inquiries, namely, *medical education*.

" In the year 1735, Bristol projected, and in 1736 carried into effect, the scheme of a hospital, supported entirely by voluntary contributions. Its foundation is believed to be nearly coeval with, if not to have preceded, that of the hospitals in London, and of similar institutions in Scotland and Ireland; royal, endowed, and chartered foundations only excepted. This institution now contains from 200 to 220 in-patients—out-patients, from 5,000 to 6,000. Average number of casualties, about 1,200 annually.

" The whole range of building is uniform and extensive, having been re-erected within these few years; furnished with baths, warm air, and other modern conveniences; and has attached to it a spacious garden, as a promenade for convalescents; in a word, no expense has been spared which could contribute to the comfort and recovery of the inmates.

" This institution is also enriched with a valuable and daily-increasing museum; a library, a lecturing theatre, and excellent accommodation for examinations and dissections; in the latter of which our students are almost daily engaged, under the able superintendence of the house-surgeon.

" The ordinary disbursements are annually from 5,000*l.* to 6,000*l.*; and there has been lately expended, in providing accommodation for the out-patients, about 3,000*l.* in a supplementary building.

" It may not be aniss here to recount the advantages which the city of Bristol possesses for a great medical establishment. With a population equal to that of most of the capitals of Europe, with a large and well regulated hospital, and also a medical school, the student here may learn not only the principles and practice of medicine and surgery, but also witness, on a great scale, the nature of most of the diseases and accidents which afflict mankind.

"With the above statement before you, gentlemen, it will, perhaps, be a matter of surprise, that there could have existed any doubt of the propriety of conceding to us the ability to qualify any students for examination; yet the fact is, that it is only since the 26th Nov., 1831, that we have been 'recognised' by the College of Surgeons; and even then partially, as our dressing apprentices of five years' standing are at present under a peremptory obligation of *walking*, as it is termed, some one or other of the London hospitals, for a period of six months. On this subject it is remarkable, that the regulation of the College should only require a *walking* attendance of twelve months in a London hospital from young men who never before may have been within the walls of any hospital, while our apprentices have not only witnessed the practice of the Bristol Infirmary, but have been constantly employed as dressing pupils, and in the charge of casualties, for a period of five years.

"This representation, we presume, entitles the Bristol Infirmary to be justly considered a hospital of the first class. Even in the metropolis there are not above four or five that exceed it, either in size or importance, as a school for scientific and practical surgery; and none surpass it as to the regulations established by its governors for the education of the students: it may be asserted that no hospital in the kingdom affords greater opportunities for the acquirement of medical and surgical knowledge. On this subject the surgeons are desirous of the fullest investigation; and, as some proof, they beg to refer to every one of their students who have attended in London, who will confirm the fact from their own experience and observation. Besides, it is well known, that students, who have received their medical education at this Infirmary, have acquitted themselves with marked ability as candidates for their diplomas, when under examination at the College of Surgeons and Apothecaries' Hall.

"For these and many other reasons, the surgeons of the Bristol Infirmary have ever considered the following regulation of the Council of the Royal College of Surgeons as oppressive and unjust; but they are willing to believe founded on an erroneous view of the opportunities the Bristol Infirmary affords of cultivating medical science. Pupils and

apprentices, when candidates for the diploma, must bring proof—

"Of having attended, during twelve months, the surgical practice of a recognised hospital in London, Dublin, Edinburgh, Glasgow, or Aberdeen; or for six months in any one of such hospitals, and twelve months in any recognised provincial hospital."

"The surgeons of the Bristol Infirmary are of opinion that the above regulation of the Royal College of Surgeons,—which requires an attendance of six months, as a *walking* pupil, at one of the hospitals in London, in addition to an attendance during one or more years at a recognised provincial hospital, as a necessary condition for obtaining the diploma of the College, is highly objectionable; and for the following reasons:

"1st. Because it is unnecessary. A student may spend the prescribed time quite as profitably in attendance at a recognised provincial hospital, as upon those in London. In fact, with the exception of four or five of the metropolitan hospitals, the recognised provincial hospitals are upon a larger scale than those of the metropolis.

"2nd. Because it is injurious to the morals of students. It is a notorious fact that students, after a residence of only a few months in the capital, frequently fall into practices of dissipation and immorality foreign to their previous habits, and ruinous to their future usefulness, respectability, and happiness.

"3rd. Because it has a tendency to render provincial education less efficient than it would otherwise be. It has often been observed that students neglect to make a proper use of the advantages afforded to them in their attendance at a recognised provincial hospital, from a notion that the full prosecution of their studies may be delayed until their residence in London, where, they imagine, the opportunities of acquiring professional knowledge will be more worthy of their attention; and, in consequence, they crowd into that brief period a far greater number of pursuits than their time, or their previously-formed habits and inclinations, will enable them to follow with any prospect of advantage.

"4th. Because it occasions a very considerable increase in the pecuniary expenditure of the student, without advantages in any de-

gree correspondent to the extent of the outlay.

"Lastly. Because it implies an invidious distinction between the surgeons of the recognised provincial hospitals and those of the metropolitan institutions, a distinction which cannot be supported by a fair comparative estimate of their respective attainments and capabilities.

"In addition, we beg to draw your attention to the circumstance, that not only has the time prescribed for provincial study been of late considerably lengthened, with a corresponding augmentation of expense, but the number of branches of science which must be attended to has also been greatly increased.

"Gentlemen, we will take up your time no longer than to submit to you that we require redress; and to repeat that the Bristol Infirmary has a fair claim, in every point of view, for admittance into the first class of hospitals in the United Kingdom.

"We have the honour to be

"Gentlemen,

"Your most obedient servants,

"RICHARD SMITH,

"WILLIAM HETLING,

"RICHARD LOWE,

"HENRY DANIEL,

"NATHANIEL SMITH.

Foreign Medicine.

ACADEMIE DE MEDECINE.

Sitting, April 1st, 1834.

President—M. LISFRANC.

Discussions on Congenital Luxations of the Femur.

M. CAPURON stated that M. Breschet, on congenital luxations of the femur, has said, that the cotyloid cavity was in general effaced, which depends on the epoch at which these luxations are examined. If the subject has arrived at puberty, the cavity may have become obliterated; but is this the case a short

time after birth? I have, said this gentleman, recently been consulted about a girl 11 years of age, affected with this disease. M. Dupuytren had examined it, and discovered the nature of the lesion. I questioned the mother as to the circumstances of her accouchement; she told me that the buttocks of the infant presented at birth, and, to favour her delivery, the sage-femme had applied, on the groins of the infant, her fore-fingers, bent in the form of hooks. We may conceive that such a manoeuvre can act directly on the ileo-femoral articulation, displace the head of the femur from its cavity, and stretch and distend the capsule. In this case, was not the supposed congenital luxation produced by the midwife? I know a young lady, 20 years of age, the mother of whom I attended in her confinement. This was a similar presentation, and she was delivered without the employment of any manoeuvre. As soon as the child commenced to walk, I recognised, not precisely a luxation, but a difficulty to proceed—a kind of claudication, which caused her progression to resemble that of a duck. The mother had a similar deformity, and, upon inquiry, I found she was born in a similar position. I think it, then, right to call the attention of midwives to this species of accouchment in its relations with congenital luxations of the femur.

M. Breschet replied, that, in every dissection to the present day, congenital luxation of the femur always presented itself under invariable characters—total absence of the cotyloid cavity, of the neck, and even of the head of the femur, or, at best, a rudimentary state of all these parts. We can consult the figures given by *Palletta*; and I have myself examined these luxations at different ages, and even a very short time after birth; and the manner in which the trochanter major moves on the os ilium has fully convinced me of the absence of the head and neck of the femur, and consequently of the cotyloid cavity. I deny not, however, the facts advanced by M. Capuron; his views appear to me very judicious, but they have not the advantage of demonstration, and it is of the highest importance that obstetricians should verify them.

M. H. Cloquet.—M. Capuron confounds congenital luxation with that produced accidentally by the manoeuvres of midwives. I have seen in an aged female, in consequence

of spontaneous luxation of the femur, the cotyloid cavity obliterated, and the head of the femur diminished half its volume; we must not mistake this for congenital luxation.

M. Velpeau.—All surgeons are aware that in old accidental luxations the cotyloid cavity is more or less in a state of obliteration, and that the head of the femur is somewhat deformed. This is not the most important point in the question raised by M. Capuron, and the object is to know if these luxations, called congenital, take place really in the uterus, or from the mechanism used in delivery; and the question reduces itself to this—are children attacked with congenital luxation found to have had a breech presentation? For my part I regard as very probable the opinion of M. Capuron.

M. Breschet reverted to the characters of congenital luxations that M. Velpeau had wrongly compared to those produced accidentally; in the latter, the cotyloid cavity is greatly decreased, though traces of it are always found; in the former, there is neither head nor neck of the femur, nor any cavity.

M. Moreau.—I should say, that to the extent of my knowledge those infants, born with breech presentations are all as straight, and walk as well as others. If by some ill-directed manœuvre a luxation has been produced, I should believe that it depended less on the presentation than on a certain predisposition in the infant, in the same way that we must have recourse to predisposition, in order to explain how a fall on the trochanter major produces in many infants only slight pain, and in others causes a spontaneous luxation of the femur. Besides, the facts brought forward by M. Capuron do not appear to me very decisive; at least that of the young lady who walked, as he stated, like a duck; it is a progression more or less common to all women, and a considerable width in this young lady's pelvis would sufficiently explain its being carried to any extent, the neck of the femur projecting directly outwards.

After a short reply from M. Capuron, the discussion terminated.

Secondary Small-pox.

M. Bouillaud.—As in several of our former sittings we have taken into consideration the occurrence of small-pox after vaccination, and

as the fact has been doubted by several members, I think it right to inform the Academy that I have at this present time under my care, at la Charité, a young man who has very perfect cicatrices of vaccination, and who is nevertheless attacked with confluent variola. I should wish that a member of the vaccine commission should be desired to visit this patient, and give some account of the case to the Academy.

M. Grinelle mentions a young girl who had small-pox at the age of six months whilst at nurse; very distinct cicatrices have remained all over the body, and now she is attacked with well-characterised symptoms of distinct variola.

M. Cornac knows a lady who, after inoculation at the age of eight years, had the usual symptoms of this disease, notwithstanding which, at the age of fourteen, she was attacked with a confluent species, which has left dreadful traces of its ravages.

M. Salmade.—I have myself noticed similar cases; authors are full of them, and it is so well known, that it cannot be necessary to bring forward additional facts for its support.

M. Bouillaud.—The importance of my communication does not lie there; we had seen cases of secondary small-pox, but their severity was not acknowledged, and they were even distinguished by the term of varioloid diseases; however I have already mentioned a fatal case of secondary variola, and the patient now under my care is so severely attacked that death may probably ensue.

MM. Lens and Cornac were desired to visit M. Bouillaud's patient, and communicate their report to the Academy.

White Oxide of Antimony in Pneumonia.

Some of the Parisian physicians have lately lauded the white oxide of antimony as a most efficacious remedy in pneumonia. "For females and young subjects," says one of our contemporaries, on the authority of M. Trousseau, "we may commence by giving twenty grains of the white oxide; if for adults or old people thirty grains. The dose may be increased by one-half on the next day; and this should be continued until the febrile symptoms are entirely removed, or even rather a few days longer. The dose should now be dimi-

nished gradually in proportion as the patient takes aliment."

M. Bouillaud, one of the ablest professors in Paris, observed, at the commencement of his clinical lectures, last month—

"The white oxide of antimony, so vaunted of late to combat acute pulmonary affections, has been experimented upon with the greatest care in his clinic; it was administered pure, and washed as recommended; its physiological and pathological effects were completely null; it only acted as an inert powder either given internally or mixed with the blood. The circulation, which was said to be arrested by its administration, had not been at all influenced: it was dissolved like sugar, and did not produce diarrhoea or vomiting. Placed in immediate contact with the blood, it did not impede coagulation, but when it was not pure, and only by the alkali which it contained."

Here is a vast diversity of opinion on the effects of the same medicine, which can only be accounted for by the adulteration of the article. We remember, some years since, when antimonial powder was pronounced inert, after repeated trials in one of our largest hospitals; but there is good reason to believe that an impure medicine was tried. There is one thing important with regard to the exhibition of antimony to children, which is, the danger of exciting inflammation and ramollissement of the stomach, which, at this age, is generally irritated by improper food. We have known death produced in this manner by tartarised antimony in pneumonia; and most practitioners prescribe ipecacuanha in that disease.

Digitaline.

M. Lancelot, apothecary at Chatillon, has succeeded in obtaining the active principle of digitalis, which he has named *digitaline*, and which has analogous effects as the former. It is white, acrid, and very soluble.

**ELECTION FOR ASSISTANT SURGEON
AT ST. THOMAS'S HOSPITAL.**

An election for the above named medical officer took place on Wednesday week last, at St. Thomas's Hospital, when Mr. J. F. South, of Upper Stamford-street, was duly elected Assistant-Surgeon to the Institution.

THE
London Medical & Surgical Journal
Saturday, May 10, 1834.

COLLEGE OF PHYSICIANS—VINDICIÆ
MEDICÆ.

THE case of the College of Physicians is now laid before the Parliamentary Committee, and the inquiry into the state of that Corporation is, we may venture to say, concluded. After the examination of the President and many of the Fellows, no further information as to its principles and practice remains to be collected; and, although the tribunal was not precisely that which the College desired, we readily believe, for we should be sorry it were otherwise, that every thing which could be said in its defence has been fully and impartially heard and reported.

Some recent publications have recalled our attention to the present position of the College. The latest of these it is our intention to notice before we close this article. In the meantime, at the hazard of repeating some observations already to be found in the pages of this Journal, we shall make a few remarks upon the history of the College, and the not improbable intentions of its founders.

How different has sad experience shown that history to be, from the consequences which might have reasonably been, perhaps had been, anticipated by a sober-minded legislator at the date of the charter! The charter incorporates the six distinguished physicians named in it, together with *omnes homines ejusdem facultatis de et in civitate prædictâ*, and gives the Corporation the most ample powers of control over the whole medical affairs of the metropolis and its vicinity. Such, in few words, is the whole charter; and nothing

can be more comprehensive in its designation of members, or more extensive in its powers.

Are we wrong in attributing too refined a policy to the advisers of Henry VIII., when we say that in giving such a charter they acted designedly and deliberately, upon the reasonable principle that medical men were fittest to legislate for their own profession; and that they accordingly did invest them with the power of framing laws for their government from time to time, adapted to the varying condition of society? It cannot, at least, be denied, that the charter was broad enough to comprise within the Corporation every legitimate practitioner of medicine at all future times; and that, under its lawful powers, the College of Physicians might have been the one Corporation of the whole Faculty of Medicine in the kingdom. No person can assert that we have strained the construction of the charter: it appears to us impossible to read it without feeling the force of our observations upon the glorious opportunity there was once presented of making it the *Magna Charta* of the profession.

A spirit of a very different kind very soon influenced the Corporation. The spirit of selfish monopoly prevailed; and the struggle, down to the times of Lord Kenyon, has been to limit the Corporation within the narrowest possible boundaries. The first consequences of this abuse of the charter may be traced in the elevation of pure apothecaries to general practitioners. The scanty supply of licensed practitioners admitted by the College, and their attempt to monopolise the whole practice of the metropolis, were the true grounds of that decision of the House of Lords, which has ultimately reduced the influence of the Corporation to zero in the republic of medicine, and

made the empire pass to the Hall at Blackfriars' Bridge.

In the time of Lord Mansfield an effort was made by the Licentiates to open the College, by disputing the legality of one of its elections, because the Licentiates had not been allowed to vote. In this form of the question, the technical objection, that a Licentiate, being admitted merely to practise, was not actually a Fellow, prevailed: but doubts were thrown out, and a strong opinion expressed by the Court that he had a right to claim admittance to the Fellowship; and that his total exclusion by the then by-laws was illegal. The right was not tried at the period. The College took the hint, and, by the advice of counsel, determined what was the smallest possible opening to be conceded to the Licentiates short of total exclusion, in order to satisfy the reasonableness of the law. When the question of right was at length fairly raised, the prejudices of Lord Kenyon, who loved to contradict Lord Mansfield, and again reduce the common law to its meagre subtleties, prevailed; and it was held that the President's privilege of introducing an odd Licentiate now and then, to be exercised according to his caprice, and a like power to the Fellows, which has never been exercised at all, satisfied the scruples of the law in favour of liberty. The subsequent history of the College would be a repetition of its history within the last few years. We think we have accounted sufficiently for its total loss of all influence in medical affairs. Whatever difficulty there may be in restraining the other bodies which have risen upon its ruins, it can offer no impediment to the reconstruction of the Profession upon the basis it has so shamefully deserted.

The pamphlet which has led us to

make these observations is from the pen of Sir George Tuthill. With a happy imitation of Milton, Mackintosh, and Southey, the learned knight has adopted the imposing title of *Vindicta Medica*, which, for the sake of the unlearned, he has translated into *A Defence of the College of Physicians*. It is dedicated to Sir Henry Hallford. Our reasons for always reading a preface or a dedication may be found at large in D'Israeli's *Curionities of Literature*. Our readers, we hope, have a like taste, and may, perhaps, have a fancy to see how congenial spirits greet each other. Take, for example, then, the preface before us:—

"Dear Sir Henry,—May I beg you to accept this defence of the College, both as a tribute of duty and as a token of regard? There is no one who is more devoted to the interests of the College than yourself, nor is there any one who has contributed more largely to its fame. But you so much excel all others in that kind of writing which you have undertaken to adorn, that I should have felt an invincible reluctance to submit myself to your judgment, had I not known that a rare facility in detecting the errors of others is usually combined with an indulgent disposition to forgive them, and that by the expression of sentiments, which may claim a near kindred to your own, I may confirm the friendship with which you honour me.

"I remain," &c. &c. &c.

This dedication unwittingly discloses two most important facts;—first, that Sir Henry Hallford is the most distinguished member the College has ever had! and, secondly, that the excellent author of the pamphlet has endeavoured to produce a piece of composition worthy of the eminent body, whose president is renowned for the graceful elegance of his classical

essays, whether the same essays be in Latin or in English. We pretend not to judge of either of these serious matters. In that which is within our province and the scope of our common capacities, we venture to entertain an opinion, and we have accordingly the hardihood to pronounce that the pamphlet in question is but a dull repetition of the dull contents of a certain anonymous pamphlet, lately published in defence of the College, and reviewed in this Journal. The eminent writer takes the fifteen sections of the petition of the Licentiates as so many texts, which he undertakes categorically to answer and refute. We are tempted to quote the first of these sections, and a portion of the answer to it, as a specimen of the whole.

I. "That the Charter of the Royal College of Physicians of London was granted by Henry VIII., for the advancement of medical science, and for the protection of the public against the temerity of wicked men, and the practice of the ignorant." If there be a position in the petition out of the reach of controversy, we should say it was this. Far otherwise thinks "the profound, sad and discreet, groundly learned, and deeply studied in physic," pamphleteer, who observes in

"Answer. This first paragraph of the petition involves a *subtle inference*, which makes no part of the charter." He then sets forth the whole charter; whence he plainly concludes that it is not, and never has been, the object of the College to favour "the advancement of medical science." The "answers" to the other allegations of the petition consist in general of wholesale transcripts from the decisions of the judges, many years ago, in the two cases we have alluded to. How utterly impertinent to the real question at issue these decisions are it is scarcely necessary to point out. The real question

is, whether the College has put a *judicious* interpretation on its charter, and not whether its by-laws were not exactly so unreasonable, as to call for the interference of the Court of King's Bench fifty years ago, an immense stretch in the age of the world. We find no original composition of the learned writer worth mentioning till we come to his comment on the eighth section, which avers the usurpation of all corporate powers by the Fellows. In reply to this allegation we have, in the first place, an essay upon the utility of the division of the College into two orders.

"Can it for a moment be contended that because a man has been properly admitted a Licentiate of the College, he is *ipso facto* qualified to be elected its president? Must no man be permitted to serve the people in parliament who is not fit to be a minister of the crown, and to guide the vessel of the state in every storm and in every danger? In all bodies of men, associated for their own government and for the government of others, is it not shown to be useful, by experience and by universal consent, to *select* a council, in whom the wisdom of direction is presumed to reside?" In this choice passage it is assumed that every *Fellow* is qualified to be elected president; that the president *et hoc genus omne* are as ministers of the crown, and the rabble of Licentiates as mere members of parliament; and that the odour of *self-elected* vestries, and all other self-elected governing bodies is particularly sweet. But, in the second place, in reply to the allegation that Licentiates are excluded from corporate offices, we are treated with a legal dissertation on equivocation, and a serious charge of suppressing a portion of the truth is, with unparalleled effrontery, imputed to the respectable petitioners. It is true, says the pamphleteer, that a Licentiate is ex-

cluded, so long as he remains in the order of *Licentiates*, but he does not necessarily remain in that order; *Licentiates* are elected into the *Fellowship*, and become thereby eligible to every office which the College contains. Such is the *suppressio veri* upon which is built this foul and calumnious imputation! and with such a specimen of the critical acumen of the learned pamphleteer we shall conclude our brief review of the most worthless pamphlet the present crisis has produced, which nothing but the respectable name attached to it should induce us to notice.

SIR EVERARD HOME'S LECTURES ON COMPARATIVE ANATOMY.

This elaborate work is now on sale at the very reduced price of eight guineas, small paper, published at eighteen guineas; and twelve guineas, large paper, published at twenty-six guineas. Upwards of seven hundred copies (out of the edition of one thousand) having been disposed of at the original price, it is presumed that an early application will be necessary to secure copies upon the terms now offered. Vols. III. to VI. may be had to complete sets, at half price. Every public library ought to have a copy of the best national work on this interesting branch of science.

French Hospital Reports.

HÔPITAL DE LA PITIE.

Pericarditis with sero-sanguinolent effusion—Death—Necropsy—False Membranes, without material alteration of the Pericardium.

A MAN, aged 50, was admitted on the 1st of April, complaining of pain in the præcordial region, and a little towards the left lateral wall of the chest. He applied, without medical aid, fifteen leeches, which relieved the pain. He stated that he never had rheumatism.

Auscultation indicated no anormal sign; percussion afforded a dull sound in the præcordial region, and at first there was a slight

bruit de râpe, which daily became more manifest. There was great debility, heat of skin, thirst, want of appetite, and frequent pulse. He was bled largely on the first day, which was repeated in a few days, as the action of the heart had continued.

8th. The symptoms were continued, and two blisters applied to the legs.

12th. Less debility; more loquacious; delirium; startings of the tendons; tongue dry and fuliginous; *bruit de râpe* is manifest; pulsations of the heart dull and profound; pulse small and contracted. Death on the 13th, at night.

Autopsy, thirty-six hours after death.—The lungs were sound; the left adhered slightly to the chest; heart natural; pericardium covered throughout its extent with false membrane of a line in thickness. This membrane was red and rugous, and easily detached from the pericardium with the scalpel; and this last was perfectly sound inferiorly. In the interior of the cavity of the pericardium, there was a great quantity of sero-sanguinolent fluid. All the cavities of the heart were natural. A polypiform concretion occupied the interior of the aorta from its origin to its bifurcation, and extended into its divisions.

The cerebral membranes were strongly injected and adherent to the brain. The cortical substance was also injected. There was a small quantity of serosity in the ventricles.

The intestines and other organs were natural.

M. Rostan formed an accurate diagnosis during life; his conclusion was pericarditis and effusion.—*Lancette Française, Gazette des Hôpitaux Civil et Militaire.*

Vaginitis, with Profuse and Fœtid Discharge, Limpid and Uncoloured, occasioned by a piece of Sponge in the Vulvo-Uterine canal.

BY M. J. J. CAZENAVE, M.D., BORDEAUX.

A midwife conducted to me a young delicate person, of a lymphatic temperament, who complained of a very abundant vaginal discharge, which was limpid and uncoloured, but very fœtid. In reply to my questions she stated that her discharge was of four or five days' duration, about which time she yielded to the solicitations of a gentleman. She experienced great pain in the neck of the uterus

after coition, which was almost immediately followed by the vaginal discharge.

She refused to submit to examination. She was ordered astringent and disinfecting injections of chloruret of sodium.

She called next day, and stated, that having used the bidet that morning (*les cuises étant très écartées et la vulve entr'ouverte*) she observed that a soft substance escaped, giving out the odour of putrified animal matter, which was a piece of sponge that had been introduced immediately ante coitum, *pour s'opposer la fécondation*. From this moment the discharge and its bad odour ceased.—*Bull. de Bordeaux.*

HÔTEL DIEU.

Baron Dupuytren's Clinic—Syphilitic Ulcer of the Upper Lip, resembling a Malignant Pustule.

Elizabeth Hénin, aged 26, of good constitution, admitted the 9th of April, with an ulceration on the left side of the upper lip, into St. Agnes' Ward, under M. Dupuytren. At first view this ulcer had all the appearances of malignant pustule; as, however, its progress was slow, emollients alone were applied; gradually the affection assumed a syphilitic aspect.

The patient was immediately submitted to an anti-venereal treatment. Infusion of sarsaparilla with sudorific syrup; corrosive sublimate, gr. $\frac{1}{8}$; guaiacum, gr. iij; opium, gr. $\frac{1}{4}$; of which she took one pill three times a-day. Under this treatment she gradually improved.

Fracture of the Inferior Extremity of each Radius from a Fall on the Palms of the Hands—Imperfect consolidation on the Right Side—Apparatus employed on the Left.

A. B., a woman, 58 years of age, a water-carrier, came into this hospital the 14th of March last, with fracture of both radii; that of the right side cured with imperfect consolidation, that of the left more recent. Fifteen months since she was admitted into another hospital for the first accident; when she left it, she was unable to carry her arm to her head, and since then the limb has become nearly useless.

By passing the hand along the external

edge of the fore-arm, a depression is found on a level with the old fracture, evidently owing to a depression of the fragments of the radius; the hand is thrown a little inwards and the inferior extremity of the ulna is remarkably prominent under the skin. Both accidents were produced by falls on the palms of the hands; in the first, she was going down stairs, carrying two buckets of water; in the second, also going down stairs, but without any load. This was on the 13th of March, at eight o'clock in the evening; she accidentally trod on a rat, which caused her to slip, and in attempting to save herself, fell on the palms of her hands; the radius was fractured near its inferior extremity; a severe pain was produced, and the motions of pronation and supination were thereby rendered impossible. On her admission to the Hôtel Dieu the nature of the accident was immediately recognised, and a proper apparatus being this time applied, the fracture is rapidly uniting; these cases, remarked M. Dupuytren, generally get well after five and twenty or thirty days.

Sprain—Erysipelas on both sides of the Face, and Abortion.

Marie Hugo, aged 22, admitted in the Hôtel Dieu on the 8th of April, with sprain of the left ankle-joint; this had been nearly cured by the general treatment, when erysipelas broke out on both sides of the face; this was treated by blistering, emetics, and purgatives; the patient had escaped these accidents, when suddenly abortion took place; she had concealed her pregnancy, which was of six months' duration. Notwithstanding these complications, the patient is now in a fair state of recovery.

This case illustrates the obstetric axiom that external injury of any kind may induce abortion.

Oblique Fracture of the Tibia, with Tardy Consolidation.

A washerwoman, aged 69, was admitted on the 4th of February, with oblique fracture of the left tibia; the usual means were adopted, without the anticipated success. M. Dupuytren, in order to remedy the projection of the upper fragment of the tibia, has applied graduated compresses, under the former apparatus, to the internal surface of the tibia and interosseous space, over these he laid two thin wooden splints. This treatment will probably be successful; since its application the patient has been perfectly easy.

British Hospital Reports.

ST. GEORGE'S HOSPITAL.

Stricture.

It will be remembered that, in a former number, when speaking of those cases of stricture in Egremont Ward, under the care of Mr. Brodie, we noticed one, the symptoms of which were of a bad character, and had been present for some time. Of this case we subjoin the following report:—

Joshua Maskell, a pale, unhealthy-looking man, was admitted into Egremont Ward, under the care of Mr. Brodie, for severe stricture at the posterior part of the canal, accompanied with a highly irritable and inflamed state of the living membrane of the urethra. The prepuce was also abnormally elongated, from a vicious habit contracted in early youth. The patient took a variety of medicines at various times to keep down the irritation caused by the introduction of the catheter or bougie at various times; but nothing was found to subdue this so well as perfect repose. There were numerous false passages in the urethra, and one of these, which had been originally caused by an abscess, was fistulous, and opened into the perinæum. Mr. Brodie introduced a bougie very carefully into the bladder, and let it remain in for twenty-four hours. This, however, was followed by great swelling of the glans penis and cellular membrane of the parts; and Mr. Brodie observed, that although at first it might seem like a loss of time to keep the man in bed, and do but little or nothing for him, yet this was highly necessary in a case like this, where the constitution was very much shaken, and the general health greatly impaired; and the good effects to be seen from this treatment were visible in the general improvement of the patient's health, and the altered state of his urine, from a highly loaded and impure condition to one of an equally healthy character.

March 6. He has taken the saline draught of the hospital every six hours, and takes beef-tea and arrow-root for his diet, and his two ounces of port wine were ordered to be increased to eight ounces every day. He looks worse than at the last report, and the urine passes entirely through the fistulous opening; the swelling of the glans penis has entirely subsided.

April 21. He has continued much the same since the last report; he continues to take his beef-tea and wine, and cascarella draughts with carbonate of ammonia three times in the day. His general state of health remains much the same as at the last report.

We saw him again one week afterwards, but little change had occurred; an instrument could be passed with somewhat more of ease into the bladder; and, as the local disease was somewhat improved, and his general constitutional health appeared to suffer from re-

maining in the hospital, he was ordered to be made an out-patient for the space of one month, and, at the end of that time, to present himself again for admission.

Ann Bennett was admitted into Drummond Ward in March, under the care of Mr. Brodie, with pain in the right knee. From what she states it appears that some years since she had inflammation of the knee-joint, and for which she was an in-patient in the Middlesex Hospital for a twelvemonth, under the care of Sir Charles Bell, who treated the case with an issue on each side of the knee, and she went out perfectly cured. Many of the symptoms have, however, again returned, and she has, by the advice of some professional man, been rubbing in the tartar emetic ointment, as the joint is now completely covered with pustules. Mr. Brodie, upon hearing the above account, and examining the shape and size of the two knees together, was of opinion that there was nothing of any material consequence affecting the knee at present, and was inclined to believe that the pain was more of an hysterical character than any thing else. In order to confirm this view, the various tests of proof were resorted to as usual in such cases, but nothing seemed to alter the original complexion of the case, and Mr. Brodie still remained at a loss to know whether the case was one of original disease or not. The girl could not bend the knee without great pain, and whether it was moved or at rest, the pain is referred to a line across the knee, nearly even with the inferior border of the patella. Pressure of the articulating surfaces of the condyles together gives no pain, nor is any great uneasiness experienced when the patella is pressed upon. The girl has an hysterical look, and it was suspected that she was pregnant, but this we believe is doubtful.

28th. She has had some increase of pain in the joint for some days past, which has been relieved by the application of a cold saturnine lotion to the part. The pustular eruption, caused by the tartar emetic ointment, has nearly entirely subsided, with the exception of one hard, dry scab; which has not separated. Mr. Brodie significantly asked what could be the reason this did not come off. The house-surgeon replied that it might be from the cold lotion, which was known to prevent the healing of leech-bites. Mr. Brodie ordered a poultice to be applied to aid its separation, and with reference to the application of the tartar emetic ointment, he thought that it was a bad thing; he had known one person lose his limb, and another very nearly lose it, from the tartar emetic ointment causing a large ulcer, which spread rapidly, and assumed a very unhealthy

appearance. He thought the sulphuric acid liniment* was a much better application. The tincture of iodine was a very good application for the purpose of making an eschar; if the skin was touched for several days in succession with a camel's hair brush dipped in the tincture of iodine, the skin would be raised into a blister, which might easily be kept open.

The girl was ordered to take some camphor mixture with the syrupus croci for a short time, in the course of which all her bad symptoms and pains subsided, without the aid of any other medicine whatever, and in a few days afterwards she was discharged.

CORRESPONDENTS.

Mr. Stanton.—The experiment is not likely to succeed.

Oxon.—Assertion is not proof.

A. B. C.—There will be a radical change in the medical polity of the United Kingdom.

An Old Practitioner.—There will be an Obstetric Board in London. We agree with our correspondent: there should have been one two hundred years ago.

Avicenna.—It is probable that there will be a National Medical Board, composed of three sections,—one for England, Ireland, and Scotland. The Imperial Parliament recognises Great Britain and Ireland as one country; and thinks the time for partial legislation has gone to the tomb of all the Capulets.

A Friend to Humanity.—There cannot be a second opinion that Mr. Warburton is one of the best friends of the public and the medical profession. He will be the mover of a legislative enactment which will never be forgotten to the latest posterity.

An Observer.—We heard Mr. Green's evidence; it was what it ought to be, that of an eminent surgeon and a gentleman. We were delighted with his inculcation of the necessity of good moral conduct in medical practitioners. He defended ethics, though some who never knew the meaning of the term have styled it folly.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECT. LXXXIX., DELIVERED APRIL 17, 1833.

GENTLEMEN,—*Amaurosis*, or *gutta serena*, is an obscurity or loss of vision, arising from a more or less insensible state of the retina. Either the retina, the optic nerve, or the brain, may be the part first and principally affected. The expression *gutta serena* is only applied to cases of total blindness, plainly derived from the circumstance of the pupil having no opacity in it, and seemingly being clear, though the patient is blind.

The symptoms of amaurosis are of two kinds; first, those which the *surgeon* notices in the *form, colour, texture, consistence, vascularity, and mobility* of the *different parts* of the *organ*, or in the general health of the patient; secondly, those which the *patient* himself experiences, as *impaired or deranged vision, headach, vertigo, peculiar sensations in the eye, &c.*

The first symptom, gentlemen, and one that never fails to be present, is the patient's want of a proper control over the eye affected, the pupils of the two eyes not being directed harmoniously to the objects looked at; and hence there is something staring and vacant in the patient's countenance. This symptom may indeed exist at first only in a very slight degree; but, in some cases, it amounts to an actual squinting, or strabismus, while, in others, such is the want of control over the eye, that it is either affected with oscillation or stands quite motionless in the orbit. Then, gentlemen, I may observe to you, that the motions of the eyelids, as well as those of the eyes, are likewise not unfrequently interrupted; sometimes the levator of the upper eyelid being palsied; and sometimes the orbicularis palpebrarum.

VOL. V.

The eye may also form a greater prominence than the other, or be otherwise changed in its shape. Its colour is seldom that exhibited in the healthy state, the sclerótica being yellowish, bluish, or ash-coloured, and often streaked with varicose vessels; while no symptom of amaurosis is more to be depended upon, than an increase or diminution in the natural firmness of the eyeball.

Another usual symptom is a *sluggish and limited motion of the pupil*, generally attended with *dilatation*, but occasionally with *contraction* of that aperture. The early and incomplete stages of amaurosis are, indeed, rarely accompanied by a widely dilated pupil; but after the perception of light has become further weakened or extinct, the opening is commonly expanded and quite motionless.

But, gentlemen, you will sometimes meet with cases in which the *pupil of a completely amaurotic eye will move briskly*, according to the degree of light acting upon the opposite or sound eye; though, if the amaurotic eye alone were exposed to its influence, the pupil of it would remain perfectly motionless and greatly dilated. Hence it is a rule in surgery, always to close and cover the sound eye during the examination of the state of the iris and pupil of an eye suspected to be amaurotic.

Gentlemen, you may also meet with examples still more curious, in which, though the patient is totally blind, both pupils vary in diameter, according to the changing degrees of light, exactly as they do in the perfect state of the eyes.

Besides the motions of the iris, which must be examined in each eye separately, and with the opposite eye excluded from the light, the shape and situation of the pupil should be noticed, and the inclination of the iris considered, for sometimes the pupil is irregularly dilated, and sometimes moved towards a particular point of the circumference of the iris, while this membrane itself may either bulge out towards the cornea, or sink back, so as to present a concave appearance.

When amaurosis is an effect of hydrocephalus in a young subject, the pupil may exhibit its natural black hue; but in elderly

subjects, amaurosis is almost constantly accompanied either by some degree of glaucoma, or a dull glassy or horny appearance in the pupil.

The want of control over the eye, the inability to direct the pupils harmoniously, the change in the shape and consistence of the eye, the sluggish motion and dilatation of the pupil, subject to the exceptions specified, the alteration in the shape and position, and the glaucomatous or hornlike colour of the pupil, are then, gentlemen, the chief things which you will be able to examine by the evidence of your own senses in cases of amaurosis.

Now, the symptoms or effects, of which the patient alone is conscious, are, first, *impaired vision*, the progress and degree of which vary in different cases; for, in some instances, the patient becomes suddenly and permanently blind, while, in others, the sight diminishes in a very slow and gradual manner, without ever terminating in total blindness.

Hence the distinctions of *complete* and *incomplete* amaurosis. Frequently, in the commencement of the disease, the failure of sight is only occasional, or for a short time, or periodical, assuming the form of *night blindness* or *day blindness*, or coming on after any great exertion of the eyes. A few lines of a printed book may perhaps be read, after which the letters appear completely confused.

The failure of sight may extend to the whole field of vision, or only to a part of it. Thus more or less of the page of a book may not be visible (*visus interruptus*); or only the half of objects may be seen (*hemioptia*). Sometimes objects can be seen only when placed exactly in one particular direction (*visus obliquus*). To some amaurotic patients all objects seem disfigured, crooked, enlarged, diminished, or even inverted (*visus defiguratus*).

Then another common sign of amaurosis, which the patient experiences, is what are termed *ocular spectra*, as *sensations of flashes of light* in the eye (*photopsia*), or of insects or cobwebs flying about before the eye (*muscae volitantes*); or of colours which are not before the eye. *Double vision* is also another frequent effect of the disease in its early stage. As the complaint advances, however, vision is obscured by one uniform cloud or network.

In the early periods, the patient has sometimes an unwonted sensibility to light, which even gives him pain; while, in other more usual cases, he always courts it from the very beginning. Pain in the eyes, head, and face, is another important symptom in amaurosis, denoting the probability of the existence of a slow inflammation of the retina, or of organic disease within the cranium itself; for, gentlemen, you should be aware, that many of the causes of the incurable forms of amaurosis act on the nervous structure of the eye from within the skull. Such are collections of fluid in the ventricles of the brain in hydrocephalus; disease or tumours of the brain situated near that

part of it where the optic nerve is connected with the base of the brain; while other swellings or diseases may affect the optic nerve in its course either within the cranium, or in the orbit.

Gentlemen, you already know, that loss of sensibility in the retina, and a complete annihilation of its functions may be the effect, or accompaniment of other diseases of the eye; as, for instance, of the severe varieties of ophthalmia affecting the interior texture of the eye, glaucoma, hydrophthalmia, melanosis, and fungus hæmatodes. These examples, in which the retina suffers, in common with other textures, are named according to the primary disease, or to their most prominent symptoms; and when we use the term *amaurosis*, we commonly understand a case in which the retina, or nervous apparatus of sight, is the part of the eye first affected.

Immoderate exertion of the eye in the various occupations of life, more especially on small objects, and in persons either of plethoric constitutions, or intemperate habits, producing a determination of blood to the head, may be set down as frequent causes of a slow inflammation of the retina, ending in an alteration of its texture, and in impairment or abolition of its functions. Hence printers, watchmakers, engravers, tailors, and other classes of workmen, whose eyes are employed on minute objects and needlework are frequently afflicted with amaurosis.

Amaurosis, gentlemen, is sometimes divided into *functional* and *organic*, the first implying the interruption of the functions of the retina, independently of any organic disease. Whether such case really occur has sometimes been disputed; but, if we admit that amaurosis may arise from sympathy of the eyes with disease or irritation in distant parts, we must, I believe, admit the *doctrine of functional amaurosis*. Thus you will meet with cases of amaurosis from gastric disorder, from the presence of worms in the bowels, from the irritation of dentition, and from that of a carious tooth. You will see the disease arise from a wound of the scalp, caries of the skull, disease of the antrum, abscesses about the face, the suppression of the menses, or the effect of particular aliments in persons of peculiar idiosyncrasies.

With respect to the prognosis, the functional amaurosis must leave a greater hope of cure than the organic. A suddenly formed amaurosis is generally less unfavourable than one, that has developed itself slowly. Complete inveterate amaurosis, attended with organic change of the retina, or optic nerve, may be deemed incurable. The distorted appearance of objects in the early stage is always a bad omen, because indicative of disease in the brain. With respect to the liability of amaurosis to be mistaken for incipient cataract, the difference will be explained when I speak of the latter disease. Amaurosis may be combined with glaucoma, or with cataract.

With regard to the *treatment of amaurosis*, I may say, gentlemen, that no directions can be of any value, unless founded on a correct view of the causes of the disease, or supported by successful experience. No doubt much of the difficulty of curing amaurosis arises from our being frequently ignorant of its causes; to their being in many instances various, complicated, and incapable of removal; or, if removable, to the impossibility of obviating the effects left on the retina.

When you find amaurosis attended by signs of determination of blood to the head, such as *headach*, *vertigo*, flushed countenance, and arterial throbbings of the temples; that the pulse is full, and the subject young and plethoric, you should employ general and local blood-letting, and purgatives, and put the patient on a very low diet. If the case be altogether dependent upon vascular distension, these means, conjoined with rest of the organ, will probably effect a cure. If along with vascular fulness there be effusion, depletion will be the most likely means of relief, and the best preparation of the patient for other remedies, more especially for the use of mercury.

When functional amaurosis depends upon disorder of the chylopoietic viscera, habitual costiveness, and an increased flow of blood to the head, purgatives, assisted by bleeding, are found to answer better in this country than nauseating doses of tartrate of antimony, so highly praised on the Continent. You may give the blue pill at night, and a mild saline aperient mixture in the morning; and, after having continued this treatment for some time, tonics may be prescribed with advantage, as sulphuric acid, bark, and steel medicines.

It cannot be doubted, that many examples of amaurosis depend upon the effects of chronic inflammation on the retina, or upon a slow and gradually-produced deposition of lymph in various situations affecting the immediate organ of vision. Now, for the diminution and removal of such effects, we know of no medicine that is at all equal to mercury. I fully agree with some other practitioners, that the right treatment of most cases of amaurosis turns upon two points, viz.—the employment of ordinary antiphlogistic means, and letting these be quickly conjoined with, or followed up by, the use of mercury. Here it acts in the same way as it does in *iritis*; and, in order to give it a fair trial, the system must be kept under its influence for a month or six weeks. The influence should also be such as is indicated by a moderate degree of salivation. Perhaps, I may say, with respect to nine out of every ten cases of amaurosis, that, if they will not yield to a combination of antiphlogistic and mercurial treatment, they will yield to nothing that has yet been discovered.

You ought, indeed, to modify such treatment according to circumstances. Thus, if your patient were of weak frame, and apparently affected with more gastric than cerebral disorder, you would employ, perhaps, local bleed-

ing, rather than venesection; and moderate doses of the blue pill, or compound calomel pill, with saline medicines, in preference to the active exhibition of calomel, or the frequent use of mercurial ointment.

In some cases, you would avail yourselves of the assistance of counter-irritation, as a blister or seton applied to the nape of the neck or temple.

The plan of treating amaurotic eyes by stimulating them with electricity, or other applications, and by giving tonics at first, is found to be generally unsuccessful. The idea of amaurosis being connected with debility may be set down as most erroneous. The only exceptions to this remark may be the amaurosis from suckling, and from profuse loss of blood. If a delicate female were to lose, first, her health, and then become amaurotic from suckling a hearty child, of course the best plan would be to wean it, and give her tonics and a light nutritious diet, with a small quantity of wine daily.

The case termed *hemeralopia*, or *night blindness*, is an incomplete and periodical amaurosis, exemplifying also, according to my judgment, the reality of functional cases. The patient enjoys good vision all the day; but, after twilight, he becomes blind. No sooner, however, does the sun rise, than the affection of the optic nerve and retina goes off, and the patient then sees very well again. Now, gentlemen, unless you happen to be destined for the tropics, you are not likely to meet with any cases of *hemeralopia*; for, in this climate, they are rare, and, when they do occur, are only relapses in persons who have been previously affected in hot countries. This curious variety of amaurosis is easily cured by applying blisters to the temples, and having recourse to mild antiphlogistic treatment.

Nyctalopia, signifying blindness during the day and vision by night, is described by writers, but is so rare, that few surgeons have ever seen an example of it. Larrey records a case of it in an old man, one of the galley-slaves at Brest, who had been shut up in a dark subterranean dungeon for thirty-three years. When released he could only see in the shade of night, and was completely blind during the day. Ramazzini also mentions an epidemic day-blindness, which, in his time, attacked boys in Italy, about ten years of age. But, though we do not meet with *nyctalopia* in England as an original disease, you know very well, gentlemen, that great intolerance of daylight is one of the common effects of scrofulous ophthalmia. You must all likewise have heard of the *photophobia*, or aversion to light, exemplified in the *albino*. Day blindness is also noticed as a symptom of *mydriasis*, or a simple preternatural dilatation of the pupil. Patients with incipient cataracts, we know, see very little in the brightness of day, but much better in the evening, when the light is diminished and the pupil expanded.

A *Cataract*, gentlemen, is usually defined

to be a weakness, or interruption of sight, produced by opacity either of the crystalline lens, its capsule, or the fluid of Morgagni. Occasionally, however, the term is used in a more comprehensive sense, implying every perceptible obstacle to vision situated between the vitreous humour and the uvea and pupil.

When the disease is seated in the lens, its capsule, or the fluid of Morgagni, it is called *true cataract*; but, when it consists of opaque matter deposited in front of the lens, it is denominated a *false cataract*. You have, then, lenticular, capsular, and capsulo-lenticular cataracts. The Morgagnian may be dismissed from present consideration, its separate existence not being generally credited.

Cataracts are also distinguished into *idiopathic*, or such as arise from internal, but generally unknown, causes,—and into *accidental*, which originate from external violence, or active inflammation. In general, the idiopathic sooner or later affects both eyes; but an accidental cataract is frequently confined to the organ that has been injured.

The symptoms of a cataract are of the following description:—1st. All objects, especially white ones, seem to the patient as if covered with a mist, a circumstance that generally precedes any visible opacity behind the pupil. 2nd. The decline of vision bears an exact proportion to the degree of opacity. 3rd. The opacity is almost always first noticed in the centre of the pupil, the examples in which it first presents itself at the circumference being much less frequent. 4th. When the iris is light coloured, the more opaque the cataract is, the more plainly will you see a blackish ring at the edge of the pupil; and such a ring is particularly conspicuous when the cataract is soft and large, as it then propels the margin of the uvea forwards. 5th. As a cataract generally begins at the central point behind the pupil, such objects as are placed directly in front of the eye are most difficultly seen, even in the early stage of the disease; but those which are on one side may yet be discerned, particularly if the light be not strong, which would make the pupil too diminutive to let the rays pass through the thinner transparent edge of the lens. 6th. What I have just observed, gentlemen, will enable you to understand, why patients, having an opacity in the centre of the lens, are sometimes completely blind in a strong light, though they may enjoy a useful degree of vision in the shade, or in moderately dark places. 7th. The eyesight of patients affected with incipient cataract may be materially assisted with convex glasses, because objects are magnified by them. 8th. To patients in this state, the flame of a candle seems obscured in a white misty halo, which always becomes broader the further the patient is from the light. When the cataract is more advanced the flame cannot be discerned, but merely the place of the light. 9th. The mobility of the iris is not affected.

In amaurosis, the horn-like or glaucomatous

appearance is more deeply seated in the eye than the opacity of a cataract, and is somewhat concave. It is frequently of a greenish colour, while the opacity of cataract is usually greyish, white, or amber coloured. The decline of vision, also, is not in a ratio to the opacity, and the patient may be entirely blind, with little appearance of defect in the eye. The pupil is likewise generally dilated and motionless, with its pupillary margin somewhat irregular. The temporary increase or decrease of blindness, a circumstance so common in patients with incomplete amaurosis, depends upon circumstances, which depress or excite the system, and not, as in cases of cataract, upon the degree of light, and the corresponding alterations in the size of the pupil.

The misty halo seen by amaurotic patients round the flame of a candle is not like a whitish cloud, as in cases of cataract, but exhibits all the colours of the rainbow. To amaurotic patients spectacles are of no service; and objects situated on one side are not better seen by such persons, than those which are directly in front of the eye. Neither is there any temporary increase of the power of vision obtained by the use of belladonna, as in cataract.

Whiteness denotes either dissolved lens or a capsular cataract; a grey colour, a lenticular cataract; an amber colour, or dark grey, a firm lens; and light grey, a soft one. If the whole extent of the pupil is uniformly opaque, the cataract is probably one of the lens; if the opacity is streaked or speckled, it is likely to be one of the capsule. If the opaque streaks radiate from a centre, the posterior layer of the capsule is probably affected. If the form of the opacity is convex, either the anterior capsule or the lens is the seat of it; if concave, the posterior part of the capsule. With the light concentrated on the pupil by means of a double convex glass, all these particulars may be ascertained. I believe that the size of a cataract is a better criterion of its consistence than its colour is; and, at all events, gentlemen, you will generally find, that the smaller the lens is, and the darker its colour, the more solid its substance will be; while the larger and more protuberant it is against the iris, the greater is the probability of its being soft.

A cataract of the lens itself, as I have already explained, is termed a *lenticular cataract*, which may vary much in its consistence. Thus, such a cataract may be *hard*, as it is often found to be in elderly persons, with an amber colour, the tint being deeper in proportion as the cataract is firmer.

A lenticular cataract may be *soft*, that is to say, of a cheesy, gelatinous, or even milky consistence. Soft cataracts are more bulky than hard ones, so that they project nearly into the pupil. Hence, sight is more considerably interrupted than when the cataract is hard, and the power of distinguishing colours frequently quite abolished. The capsular cataract has a smooth and glistening surface, with

streaks upon it, and it lies close to the edge of the pupil.

When the lens is present, you rarely meet with a capsular cataract unaccompanied by a lenticular one; but an opaque lens may be removed, or taken away by absorption, and a capsular cataract may be left. In this case, as the opacity is merely a thin layer of the capsule, the cataract makes no projection against the iris, and the anterior chamber is not lessened by the advance of the iris towards the cornea.

Gentlemen, another fact worthy of your attention is, that you never have a hard cataract in a child. In adults you meet with both hard and soft ones; but, in young subjects, never with the hard kind.

Cataracts may occur in every period of life, and children are sometimes born with them, in which event they are termed *congenital*. They are most frequent, however, in elderly persons. In the generality of examples, the disease arises without any manifest cause, or any thing wrong in the state of the rest of the eye, or of the constitution at large. The capsulo-lenticular cataract is alleged to form very commonly under circumstances denoting a determination of blood to the head and the eye, accompanied by uneasy sensations in those parts; but generally we cannot refer the origin of a cataract to any particular causes. There is an exception with respect to cataracts following a wound of the lens, or its capsule. Experience proves that the slightest prick of these parts will lead to their opacity, or rather, I should say, that the capsule inflames, and becomes opaque, and the lens itself is afterwards absorbed, so that the result is, in fact, a capsular cataract.

A cataract is termed *simple* when accompanied by no other disease of the eye likely to impair its functions, or with no particular constitutional disease; *complicated*, when joined with other diseases of the eye, as adhesion of the crystalline capsule to the iris, amaurosis, or a gouty, rheumatic, or syphilitic state of the system.

Glaucoma and amaurosis are the worst complications. The circumstances denoting glaucoma have already been explained. If, in addition to a sluggish or immoveable iris, you find that the patient is totally incapable of distinguishing the least glimpse of light, you may certainly infer, that the cataract is combined with amaurosis.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XXI.

Painters' Colic—Effect of Metallic Poisons on the Nervous System—Nature of Neuroses—Symptoms of the Lead Colic—Abdominal and Cerebral Symptoms—Convulsions, Coma, Blindness—Paralysis—Slight Fatality of the Disease—Researches of Thomson on the Poison of Lead—Symptoms of the Disease in Animals—Effect on the Generative System—Similarity of the Symptoms to those of the Human Subject.

GENTLEMEN,—A great deal of our time has been already occupied with the diseases of the digestive system, in fact, much more than I originally intended; the only apology I have to make for this, is the deep and paramount importance of the subject. Before I quit this part of the course there are yet one or two subjects to which I shall briefly allude, namely, peritonitis and painters' colic. With respect to the first of these diseases I shall say but very little, the ordinary form of peritonitis is a disease so well known and so fully treated of in books, that it would be only a waste of time for me to go over it; and with respect to peritonitis from perforation, all the original information I could communicate on this part of the subject, may be seen in one of my published clinical lectures, and in the article on *peritonitis from perforation*, in the London Cyclopaedia of Practical Medicine. The ordinary form of peritonitis has been described in this work by Dr. M'Adam, the disease from perforation by myself. I shall therefore pass over this subject, and proceed to the consideration of a very interesting disease, painters' colic.

This disease is called painters' colic, from the circumstance of house-painters being extremely liable to it from coming into frequent contact with the poison of lead. Its synonyms are numerous, dry colic, Saturnine colic, rachialgia metallica, Devonshire colic, &c., &c.

Painters' colic is an example of the effects of a metallic poison on the nervous system. There are certain metals which produce a powerful effect on the system, not by means of their corrosive properties or by any direct action on the surface to which they are applied, but by a peculiar impression made upon the nervous system. Thus we find that mercury under certain circumstances will give rise to a very singular nervous disease; arsenic may be introduced into the system in such a way as to produce symptoms of nervous lesion; copper exercises a similar morbid influence, and the effects of lead are uni-

versally known. I do not mean to say that all these metals produce similar effects on the economy, for this is not the case, but there is one point of agreement between them, that all may produce symptoms which are called nervous or neurotic, and the diseases thus produced are classed among the neuroses. What is the meaning of this term neurosis? *A lesion of nervous function, more or less complete, occurring independently of any demonstrable organic change.* A neurosis, then, is an alteration in the functions of the nerves of organic and animal life, the nature of which alteration we cannot understand, neither can it be demonstrated by the knife, nor by any examination of the state of the nervous tissue. In other words, a person will die with the symptoms of a neurosis, and when you come to examine the body, you will be unable to detect, in the minute ramifications of the nerves, the trunks, or the nervous centres, any appreciable lesion.

Diseases of this description have been divided into two classes,—active and passive neuroses. Active neuroses signify an increase or exaltation in the nervous function; passive neuroses are those in which there is a diminution of nervous energy; in both there is an absence of perceptible organic change. Take, for instance, an example from the nerves of animal life: a case of convulsions, independent of organic disease, is an example of the active neurosis; a case of paralysis, under similar circumstances, is an example of the passive. In the former, there is an exaltation of the nervous function, which is reflected upon the muscular system; in the latter, there is a diminution, producing a partial or total loss of the power of motion. It has been asserted by eminent physiologists, that passive neurosis can only exist in the organs of the life of relation, because the functions of the ganglionic system, which presides over organic life, cease only at the death of the individual. But there may be such a thing as semi-paralysis of the organs to which the ganglionic nerves are distributed, and hence we may have passive neuroses of the system of organic as well as of animal life. We get a good idea of these neurotic affections, by taking some of the most remarkable instances of this kind. Hydrophobia is a remarkable instance of excessive lesion of the nervous function without any known organic change; so is tetanus, and so are some forms of apoplexy, convulsions, and mania. Here we have violent irritations of the nervous system, in which there is no perceptible organic change, and where the only information we derive from pathological anatomy is of a negative character, telling us what these diseases are not, and leaving us, as to their actual nature, as much in the dark as ever. We find by dissection that hydrophobia and tetanus, and hysteria, and convulsions, and apoplexy, are not caused by inflammation of the brain or spinal marrow,

and that is all. Hydrophobia, tetanus, convulsions, and hysteria, are instances of active neurosis; paralysis and apoplexy, without any known cerebral disease, are looked upon as examples of the passive kind, because they present either a diminution or abolition of the nervous function.

In the present state of medical science we must admit this division of the affections of the nervous system into diseases with and without perceptible organic lesion. I grant that it is very difficult, when we come to consider alterations in the functions of parts, to conceive how such changes could be effected without molecular alteration, or that the brain could be deranged in its functions, without some change of this kind. We are, however, compelled to consider such functional alterations of the nerves as changes with which we are unable to connect any process of hardening, or softening, or anomia, or congestion, or, in fact, any *known* pathological condition. Rostan is of opinion that all diseases are organic, that is to say, that they are produced by some molecular change, and this, he says, should be the basis of medicine. Unfortunately for medicine it has been given so many bases, that it sometimes knows not what leg to stand on.

But to return to our subject. Painters' colic is an example of a neurosis, that is to say, it is a lesion of the nervous function, unconnected with any known pathological alteration. It presents commonly two periods, the first exhibiting the phenomena of active, the second of passive, neurosis; or, in other words, the signs of exaltation of the nervous function precede those of depression. In the majority of cases, we find the first stage of this affection characterised by violent spasm, pain and convulsions, symptoms indicative of active nervous lesion, whereas in the second stage we have paralysis, the diagnostic mark of the passive kind. This is the order in which the phenomena of painters' colic are generally met with, but in some cases the first stage is either very imperfectly shadowed out, or even entirely wanting; the paralysis comes on in an insidious manner, and without being ushered in by any symptoms of exaltation of the nervous function.

In this country the most common victims to this disease are painters, who are much in the habit of working in white lead; and when you are connected with the management of any public medical institution (as I hope you will all be), you will often have to treat cases of this description. In Dublin and all large cities, it is an exceedingly common affection, and the patients are for the most part house-painters. Next to these, the persons who are most subject to it are plumbers, and those who are employed in the melting of lead.

When the poisonous particles of lead enter the system in a highly volatilised state, its morbid effects are more certain and extensive. Every house-painter will tell you that the kind of work which is most likely to produce

a deleterious effect, is painting "the *dead white*," or, as it has been termed, *statuary white*. In doing this they use white lead combined with a large proportion of oil of turpentine, and, in order to produce the intended effect, they are in the habit of excluding the air as much as possible. By means of the turpentine and the warm temperature of a close room, the lead is volatilised, and in this state appears to have an extraordinary power of impregnating the system. Some of the very worst cases of painters' colic are produced in this way. Painting in the open air, even where the same preparation is employed, is comparatively harmless. A poor fellow, who was for a considerable time under my care, assured me that he had escaped for twenty years, and was convinced that he would have enjoyed a much longer immunity, had he not been put to work at the statuary white in a close room.

With respect to plumbers, it is now ascertained that this disease is of comparatively rare occurrence among them, and the reason of this is that they generally work in the open air, or in well ventilated apartments, and have now but little to do with the actual manufacture of lead. The kind of lead which they generally use, sheet and pipe lead, is furnished from the manufactories, and their occupation principally consists in the moulding and soldering of it. We very seldom now see a plumber labouring under colic.

Painters' colic may be observed under a great variety of forms, but for the convenience of studying the disease, we may divide these varieties into four classes. In the first we have the phenomena of simple colic, without any obvious or marked symptoms of bilious, gastric, or cerebral derangement. In the second variety, the disease assumes a more decided character; the colic is complicated with symptoms of fever of a gastric character, the pain in the belly is more acute, the constipation more obstinate, there is pain and difficulty in going to stool, nausea and vomiting, with occasional headache, dyspnoea, and sense of constriction about the præcordia, the belly is hard and retracted, and there is often pain in passing urine. In the third variety we have a more formidable array of symptoms. The functions of the brain and spinal marrow are deranged, there are wandering pains in the extremities, and the patient has frequent attacks of violent convulsions, resembling those of epilepsy. He also labours under the abdominal symptoms, but in this stage they are not so well marked, or so distinct as in the former; the lesions of the functions of the cerebro-spinal system begin now to exhibit a greater degree of preponderance, and claim the principal share of the attention of a symptomatologist. In the fourth variety there is paralysis, without being preceded by the ordinary symptoms of abdominal or cerebral derangement. A medical friend of mine met with a case of this kind not long since. He

was called to visit a child who had lost the use of his limbs. He went and found the child lying in bed perfectly quiet and easy, his intellect sound, and his spirits good, but labouring under complete paralysis of all his limbs. He inquired minutely into the history of the case, and made a most scrutinising examination, but, from all he could see or learn, there was not the slightest ground to suspect disease of the brain or spinal cord. There had never been any symptoms of colic. He was puzzled with the case, and tried one thing after another without benefit. At length he found out that the child's father was a painter by trade, and this led him to suspect that the symptoms might have some connexion with the poison of lead. He inquired, and was told by the mother, that a quantity of white paint had latterly been kept in the room, and that it was impossible to keep the child from it. He instantly had the paint removed, a free current of air admitted into the room, and by the use of purgatives, assisted by stimulating frictions, the child recovered.

The following is the order of symptoms generally observed in this disease. First, we have the precursory, denoted by pain and sensation of weight about the epigastrium, a weak, small pulse, general languor and weakness of the muscular system, want of appetite, cold, clammy skin, a tremulous and coated tongue. At this period there is sometimes diarrhoea. Then comes some exciting cause, exposure to cold or wet, excess in eating or drinking, and the disease sets in with more or less intensity. The patient is attacked with dreadful pain in the belly, which differs from the pain of inflammation in this, that, so far from being increased by pressure, it is in most cases relieved. In fact, so decided is the relief produced in this way, that there is a case on record in which the patient used to get the greatest ease by making one of his fellow-workmen stand upon his belly. This relief from pressure is very generally observed in colicky affections. Indeed, so general is it, that you will hear it frequently stated, that all cases of colic are relieved by pressure. This, however, is not invariably true; for I have seen cases where the patients could not bear pressure, and where it required a careful examination to distinguish the symptoms from those of inflammation. The pain is of a twisting kind, and felt about the umbilicus; and, in connexion with this, there is scanty urine, with more or less pain in passing it, obstinate constipation, and a tense, hard, retracted state of the belly, from the violent contraction of its muscles. The upper portion of the belly is sometimes more retracted than the lower, and the pulsations of the abdominal aorta are unusually distinct. The pain remits, and then becomes exacerbated, and the patient's countenance is expressive of acute suffering. In that form of the disease, where there is a complication of gastric or bilious symptoms, the patient has a semi-

jaundiced look, a hot, moist skin, quick pulse, foul tongue, vomiting, hiccup, thirst, and epigastric tenderness.

In the third form, the chief force of the poison seems to be directed against the brain and spinal cord. There is vertigo, headach, stupor, and sometimes delirium; the patient has fits resembling those of epilepsy, but of longer duration, and violent convulsions, which sometimes continue with unabated intensity for twelve or even twenty-four hours. You will see those unfortunate creatures rolling and twisting in every form, sometimes doubled forwards, sometimes in a state of perfect opisthotonos, sometimes moving their limbs with the convulsive action of an epileptic, and foaming at the mouth. In addition to this, it is stated in the descriptions of this disease, that the patient loses his sight and becomes amaurotic; this I can confirm, for I have seen it more than once. It is a curious fact, too, that this blindness may come on before the other cerebral symptoms are developed. I recollect a case in which one of the first symptoms was blindness. The patient happened one evening to be indulging himself in whiskey punch, and was in a fair way of getting comfortably drunk, when, unfortunately, he found that all of a sudden he could see neither single nor double. He groped about in a very disconsolate state for his glass, but not finding it, and finding at the same time that he had lost his sight, he came to the hospital next morning, and shortly after his admission had a violent attack of convulsions. In cases of this kind I have generally found the pupils contracted. The patients toss about in bed, and are frequently found lying with their heads turned towards the foot of the bed. In some cases the breathing has been stertorous for a length of time, and the head fixed, but the fingers and hands were flexible. I have seen cases in which the coma disappeared, and was followed by perfect blindness, lasting for two or three days, and then yielding to treatment.

These symptoms, striking and extraordinary as they are, do not seem to depend on the same state of the brain as cases of other diseases which are accompanied by sanguineous determination to that organ. The reason I make this assertion is, that many of the most violent nervous symptoms, including profound coma, subside under the use of a stimulant treatment. I think we may look upon these symptoms as similar to what are termed the symptoms of the *nervous apoplexy* of the ancients. A case of this kind, which occurred in the Meath Hospital, is deserving of notice from the singular effect produced by treatment. The patient was in a state of profound coma, but the head was cool, and the arteries had no inordinate pulsation. If this was a case which presented the other symptoms of apoplexy, I would have prescribed bleeding, leeches, and cold applications. But I reasoned thus—Here is a case

in which there is no evidence of the existence of inflammatory action. Opium has been found to relieve the abdominal symptoms of the disease,—may it not also relieve the cerebral? I ordered the patient to have a free dose of laudanum in camphor mixture. In a few hours he awoke, sat up in his bed, and next morning we found the symptoms of coma had completely disappeared. In two other cases of a similar kind, I have given opium and carbonate of ammonia with the most favourable result.

Dr. Clutterbuck mentions a peculiar symptom of this disease,—a kind of gouty inflammation attacking the great toe and followed by relief. I have not seen this. He states that the first joint of the great toe becomes red, hot, painful, and swollen, and that this remits by day and returns again at night. I have never seen this, nor have I ever seen those hard tubercles on the tendons in various parts of the body, which some authors have described.

After these symptoms we come to a new class, namely, the passive, characterised by paralysis of the muscles of animal life. It is remarkable that this paralysis seems to be principally a paralysis of motion, and that the power of sensation is seldom or never impaired. Generally speaking, the upper are more subject to paralysis than the lower extremities, and the right than the left arm. The latter circumstance is explained by assuming that the direct influence of the poison is more applied to the right arm. The paralysis of the arm is also frequently partial; the extensors lose their power, but the flexors do not in so great a degree. You will see a patient with his arm hanging by his side as if it were dead, but if you give him anything to hold he can grasp it firmly. I have known painters continuing to work with a semi-paralysed arm. There is also an atrophied condition of the affected part, and this sometimes comes on with such rapidity, that, in the space of a week or ten days, the affected limb will be scarcely half as bulky as the corresponding one. We cannot account for this remarkable emaciation on the principle of loss of motion alone, for the short space of time in which it occurs in many instances is opposed to our entertaining such an opinion, and we must look for some other explanation. On this point science affords us no satisfactory information.

This disease, notwithstanding all its terrible array of symptoms, is very seldom fatal. Hence the uncertainty which long prevailed as to its pathological nature. In the great majority of cases, where a dissection was made, the patients died of some other disease, which either occurred during its course, or had preceded it. All that appears to be established at present is, that there is no known organic change of the nervous system connected with this disease, that it occurs in all its forms without the co-existence of organic lesion;

and that its exciting cause is the poison of lead.

It was formerly supposed that all the preparations of lead, whether applied externally or used internally, were capable of producing colic, but this doctrine is at present considered very questionable. It was thought that metallic lead and all its salts were capable of causing the disease, but the morbid influence of this metal is now restricted by the best chemists and pathologists chiefly to its carbonate. This opinion I believe was first put forward by Dr. A. T. Thomson, the author of the London Dispensatory, in an interesting paper published by him in the tenth volume of the Medico-Chirurgical Transactions. The object of this paper is to prove that, of all the preparations of lead employed in pharmaceutical and other purposes, the carbonate is that which is chiefly poisonous, and that the acetate and sub-acetate are comparatively harmless.

You have all, I am convinced, heard of cases of colic produced by the external use of the acetate of lead, and you will see some cases in proof of this opinion in Darwin's Zoonomia and other writings. There is a case on record of a woman, who having poulticed her ankle with this preparation, for the cure of a sprain, got colic and fell into a state of marasmus. I know of a deplorable case of burn affecting the abdominal integuments, which was treated with a solution of the acetate of lead. After using it for a fortnight or more, symptoms of colic came on, which not being recognised the lead wash was continued, and the woman died in great agony. Dr. Thomson explains all this in a very satisfactory way. He shows that the solution of acetate of lead, when exposed to the air, attracts a quantity of carbonic acid, and is thus converted into a carbonate; of this I have very little doubt, for you will find that, by exposing a solution of the acetate of lead to the full influence of the air, the carbonate will be gradually deposited in the shape of a white powder. In the same way we can understand why it is that a solution of the acetate of lead, added to fermenting poultices, may be converted into a carbonate by the carbonic acid which is evolved. It is also a fact, that the acetate can be used internally for a long time without producing any thing like deleterious effects. I have given it for weeks together in full doses without its having been ever followed by colic, or any symptoms characteristic of the absorption of a poisonous matter. There are cases on record where as much as six drachms of this salt have been taken internally without producing any sensible morbid effect. As far as my experience goes, all those cases, in which the medical use of the acetate of lead has been attended with disagreeable symptoms, were cases in which it had been used as an external application. There were two cases in the Meath Hospital in which this medicine was used externally, in which colic and other indications of poisonous absorption took place,

but not a single one in which its internal employment had been injurious. An excellent practical rule is laid down by Dr. Thomson, that, where you wish to employ the acetate of lead internally, you should take care to combine it with diluted acetic acid. Of the two combinations of lead with acetic acid, the sub-acetate is most liable to be decomposed and converted into a carbonate, so that, if you prevent this by mixing with the sub-acetate, or acetate, a certain quantity of distilled vinegar, there will be little or no chance of unpleasant symptoms being produced, even where the medicine is given in very considerable doses. We are, therefore, I think, justified in concluding that it is the carbonate of lead which is productive of poisonous effects, and that where bad symptoms have resulted from the use of the acetate it was in consequence of its being converted into a carbonate. I must, however, remark, that it has not been sufficiently proved as yet that the use of the acetate is *perfectly safe*.

It is an interesting fact, that many of the lower classes of animals are subject to this disease. Burserius was one of the first authors who directed the attention of medical men to this singular occurrence. I have got from my father an abstract of some observations made by him on this subject, during a visit to the lead hills in Scotland. He found that in the pastures among these hills, and in their immediate vicinity, cows, horses, sheep, dogs, and even poultry were subject to colic from lead. The symptoms, also, in these animals were observed by him to bear a very close analogy to those of the human subject. Thus, for instance, in cows there was obstinate constipation with suppression of urine, the poor animals seemed to suffer from violent twisting pain of the belly, and sometimes were thrown into a state of furious excitement, running wildly across the country. He learned also that during that period it was calculated that at least one-tenth of the cows in this situation had died of the effects of the poisonous absorption of lead. One of the most ordinary precursory symptoms was the animal becoming what is called hide-bound, this was followed by obstinate costiveness, and there was much apparent suffering, with panting, starting, and slaving from the mouth. Where the cerebral symptoms were most prominent the signs of abdominal irritation were by no means distinct, and this, as I have remarked, is the case in the human subject. In some, who had the head affected and ran wildly through the country, the secretion of milk was stopped, and this accords too with the effect of lead on the human female. Another remarkable circumstance is, that animals, living in the vicinity of these lead hills, have exceedingly difficult labours. Sheep are subject to epileptic convulsions and paralysis; dogs have the head principally affected, they run across the country slaving at the mouth, as if in a state of hydrophobia, but they do not bite, and are in

all respects perfectly harmless. In barn-door fowl the generative function was injured, and the hens reared or brought there ceased to lay eggs.

There is one fact mentioned in these observations, which tends to confirm the opinion of Dr. A. T. Thomson, that the poisonous effects of lead are produced chiefly by the carbonate. A distance of very few miles from the valley renders animals quite free from any liability to the disease, but if they should happen to stray into the immediate neighbourhood, and particularly into a portion of low ground, flooded during the winter months by a river, which runs along the valley from the mines, and which, in all probability, leaves behind an efflorescence of the carbonate of lead, they are very liable to be affected with colic. It is said, also, that the poison is produced by the volatilisation of lead in the smelting houses, the vapours of which are carried down the valley and through the neighbouring parts. Be this as it may, the Gaelic name of the valley signifies, the *poisonous vale*, and, as it is very probable that this name had been given in consequence of the deleterious qualities of the place long before the establishment of lead works, it tends strongly to favour the opinion that it is the water which contains the poison.

The mode of cure employed by the shepherds in this place is to give strong purgative injections, and remove the cattle from the influence of the poison, by sending them to new and healthy pastures. In this way they frequently recover, and if we look to the cause of the disease, its symptoms, or mode of cure, we shall observe a striking analogy between it and the colic from lead in the human subject. I shall conclude this subject at my next lecture, and then go on to diseases of the chest.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS AND CHILDREN,

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE XVIII.

Comparative Mortality among Infants in ancient and modern times—Evils and benefits of Foundling Hospitals—Mortality of Infants in different countries.

GENTLEMEN,—Among the numerous discoveries in medicine, there is nothing which can be more pleasing to the physician and the philanthropist, than the great diminution in the mortality of children. The vast destruction of infants excited the attention of many illustrious philosophers of different ages, whose opinions finally triumphed over ignorance and prejudices, and whose precepts have so materially protected human life. Besides the

numerous writers on the management and diseases of children already quoted, there are a few among the moderns, who eminently deserve honourable mention—Dr. Watt, of Glasgow, Sir Gilbert Blane, Bart., Dr. Underwood, Dr. John Clarke, Mr. Milne, Dr. Caspar, M.M. Gardien, Leroy, Capuron, and Villermé, Mr. Robertson, of Manchester, and Dr. Bisset Hawkins.

These remarks having been premised, I shall now proceed to give an account of the comparative mortality among infants in ancient and modern times.

In ancient ages it was a custom in many nations to destroy all delicate infants. The barbarous and unnatural crime of infanticide was common until the establishment of Christianity, which taught that every human being, whether strong or weak, was a fellow-creature, an heir to the same high destiny, and entitled to care, protection, and support. Infanticide could not exist under this unequalled system of religion, and wherever it extended its benign influence, the destruction of human life was no longer allowable. In pagan countries the most revolting modes of child murder were practised. The ancient Persians buried their weak and delicate offspring alive. The laws of many of the Grecian states enforced infanticide, as it was held that the number of children should be limited, and that those who arrived at the adult age might not produce degenerate citizens. The ancient Carthaginians, Phœnicians, and Chinese, were notorious for the barbarous treatment and murder of their children. This horrible practice prevailed within a recent period in India, until abolished by the Marquis Wellesley, Mr. Duncan, and Colonel Walker. It is stated by a modern writer, that in the provinces of Cutch and Guzerat 3000 children were sacrificed annually.—(Buchanan's Researches in Asia.)

As civilisation advanced, asylums were established for the sick poor, for lying-in women, and for foundlings, and these have most materially diminished the mortality of infants, as will appear by the statistical reports I shall submit to your consideration.

I cannot at all agree with Malthus, Beck, Hawkins, Robertson, and others, that the utility of foundling hospitals "under any system of indiscriminate admission, is highly questionable. It will presently be seen that they have done very little towards the preservation of infant life; and it is certain that the facilities which they afford corrupt maternal instinct, and offer a premium to seduction. Altogether we have reason to congratulate ourselves that England contains so few, and that the only one in Great Britain (of whose existence we are aware) subsists under limits which counteract abuses.

"The Foundling Hospital of London deserves priority of mention, not merely on account of its excellent economy, and the good health of its inmates, but from its standing

alone in the principle of rejecting secret or indiscriminate entries. It acted originally on the same system as other foundling hospitals, but has happily changed it, to introduce examination of the mother's previous character, and a special application on her part. So far is this difficulty from encouraging infanticide, that the crime is rare in London; and far from being unfavourable to the preservation of infants, in scarcely any situation is their death so probable as in the hospitals where they are admitted clandestinely."—(Hawkins, Elements of Medical Statistics.)

Now, it appears to me that of all our charitable institutions there are none more humane than foundling hospitals, which afford protection and care to helpless infants, and show a benevolent tenderness towards the feelings of those distressed creatures who are compelled by poverty or by shame to avail themselves of the benefits of such institutions for their offspring. At the Paris hospital, no observation is made, no impertinent or unfeeling question is asked; the infants are received in silence, are reared with care to maturity, and provided for, unless circumstances enable the parents to claim them, when they are cheerfully restored. Such asylums prevent infanticide, and I may mention a corroborative circumstance, that so frequent was this crime some years ago in Dublin, near the site of the Foundling Hospital, before the erection of that institution, that the place was called "Murderer's Lane." Now the crime of child murder is seldom heard of in the Irish metropolis, because all children presented at the hospital, whether born in the city or in the country, are received without any questions being asked. The indiscriminate admission of infants is therefore a blessing and not an evil, and is an effectual preventive to the unnatural crime of infanticide. Here, then, is a positive proof of the justness of my opinion.

The indiscriminate admission of illegitimate or abandoned children into foundling hospitals, does not appear to me to be so highly questionable as the above authors imagine. Religion and humanity are opposed to the sacrifice of human life; and the admirable spirit of Christianity, which led to the establishment of such institutions in most civilised countries, is a proof of the validity of my conclusion. I should like to be informed what would become of illegitimate children in those countries where there are no poor laws for their support, and, in reality, for the encouragement of immorality, were there not indiscriminate admissions into foundling hospitals? In France and Ireland where there are no poor laws, there are indiscriminate admissions, and it remains to be proved whether the crime of infanticide is more common in either of these countries than in this; nor is the number of illegitimate children greater, nor, in the opinion of many, so great. In this section of the nation there is not indiscriminate admission into the

Foundling Hospital, but there is indiscriminate support allowed by the poor laws, "and it is certain that the facilities, which they afford, corrupt maternal instinct, and offer a premium to seduction." It cannot be denied that any man in this part of the kingdom, of whatever rank or calling, may have an order of affiliation awarded against him, on the oath of the most abandoned and profligate female, though it is proved by several witnesses, that she might have more properly accused any one of many individuals. Is this not offering as great a premium to immorality as foundling hospitals?

I therefore cannot perceive, so far as morality is concerned, that we have just reason to congratulate ourselves on having so few foundling hospitals, or on "the Foundling Hospital of London standing alone in the principle of rejecting secret or indiscriminate entries." There is no occasion for either, as both are encouraged to the fullest extent by our poor laws. Neither is there the slightest necessity "for examination of the mother's previous character" at the police offices. If there is not indiscriminate admission of infants at the Foundling Hospital of London, there is indiscriminate protection afforded to them, by the reputed fathers, or workhouses and parishes, and a preponderating majority of mothers will, from natural affection, prefer rearing their children, when allowed the means of support, to parting with them for the advantages of any asylum. In Ireland where there is no means of support afforded by law to the poor, maternal affection must yield to dire necessity; and the children of the indigent, as well as those that are illegitimate or abandoned, are indiscriminately received at the Foundling Hospital, sooner than allowed to perish, with the charitable intention of preventing the abandonment of infants, and the unnatural crime of infanticide, which is rarely heard of in that part of the United Kingdom. I am gratified to admit that child-murder is rare, or, to speak more correctly, comparatively rare in London; but the reason is that there is no motive to lead to its commission, except shame, which is, perhaps, equally powerful in all civilised countries. Lastly, I very much question whether the mortality is equal or greater in foundling hospitals in which there is indiscriminate admissions, than in those in which there is not. It is not fair to draw conclusions from the mortality in institutions which are managed so differently. In some the offspring of the most diseased and profligate are admitted, while in others those only of moral individuals. As to the mortality in such establishments, compared to that of society, I believe there is, in general, very little if any difference. It appears by the result of an investigation made by Dr. Coombe at the British Lying-in Hospital, and published by Dr. Underwood, that several women who had borne three children had lost two; those who had four, three; five, four; six, five; seven, six; eight, seven; nine, eight; ten, nine;

eleven, eight and ten; twelve, ten and eleven; fourteen, eleven; and several of the mothers of the different numbers had lost them all. Dr. Merriman instituted a similar inquiry at the Westminster General Dispensary, and the result was similar; and he adds, "there was scarcely an instance of any woman who had preserved all her children, if she had borne more than three." The cause of this immense mortality is mismanagement of diet, clothing, &c., as already described under the head of *Etiology of Infantile Diseases*. The mortality is much less in foundling hospitals, as will appear hereafter.

It is impossible to ascertain the absolute mortality in London and Westminster, where imperfect registries are preserved; as, according to Mr. Rickman, the compiler of the *Population Returns*, there is a deficiency of 8000 burials annually, on account of the exclusion of dissenters, who are interred in cemeteries of their own, of whom no account is given by the worshipful company of parish clerks. The comparative mortality can only be supposed from imperfect data.

The defect of accurate bills of mortality is about to be remedied by an act now before Parliament (May, 1834), for an accurate registry of all the births, marriages, and deaths, in England and Wales; and a General Statistical Society has lately been formed in London for the same object.

Though the existing records are imperfect, yet it is pleasing to observe that the mortality of infants and children is wonderfully diminished during the last century, and that the general mortality is very nearly the same in all parts of Europe. This fact clearly establishes the inference, that the practice of the healing art is not so different in this kingdom and continental nations as has been too generally supposed.

I shall now refer to the bills of mortality, inaccurate as they avowedly are, in proof of the preceding statements.

On referring to a table of the bills of mortality for forty years, from 1760 to 1799, inclusive, taken from the *Annual Register*, the number of burials was 836,285 of subjects, of which 281,408 died before they attained two years of age, and 113,393 died before they reached the age of ten years. According to this account, nearly a fourth die under two years of age, and of the survivors about a fifth in the succeeding eight years. The mortality in the British Lying-in Hospital, London, in 1750, was 1 in 15; in 1780, 1 in 44; and from 1789 to 1798, 1 in 77. In Paris, in 1750, the deaths were 1 in 15. In the Edinburgh Lying-in Hospital, from Sep. 26, 1826, to Sep. 29, 1828, there were born 289 males, and 281 females, of which 12 died and 29 were still-born. In Prussia, the still-births are 1 in 32, and in Hanover about 1 in 30.

In 1780, the deaths between the age of five and ten years at Warrington, Chester, and Carlisle, in 10,000 inhabitants, were 14½, 13,

and 12, omitting small fractions. In the Blue-coat Hospital of Manchester, the deaths between 6 and 14 years of age were 1 in 520, annually. At the Ackworth School, superintended by the Society of Friends, the mortality was 1 in 400, annually. It is a remarkable fact, the Ackworth Foundling Hospital was attended by Dr. Buchan, who, in his "*Domestic Medicine*," and another work, was chiefly instrumental in eradicating the prejudices and anile errors in the management of the rearing of children. Humanity is very deeply indebted to him, though he is seldom, scarcely ever, quoted in this country; while he is considered entitled to great praise by the best French and German authors on the physical education of children. He however attempt an impossibility when he professed to make medicine no mystery.

According to Dr. Casper, of Berlin, the proportion of still-born infants in London and Vienna is 1 in 24, Paris and Dresden 1 in 19, Hamburg 1 in 15. (*Beiträge, &c.*) It is scarcely necessary to observe, that the proportion of still-births and abortions is greatest among unmarried women. Such infants are the fruits of vicious generation and of miserable, dispirited mothers.

The mortality in Paris was very great from 1771 to 1777; of 39,951 infants, 21,985 died during the first month, 3491 during the remainder of the first year, and at the end of 1777 only 4711 were alive. From 1789 to 1813, 109,650 were admitted into the Foundling Hospital, and only 39,330 died. (*Foderé.*) From 1786 to 1789 the mortality amongst infants in Paris was, according to Gardien, 90 in 100; and since the year 11 (1805) to the year 13 (1807), 64 in 100. The mortality at Vienna, in 1806, was 61 in 100, and in 1807, 58 in 100.

In the Foundling Hospital of Vienna from 1783 to 1793, the mortality was 1 in 2 before the fifth year, and in 1810, 1 in 4½.

At Stockholm, in 1822, 525 infants were admitted, of which 101 died—about 19½ per cent; 15 died the first month, 6 the second, 19 the third, 15 the fourth, 10 the fifth, and 3 the seventh.

At the Petersburg Foundling Hospital in 1787, the admissions were, on an average, 10 a-day, the deaths 100 a month, or 3650 admissions and 1,200 deaths.

In the hospital at Moscow, for twenty years subsequent to 1786, 37,000 infants were received, of whom 35,000 died. In 1811 the admissions were 2517, the deaths 1033. In 1812, the admissions were 2699, deaths 1348. (*Hermann. Mem. de l'Acad. des Sciences de Petersbourg. T. ix. 1824.*)

At Archangel, in 1812, the foundlings were 417, the deaths 377.

In Spain, the mortality among infants and children far exceeds the proportion of births.

At Lisbon, one birth in three is illegitimate, and at Oporto one in two.

The mortality at Florence is 1 in 10, at

Naples, 1 in 5, at Palermo 72 in 100. (*Bulletino Universali di Scienze, &c.* No. 52. 1825.)

In Paris, the number of foundlings admitted in 1829 was 1000: of these 251 died within the first few days, 235 on the road to the nurses in the country, and, at the end of the first year, only one half were alive.

The mortality in the London Foundling Hospital, for twenty years ending in 1827, from the period of admission to the age of 14 years, was 25 per cent. (*Hawkins on Medical Statistics, 1829.*)

During twenty-one years ending in 1796, 10,272 children were admitted into the Infirmary of the Dublin Foundling Hospital, and 45 only recovered. Of the gross number 1,201 were affected with syphilis; but, of late years, no more than 1 in 30 labour under that disease. This mortality led to a parliamentary inquiry; a new system of management was introduced; and wet-nurses were employed instead of dry-nursing or spoon-diet. From June 1805 to June 1806, 2168 infants were admitted, and the deaths were only 486. From 1800 to 1811 the number presented by distressed parents was 11,111, and 14,974 abandoned infants were received.

The number of abandoned children in Paris in 1827 was 8081. (*Annuaire pour l'An, 1829.*)

The mortality in the Dublin Foundling Hospital from 1781 to 1791 was immense, and would appear incredible had it not been attested by the records of the Irish House of Commons for the latter year. During this period of ten years 19,420 were admitted, of whom 17,120 were dead or unaccounted for; and that of 2180 admitted during the year 1790, only 187 were then alive. In a statement of a committee of the same house, reported May 8th, 1797, that within the quarter ending the 25th of the preceding March, 540 children were admitted into the hospital, of whom 450 died. That from the 25th March to the 13th April (nineteen days), 116 infants were admitted, of which number 112 died. That within the last six years 12,786 children were admitted, of whom 12,651 died, leaving 135 alive. In the Princely Hospital of Vienna about one in nineteen were preserved. In Moscow, 37,607 children were admitted in the course of twenty years—only 1020 were sent out. The mortality in the London work-houses used to be equally great.

In the year 1827, the Parisian Foundling Hospital was said to be in the most efficient operation. On these statements, Mr. Robertson, of Manchester, from whose work they are cited, observes,—“No perversion of benevolence was ever half so monstrous as the support of such establishments. They are a disgrace to any country; and, by the licentiousness which they foster, inflict upon it a just and fearful punishment.”

This sweeping condemnation of Foundling Hospitals appears to me to be unjust. The mortality arose from mismanagement, want of

parental care, dry-nursing, small-pox, and many other causes which no longer exist. It has been shown in the preceding account of the mortality of children, that the deaths are comparatively few in Foundling Hospitals at present, in consequence of the better management of physical education, the employment of wet-nurses, the abandonment of hand-feeding, the superior ventilation and cleanliness of the institutions referred to, and many other changes founded on reason and science.

It is worthy of remark that the Dublin is the only Foundling Hospital in the United Kingdom, which receives any infant, abandoned or left at its doors, without inquiry. In 1815, it was thus spoken of by Dr. John Clarke. “All newly-born children on being presented are indiscriminately admitted, without any recommendation, and are often then in a dying state. When this is not the case, the infants are sent into the country to be nursed with no superintendence, so that the diseases of early infancy cannot be observed. The writer has great pleasure in bearing his testimony to the neatness, cleanliness, good order, and general arrangement of the Foundling Hospital in Dublin.”

The number of children in the Foundling Hospital of London is generally about 310, and 130 in the country. They are received at any age under twelve months, and are immediately sent to wet-nurses in the neighbouring counties. The nurses receive a premium on rearing the children to a certain age, and when ill they have regular medical attendance. The children remain five years in the country, are educated on their return, and supported in the Hospital until the age of fourteen or fifteen, when they are apprenticed or sent to service. Their appearance is healthful, and, during a period of twenty years to December 1827, the mortality from the period of admission to fourteen years of age was twenty-five per cent.—(*Dr. Hawkins, op. cit.*) Children are not admitted without inquiry into the condition of their parents, and those that are illegitimate are supported by the parishes or poor laws, which do not exist in Ireland. Hence the numerical difference between the London and Dublin Foundling Hospitals.

Mr. Robertson, of Manchester, in his valuable work on the Mortality and Physical Management of Children, published in 1828, gives an account of the Manchester Lying-In Hospital from April 1821 to 1825. During that period 2056 children died under the age of ten years, and of these 994 died in the first year,—of convulsions 332, of measles 299, infantile decline 260, small-pox 187, dentition 181, inflammation of the lungs 155, hooping-cough 150, water in the head 125, bowel complaints 85, croup 41, inflammation of the bowels 38, white swelling 33, cholera 21, consumption 18, fits 18, worm-fever 11, scarlatina 8, &c. I omit the diseases which were few in number.

494 Dr. Ryan's Lectures.—Mortality among Infants at different Ages.

He gives another accurate table, showing that of the above number—

146	died under 1 month
116	between 1 and 2
74	2 and 3
201	3 and 6
218	6 and 9
193	9 and 12
501	1 and 2 years
246	2 and 3
210	3 and 5
157	5 and 10

The mortality in Paris in 1828 was—889 boys and 852 girls died of convulsions, the greatest number in the first three months of life, and from the first to the fourth year; of dentition, 154 boys and 161 girls; of measles, 120 boys and 202 girls; of small-pox, 85 boys and 35 girls; of hooping-cough, 78 boys and 82 girls; of croup, 77 boys and 75 girls. The infants born dead or prematurely were 682 boys and 564 girls*; and those that died during the first three months were 215 boys and 298 girls.—(Rapport par le Conseil de Salubrite.)

The number of infants admitted in Paris in 1829 was 1000, of which 251 died within the first few days, and 235 more on the road to the nurses in the country. At the end of the first year one half only remained alive.

It appears that from 1815 to 1822, the number of foundlings admitted into the Belgian Hospitals was 3,080. In 1832 there were in the Province of Hainault alone 1,870, in that of Brabant 2,244; and in 1833 the total for the whole kingdom gives the enormous increase of 6,968 foundlings, and 2,337 abandoned infants, making 9,805, three times the average periods of Dutch dominion. The late revolution affords a sufficient explanation of the increase, as it is a well-known fact, that the number of illegitimate infants is much greater in every country after a civil war. This was often observed, as will appear from subsequent statements.

There is no Foundling Hospital in Edinburgh, as the opinion is maintained in that city, that such an institution would be injurious to morality. There are, however, two public institutions for the admission of boys from the age of seven to fourteen, Heriot's and Watson's Hospitals. The mortality in the first, from 1811 to 1829, was 1 in 235, and in the other 1 in 123.4. In the Orphan Hospital, which contains boys and girls, the deaths from 1815 to 1823, were in the proportion of 1 in 37.5.—(Edin. Med. and Surg. Journal, 1828, v. xxix.)

In Glasgow, from 1782 to 1788, the average annual mortality was one in 26.7, and of the deaths 53.48 per cent. were of children under ten; that is among every 1000 of the population there died annually 87.45, of whom

20.03 were under ten. From 1807 to 1819 the annual mortality was 1 in 40.8, and of deaths 55.43 per cent. were under ten; that is in every 1000 inhabitants 24.51 died annually, of whom 13.58 were under ten, so that the mortality among children had decreased, in the latter periods, two-thirds.

The mortality which occurs in the first months of life, according to Mr. Robertson, is the following:—In the Dublin Lying-in Hospital 1 infant in about 6½ die under 15 days old. In the Westminster Lying-in Hospital the mortality was less; of 1,400 infants 1 in 16 died before the end of two months*. In the Manchester Workhouse of 347, 53, or two-thirteenths died before the 35th day; under 8 days 22; in the next 7 days 10; from the 14th to the 22nd day 7; from the 22nd to the 29th 7; and 7 more by the 35th day.

Of 3894 deaths under the age of ten years, taken from the Chester, Northampton, and Warrington mortality bills, 400 died under 1 month.

218	between 1 and 2
139	2 3
282	3 6
317	6 9
347	9 12

1,303

Dr. Underwood states that of 2,785 infants, who died during the first month, 1292, more than 46 in 100, expired the first day.

The following summary of all Mr. Robertson's tables shows the mortality at the different ages, under 10 years, in cities, smaller towns, village parishes, and agricultural parishes:—

1st. Cities and Large Towns.

	Under 2	2 & 5	5 & 10	Total under 10.
London . . .	35.12	11.88	4.89	51.93
Liverpool . .				
Glasgow . .				
Manchester .				

2nd. Smaller Towns and Cities.

Chester . . .	31.49	10.83	4.65	46.97
Carlisle . . .				
Warrington				
Northampton				

3rd. Village Parishes.

Spalding . .	35.36	7.01	3.54	45.90
Lynn				
Eccles				

4th. Agricultural Parishes.

Winwick . .	24.37	6.99	4.04	35.40
Grappenhall				
Grt. Shefford				
Ackworth . .				
Holy Cross .				

Grand Average	31.58	9.18	4.15	44.91
Total				

* See Clarke and Bland's Reports Phil. Trans. vol. 71-76. As these reports were made many years ago, and indeed many others cannot be relied on.

* Dr. Clark, of Dublin, has found the male head a little larger than that of the female.

: According to Susmilch's German tables the mortality is 43 per cent. for the country, 47.7 for small towns, and 50.2 for large cities. In France, according to Duvillard, it is 44.89 on the average of the kingdom. In England, for ten years before 1811, there died annually 1 in 47.30. In Wales 1 in 58.57.—(Milne on Annuities).

**A CASE OF FATAL EFFUSION OF BLOOD
INTO THE PERICARDIUM, WITH
DISSECTION.**

BY JAMES CARSON, M.D., LIVERPOOL.

THE following case of a disease which is of rare occurrence, which is obscurely marked by the accompanying symptoms, and which can scarcely fail to produce unusual excitement by the unexpected fatal termination, seems highly deserving of being recorded.

Mr. W., a gentleman about 52 years of age, of a tall and robust form, clear complexion, subject occasionally to dyspeptic affections, though of very regular and temperate habits; of an active disposition, though his occupation was sedentary and confining; had been for twelve months affected with considerable anxiety of mind, in consequence of the doubtful issue of some building speculations. Towards the end of Lent, which he had rigidly observed according to the injunctions of the Catholic church, on 11th of March, a day exempted from the prohibitions respecting diet, he had eaten freely of beef-steaks with onion sauce. He was, at that meal, sparing as usual in the use of wine. On the evening of the following day he was engaged, in a fatiguing and rather anxious way, with the business of a club, of which he was treasurer. On his return from the club, about 11 o'clock at night, in company with two of his friends, when he had nearly reached his own house, he was seized with faintness and debility to such a degree, that without the assistance of the friends who accompanied him he would not have been able to have kept his feet. Soon after his arrival at his house he was visited by Mr. Bromilow, his medical attendant. He described himself as faint and exhausted; complained of an obtuse, heavy pain at the præcordia, and was affected with flatulent eructations. His respiration was free, his pulse 70, and regular, though weak. He had no affection of the head, or pain anywhere, excepting as described in the chest. His bowels had

been opened that day. Mr. Bromilow ordered an antispasmodic draught, and left him with directions to take something warm and go to bed. He took the draught, and a weak glass of brandy and water. At three o'clock he sent for Mr. B. again, and, as the pain in the chest was not abated, he expressed a wish to be bled, which Mr. B. agreed to, more with the hope of satisfying his mind than from any great necessity for that measure being indicated by the symptoms. He lost a pint of blood. An opiate was then administered. At this visit Mr. B. examined the chest more minutely; he applied his ear to the different regions of the naked chest, but perceiving no unusual sound, or vibrations, concluded that the heart, lungs, and large vessels were in a sound state. At five o'clock A.M. I visited him; he felt cold, perspired gently, and chiefly complained of pain in the chest, which he described as wearisome and oppressive. It was not increased by taking a full inspiration. He had vomited a little in the course of the night, and had discharged some of the onion sauce he had taken the day preceding the attack. He was much troubled with flatulency, and belched frequently, but was not relieved by it so far as regarded the pain in the chest. His pulse was regular, the heat of the body natural, and respiration good. He had had no sleep.

From the information given by Mr. Bromilow, connected with my own observation, I considered that nothing could be indicated by the symptoms beyond an affection of the stomach, which is known to exhibit itself in such anomalous forms. He took four grains of calomel, and two of opium. We visited him again at half after eleven o'clock. He had had little sleep. The symptoms remained the same. He was ordered an aperient mixture, and we proposed to visit him again at seven o'clock. At this visit I replied to the anxious inquiries of the family—that we did not see any cause for alarm; that the complaint seemed to arise from indigestion; and that I had no doubt he would recover. At three o'clock in the afternoon he sent for Mr. Bromilow, as the pain still continued unabated, and wished to know if he might have anything to rub the part with. The bowels had not been opened, and he had had little or no sleep. A short time before seven o'clock, the hour at which we had proposed to visit him, and at which I was

prevented from attendance by an urgent call to a distant part of the country, Mr. W. was seized with what the family conceived to be a fit; and, a short time after the arrival of Mr. Bromilow, expired. In consequence of my unavoidable absence, other physicians were called in, and two arrived, but not until after the death of the patient. I applied for permission to open the body, which was granted. The body was examined twenty-four hours after death, by Mr. Bromilow, in my presence, and in that of my son, Dr. Carson, jun. The following were the appearances on dissection. Upon opening the chest, the lungs on both sides were perfectly sound and collapsed. But, notwithstanding the collapse, the chest was filled more than it usually is, when the lungs are sound. This indicated the existence of some foreign substance, or morbid enlargement of some of the organs. The pericardium was found accordingly to be immensely distended by some fluid, which, when this bag was opened, was found to be blood, partly liquid and partly coagulated: the quantity was not less than three pints. It was purely blood, without the admixture of any fluid indicating inflammatory action. The external surface of the heart, and internal surface of the pericardium, were examined carefully, but no ruptured vessels, from which the blood might have flowed, were discoverable on either of these surfaces. The heart itself was perfectly sound, the valves were in good condition, and no disease existed in any of the large vessels. The lungs were free from adhesions, and were every where sound. The other viscera were in a sound state. A great deal of care and time were expended in trying to discover the source from which the blood had flowed into the pericardium, but in vain: a slight ecchymosis was observed about the root of the pulmonary artery. Dr. Baillie, in his *Morbid Anatomy*, says, "Cases have occurred, though very rarely, in which a large quantity of blood has been accumulated in the cavity of the pericardium, but where no rupture could be discovered after the most diligent search, either in the heart itself, or in any of its vessels. This appears very wonderful, and not at all what any person would expect *à priori*. Two conjectures have occurred to me, to explain this phenomenon: 1st, that the blood-vessels on the surface of the heart have

lost their compactness of tissue, so that the blood may have escaped by transudation. The other is, that the blood may have been poured out by the extremities of the small vessels, opening on the surface of that part chiefly of the pericardium forming the immediate cover of the heart, from their orifices having been to a very uncommon degree relaxed."

There is a case related by Dr. Alston, in the 6th vol. of the *Edinburgh Medical Essays*, in which the disease of the chest was of long standing. Three pints of blood, which was partly coagulated and partly mixed with lymph, were found in the pericardium. No ruptured vessel was discovered either on the outer surface of the heart, or the inner surface of the pericardium. Upon pressing the heart a bloody serum oozed out of a great many orifices on its surface, and principally near its base. No disease was discovered in the interior of the heart or large vessels. Dr. Baillie refers to two cases of extravasation of blood into the cavity of the pericardium, in which the source of the hæmorrhage could not, after the most careful examination, be discovered. In both these functional disease of the heart had been observed for some time previous to the death of the patient.—*Vide Medical Observer*, vol. x. p. 330. *Memoirs of Medical Society*, vol. i. p. 238.

Various opinions have been advanced respecting the sources from which, in the above cases, the blood was derived. One of the suppositions made by Dr. Baillie appears to me to approach the nearest to the truth, which is, that the blood had oozed out of the small vessels on the internal surface of the pericardium immediately covering the heart. It is probable, I think, that the oozing, particularly in the case now narrated, arose from the condition of the blood, and the relaxed state of the fibres. It would appear that the disease was general, and that the shivering, faintness, and depression of spirits were not the effects of the flow of blood into the pericardium, but that this last was, like the affections stated, the effect or symptom of the general disease,—that in fact there existed a morbid state of the whole system, similar to that which takes place in purpura, in some kinds of epistaxis, hæmatemesis, and in bleeding from the bowels in typhus fever. The pain in the chest was, in the first place, occasioned by the admission of

blood into a cavity not accustomed to the stimulus of that fluid. There is no reason to suppose that the action of the heart would be mechanically affected until the quantity of the blood was pretty considerable; for the blood would readily follow the dilatation of the pericardium, occasioned by the elasticity of the lungs, when the chambers of the heart had finished their contractions. No sound was perceived on carefully examining the chest. Indeed no sound could be excited, as no fluid was poured from one vessel into another. For as the auricles expand, as the ventricles contract, the change of place in the constituents of the fluid in the pericardium would be inconsiderable, and made with quietness.

There does not appear to be any symptom in this case that would have warranted the medical attendants in giving an unfavourable prognosis. As a matter of prudence, a less favourable one might have been made, but the same prudence would not permit the expression of a favourable prognosis in any case whatever.—*Liverpool Medical Journal.*

A CASE OF HYDROPHOBIA.

BY D. MACRODIE, M.D.,

Physician to the Liverpool Workhouse and Fever Hospital.

On the morning of the 1st instant, I was called out of bed to visit Mrs. S., of lymphatic nervous temperament, who had been supposed to be dying in the night. She complained chiefly of a difficulty in swallowing, with a sense of straitness, or closing up, of her throat. Her pulse at first was numbered at 130 to 140, and speedily became pretty steady at 120; respiration irregular, and interrupted at times with a sort of shudder, or sigh; tongue covered, chiefly in the centre and towards the basis, with an ash-coloured mucous coating; bowels had been moved two or three times in the course of the preceding day and night; she had thirst, but was afraid to drink; skin not warmer than natural; countenance expressive of anxiety and suspicion, with the eyes somewhat suffused, and constantly moving from one object to another. Said there was an unusual beating at her breast; and replied to inquiry, that she heard at times the sound as if of bells in her ears. She had slept little or none for three or four

nights and days. On her daughter asking her to let me see her drink, she replied, that *she* could, as well as herself, show me the way, and declined. Finding that the family medical man had been in attendance for two or three days, I said, that his residence being but very little out of my way, I would call on him; and that we should send her some medicine, and visit her again together, very soon. She requested that the *medicine might not be in the form of a liquid, as she could not take it if it were.*

I found that the family medical attendant had been applied to, in consequence of a pain affecting the right side of her chest, in the neighbourhood of the mamma, which extended to the shoulder, and, subsequently, down the arm, which had seized her in a moment while weighing something in the shop. That for this, he had recommended a few leeches, some pulv. ipec. comp., with calomel. For a purgative saline mixture in the morning, which was constantly vomited, pills, composed of compound extract of colocynth with a little croton oil, were substituted. The following day, she having complained of a peculiar sense of pain behind the sternum, a blister had been applied there; and she had, likewise, a few doses of calomel and opium in the form of pills, as well as some compound spirits of lavender to drop on sugar, and take on account of flatulence, with which she thought she was much annoyed. I suggested the beginning immediately to give her, every hour, four grains of extract of hyoscyamus, with four grains of camphor, formed, by means of two or three drops of alcohol, into three pills; and that we should visit her in three or four hours, which was agreed to.

Hora; 11, A. M.—Says she feels rather better. Pulse irregular and intermittent. Respiration as before. Cannot bear any thing to approach her suddenly, "because it takes her breath." This symptom, it appeared, was observed first on the evening of the day before yesterday. A door leading to an adjoining apartment was noticed to have something hung carefully upon it, and on enquiring the reason for it, she said—the air that came from it "seemed to suffocate." I now left the bedside, and subsequently the room, for the purpose of ascertaining from her husband, whom I had not seen at the former visit, whether she

had not received some injury from a dog or cat. He replied, that she *had* been bitten by a young dog; but that it happened between three and four months ago. The nature of the case being now perfectly clear, the usually fatal tendency was pointed out to him, respecting which, however, he seemed, immediately from the inquiries, to be in a painful manner impressed. We deemed it prudent to suggest, that, if agreeable to him, the opinion of another physician be taken, in consultation. This he altogether declined, considering it, as he said, quite unnecessary.

When we returned to the bed-room, she was asked to take a drink; after hesitating, she at length consented to try, requesting she "might not be looked at." She took hold of the glass—which, according to her previous desire, contained but little fluid—in a snatching manner, and, having held it for some time in her hand, looking around her with much expression of suspicion, suddenly threw the liquid into her mouth, and, with a very peculiar convulsive effort, got into the oesophagus the greater part of it. For a few seconds afterwards, she was in a state of considerable agitation. Some slight incoherency, it was said, was yesterday observed; and though no allusion had ever been made in her hearing regarding the nature of the affliction with which she was assailed, she appeared to be despondent as to her recovery, unless some change speedily took place in her sensations. The bowels have just now acted. Evacuations of healthy appearance. Three doses of pills have been taken.

Contin. Pil. quæque horâ.

Applice quam primum Emplast. Cantharid.

Nuchæ posteriori; partè Nuchæ primæ optime affrictu cum Liq. Ammoniacæ curaturque postea pars excoriata. Unguento infra præscript.

Rt. Morph. muriatis, gr. iv.,

Unguenti hydrarg. fort. 3j. M.

Hora 3, P.M.—She is now sitting up by the bed-side. Action of the heart very irregular, and pulse intermittent. Respiration, however, more free from sudden sighing. Apprehension of fluids nearly the same; and refuses to attempt to swallow if observed by any one, though she is thirsty, and the tongue is coated and rather dry. Complains much of narrowing, or closing up, of the throat. Blistering

of the neck not yet managed, the ammonia having been but imperfectly applied. It is now renewed, and has been done freely. She takes her pills pretty well, and expects they are to do her good.—Contin. pil.

Hora 7½, P.M.—Appears more tranquil. Dread of liquids, and of swallowing them, less than formerly. Says she went of her own accord this afternoon to the washing stand, and washed both hands and face in the basin. A short time previous to this visit, a messenger came to my house, to say that the blister had not risen, and that she appeared not so well. The following was in consequence directed to be rubbed on the part:—

Rt. Ung. hydrarg. fort.

Emplast. cantharid., ana 3ss.

Morph. muriatis, gr. v. M.

The part is now vesicated, a portion of it being quite denuded of the cuticle. To be now dressed, therefore, with the muriate of morphia and mercurial ointment, formerly ordered.

To continue the pills every two hours only, a third part of a grain of the powder of digitalis being added to each dose, and a tablespoonful to be taken every fourth hour of the following mixture:—

Rt. Liq. ammoniacæ acetat. ʒij.

Antimon. tartariz. gr. ij.

Mist. camphoræ, gr. v. M.

Hora 10½, P.M.—She is more tranquil, and still less timid about attempting to swallow liquids, though she takes very little, and dwells over it before she makes the attempt, accomplishing it after all with a similar struggle. Pulse, &c., the same.

Contin. pil. et mist. rept. ung. morphiæ.

Aprilis 2.—A messenger came to me early in the morning, to say that she had had a tranquil night, and was better.

Hora 10, A. M.—A good night, having slept about five hours composedly, and when she awoke, she took toast and water more unreluctantly. She has also eaten some cake and a little toast, and drank about a breakfast-cupful and a half of coffee. Speaks quietly and rationally. Says she feels a great deal better—indeed appears so. Pulse, on my first entering the room, about 120, not very steady. Soon afterwards it seemed to fall to 72; and examining the action of the heart by the ear, it was found to consist of a sort of

double contraction of its cavities, or of an incomplete and complete contraction, with the latter of which the number last mentioned of the pulse synchronised. She says the sense of narrowing or filling up of the throat is diminished, and that she does not dread the use of liquids so much as she did. She can also now allow a person to approach her without sobbing or shuddering as formerly.

Contin. Pil. Mistur. et Ung. Hydrarg. cum Morphise muriat.

Hora 3, P.M.—About an hour after last visit, the sense of stricture in the throat, with increased dread of swallowing, returned with renewed severity. She is again in much agitation, and all the symptoms already described are much aggravated. She falls suddenly into an apparent state of coma, while propped up in bed—the eyes being turned completely upwards under the eye-lids—the breathing becoming stertorous, and in a few seconds she suddenly starts up, as if in a state of alarm, and talks, or mutters, something incoherently—dropping very soon into the same state. She then *picks at the tip of her tongue, as if to bring something from thence.* When spoken to, she answers abruptly—appears alarmed, and if asked to put out her tongue, she stares vacantly for a little, and then, as if with a convulsive effort, protrudes it with some violence. The face sometimes is suddenly suffused, and then as suddenly becomes pale. There is much restlessness, and she requires frequently to be raised up to the sitting posture. There is much expression of suspicion again exhibited in the countenance; there is shuddering from the approach of any one; nor can she bear the light from the window to fall upon her face; and her arm, when taken hold off, is felt to be affected at times with a sort of twitching, analogous, in some degree, to that which occurs in chorea. She takes the pills and mixture; and, at her own request, has had six leeches applied to her throat, which bled freely, by which she thinks she was a little relieved. No stool.

Eight leeches to be repeated;

Contin. Pil. et Mistura;

Exhibeatur enema domesticum.

Hora 11, P.M.—Bad symptoms all appear to be considerably augmented. She is now frequently incoherent; at times irritable; and she has increased struggle and agitation in

attempting to swallow. Glyster brought away very little. Pulse 146—irregular—small, and more compressible.

Rep. Enema. Contin. Pil. Mistur. et Unguentum Nuchæ.

To have the vapour bath at as high a temperature, and to remain in it as long, as she can bear it.

Aprilis 3, Hora 10 A.M.—The vapour bath not being procured, a warm fluid one was substituted; which, however, it appeared she much resisted, and in the struggle *bite her sister's finger.* There is at present an almost incessant action with the lips, tongue, and throat, accompanied with the emission of a sound which, in some degree, reminds one of the *barking of a dog*; this, the attendants say, "was very violent in the night." Her mouth contains a good deal of a frothy mucus, which she keeps endeavouring to part with, and at times to pull out with her fingers. She had talked during the night of dogs. Much delirium, restlessness, and agitation, and her condition is altogether most deplorable. Pulse rapid, irregular, and much more feeble; skin more warm; attempts to swallow are now distressing—almost beyond the power of description. Glyster operated very well.

Intermitte pil. Contin. mistur.

R. hydrarg. cum creta ℞j.

Pulv. ipecac. gr. i.

Sacchari albi 3ss. M. et in chart. sex divide, quarum capt. i. tertia quæque horâ. The vapour bath again recommended to be used, if it could be accomplished.

Hora 4, P. M.—Symptoms now rapidly progressing, though the attendants say she has been more tranquil since taking the powders. Pulse very frequent, thready—at times imperceptible; respiration hurried, irregular; pupils small and contracted; eyes more glassy; constant delirium; much froth coming from the mouth. From this period she gradually sank; and at half-past eight expired, it was stated, "in a kind of convulsion."

Having made further inquiry into the circumstances attending the bite of the dog, I learned that about a month before Christmas last, a little pup, two months old, which appeared to be not quite in its usual state of health from teething, and had, in consequence,

got some medicine, snapped frequently at Mrs. S.'s hands while nursing it, and bit the thumb and three fingers, as well as one of her legs, near the ankle. That the dog died the following day. That, in two days more, small blisters formed on the injured parts of her hand, which required poulticing, and were very painful and troublesome for about a week longer. After this time, she was in her ordinary health, and for a few weeks previous to the occurrence of the fatal malady had been better than usual. I learned, likewise, that her daughter, an only child, and two other persons, had their hands snatched at by the same dog on the same day; but neither was the skin in them broken, nor did any vesications follow. It only remains for me, in conclusion, to add, that an autopsy, after having been consented to, was subsequently withheld, and thus was prohibited an opportunity of perhaps adding another to the proofs on record, of the obscurity in which is still involved, the pathology, as well as the practice, in this most appalling disease. It were perhaps unnecessary, therefore, to have given to the world a detail of this case, were it not for the very great and most decided amendment which took place in all the symptoms, during from twelve to twenty hours—an amendment so marked, indeed, as to encourage some temporary hope of ultimate recovery; and which consequently might perhaps throw a ray of light, however faint, upon the at present obscure path in which all have to tread, to whose unhappy lot it falls to have the management of so intractable a malady.—*Liverpool Medical Journal.*

Foreign Medicine.

ACADEMIE DE MEDECINE.

Sitting, April 1st, 1834.

President—M. LISFRANC.

New Researches on permanent Retraction of the Fingers.

BY M. GOYRAND, SURGEON TO THE HOSPITAL OF AIX.

M. SANSON opened the discussion by exposing the history of science on permanent retraction of the fingers. We have nothing to do here with that which might be owing to cicatrices,

to ankylosis, or to paralysis of the extensors, but only with that affection which, before M. Dupuytren, was attributed to the contraction of tendons (*crispatura tendinum*), and that M. Dupuytren has since referred to retraction of the palmar fascia. The dissections made by M. Dupuytren, and the first operations by which he was successful, gave at first complete support to this theory; but, subsequently, a patient, in whom he had divided transversely the bridles of the palmar fascia, required, for a complete recovery, that other bridles should be divided along the anterior surface of the retracted fingers. In this fact there was something which escaped the theory of M. Dupuytren, and it is this new and unknown cause that M. Goyrand has attempted to investigate.

A man, 72 years of age, who had a very old contraction of the fingers, died in the Hospital of Aix. On dissection it was found that this retraction was owing to fibrous bands of a new formation passing from the palmar fascia to the sheaths of the tendons, from thence spreading over the lateral parts of the phalanges, and even from one phalanx to the other.

M. Goyrand draws two conclusions from this fact; first, that retraction of the fingers is always produced by these bridles; secondly, that the latter are of new formation.

As to the first conclusion, the commission has thought it carried too far; M. Dupuytren's observations tend to disprove it. With regard to the second, it has been suspected, *a priori*, that these accidental bridles might very well be mere enlargements of bands existing in the normal state; and attentive dissections have proved the preciseness of this opinion.

[M. Sanson here exhibits to the Academy several beautiful dissections of hands in the normal state. Independent of the deep prolongations of the palmar fascia, several superficial ones may be noticed, which are sent off from it to the integuments of the hand, and to the sheaths of the tendons, even as far as the extremities of the fingers.]

M. Goyrand's memoir is not purely anatomical. It is well known that M. Dupuytren divides, transversely, first the skin, then the subjacent bands. M. Goyrand thinks that the transverse section of the skin becoming much wider when the fingers are

straightened, presents too extensive a surface for cicatrisation, thereby retarding a cure. He therefore proposes to make a longitudinal incision into the integuments, and a transverse section of the bands only.

Another fact, mentioned by him, adds something to the history of these retractions. It was generally believed that they affected the middle, ring, and little finger at most. M. Goyrand has seen a case where the thumb was in like manner attacked. Again, they were attributed to excessive manual labour. The person who was the subject of this report has for the last twenty years acted as writer in the administration of the Hospital of Aix.

The commission proposes to send the memoir to the committee of publication, and to inscribe the author's name on the list of candidates for the rank of corresponding member.

M. H. Cloquet mentions having observed a case of retraction of the fingers, the cause of which manifestly resided in the flexor muscles; the tendons, when the fingers were attempted to be straightened, became so prominent under the skin, that they might have been supposed to be luxated from their sheaths. It were therefore wrong to attribute these accidents always to the palmar fascia and its bands.

M. Barthélemy.—We often find a similar affection in horses, which seems to be confined to the fore limbs; this is a flexion of the foot, which is owing to a retraction of the flexor profundus or perforans.

Veterinary surgeons are in the habit of dividing the tendon opposite to the metacarpal bone,—immediately the foot is straightened; the two ends of the tendon unite at the proper distance, and the limb resumes its direction and all its former solidity. Several examples of it have been mentioned in the *Journal de Médecine Vétérinaire*. Some of the horses, thus operated on, work in the neighbourhood of the school: one of them is now at Charenton, in the employ of the administration of public coaches.

M. Sanson.—Veterinary surgeons are, then, more fortunate than we; for I have seen, in similar cases, section, and even excision, of the tendons, and doubtless others have witnessed the same operations, without any relief to the retraction of the fingers.

M. Dussuy states that he performed the

operation named by M. Barthélemy on a horse, and that the shortening returned.

M. Velpeau.—We must carefully distinguish causes, in order to appreciate rightly their results. Formerly, the disease was attributed to the retraction of tendons. M. Dupuytren has proved that this is a very uncommon case, but we should not on that account deny it; for, besides that M. Barthélemy has proved it in the horse, cases of it have been manifestly discovered in man. I would mention, as an example, the tendo-Achillis, the retraction of which M. Delpech has treated by section, but the permanent flexion of the fingers is more particularly produced by fibrous bands, and I completely agree with M. Goyrand on the subject. Last year I had under my care at La Pitié three patients with retraction of the fingers; two of them were so aged that I would not attempt the operation, but the third, a young man, 28 years of age, readily submitted to it; I made an incision into the integuments, then cut the fibrous band, and even dissected it out completely; underneath this band I could easily recognise, at the bottom of the wound, the palmar fascia remaining entire. I published this case with all its details at the time.

M. Sanson answers that the band, cut out by M. Velpeau, was a cutaneous prolongation of the fascia.

M. Martin Solon—what are called retractions of tendons are, properly speaking, merely muscular contractions: thus, I have under my care at Beaujon a woman, whose foot is extended on the leg by the action of the gastrocnemii muscles. When flexion of the foot is attempted these muscles, by their resistance, acquire an excessive hardness. I have used belladonna by friction, and this plan already has sensibly diminished the retraction.

The report of M. Goyrand, with his conclusions, were then put to the vote and adopted.

MM. Villermé and Gueneau de Mussy propose to send also the Report to the Commission for publication, as it contains historical details which are wanting in the Memoir. M. Lisfranc requests, if this motion be adopted, to add to the Report some mention of Sir Astley Cooper's researches on the subject, the which were even anterior to those of Dupuytren.

Both these propositions were adopted.

Re-appearance of Cholera in Paris.

We regret to state that the cholera has again made its appearance in Paris. The cases, as yet, have not been very numerous, but some of them have proved very severe.

The number of deaths from this disease during the four months of April, May, June, and July, in the year 1832, is worthy of notice.—It would appear from the results of official inquiries, that the total number of deaths from the cholera, in Paris, within the above four months, amounted to a forty-sixth part of the whole population. In furnished lodgings alone, 2342 were attacked, of whom 1033 fell victims to the disease; and by comparing the number of fatal cases, occurring in those quarters of the metropolis principally inhabited by individuals of easy circumstances, with those having taken place in the more dirty districts, it is found that the mortality exactly corresponds to the greater or less degree of insalubrity of the habitations. In some small streets, as many as thirty-one deaths have been known out of forty-one cases; and in many lodging-houses, from four to twelve have perished in a house. The mortality was principally observed among those wretches who indulge in debauchery, and all other kinds of vices.

The poisonous Effects of the Cyanuret of Potassium by Injection.

A man attacked with neuralgia of the trunk, after having had three injections, each composed of six grains of the cyanuret of potassium, in six ounces of water, the cyanuret being in a state of deliquescence, two of them administered cold, and the third warm, suffered from severe convulsions, and violent contractions of the limbs; his eyes, for some time, became fixed, and the pupils were dilated. After the effects went off he found himself much better, and was able to get out of bed, which for a twelvemonth he had been unable to effect. A fourth injection was administered, which contained the same quantity of the cyanuret of potassium, but this was more moist than the former, and from it he experienced neither pain nor unpleasant symptoms; receiving no benefit, thirty-six hours afterwards a fifth was administered, in which was the same dose of the cyanuret, but very dry, and taken from a bottle, which had not till then been uncorked, and exhaling but little odour.

In the course of an hour afterwards he suffered from general convulsions, palpitations of the heart, slowness and difficulty of respiration, coldness of the limbs, dilatation of the pupils with the eyes fixed: he died.

This fact establishes a marked difference in the action between the cyanuret of potassium when dry and in a state of humidity, which is probably owing to a decomposition taking place in it when exposed to moisture. This opinion is held both by M. Orfila and M. Pelouge.

Hydrophobia cured by Bleeding and exhibition of strong Vinegar.

A case of this terrific disease is related in a Bourdeaux journal by M. Dubedat, jun., to have occurred in a woman residing at the Commune de Villeton, near Tonneins, aged 32, of a bilio-sanguineous temperament, robust, and the mother of three children.

On the 23rd of April, the father of the narrator was sent for, as well as several other practitioners in the town, the friends believing her to be attacked with hydrophobia. On their arrival, the woman being in a state of calmness, stated to them, that on the 18th of March, when returning from work with her husband, a dog bit her in the left heel; the animal was said to be in a rabid state, had bitten several of its own species, and had since been killed; also all the animals that were bitten by it were ordered by the mayor to be served the same fate. On hearing this account of the animal she became much alarmed; the wound by this time had nearly cicatrised, and she endeavoured to soothe her mind by forgetting it. For the last eight days she has been in a constant state of excitement, made use of several curious expressions, so that her friends imagined her to have taken an unusual quantity of strong beverage; this irritation has increased every day, feels thirsty, but on seeing or touching water is much excited. The cicatrised part now became swollen, red, and itching. Every day the paroxysms increased, and at present she is unconscious when they make their approach, and has a strong inclination to bite. She had no sooner made this narration, which was confirmed by her husband, as well as several others, than a severe fit came on, general convulsion supervened, her eyes became glassy and wild, vio-

lent constriction of the larynx, suffocations; foaming at the mouth, delirium, screaming and howling, and was obliged to be tied down; pulse small and soft. The attack lasted four minutes. The practitioners, not having any doubt as to the nature of the disease, determined to employ copious bleedings and baths; the use of the strongest vinegar was also proposed during the accessions. Two pints of blood were drawn from the arm, when a state of perfect calm ensued. Some *tisane* (infusion of herbs) was offered to her, and had no sooner touched her lips than she fell back, and was seized with violent convulsions. A glass of the strongest vinegar which could be procured was then forcibly administered, and about three ounces of which was calculated to have been swallowed. The convulsion instantly ceased, twenty ounces of blood were again taken, and the attack did not return for two hours. As soon as the symptoms reappeared, another dose of vinegar was given, which proved as effectual as the first. The success of this treatment induced the practitioners to persevere strictly in the same course. The next day there was only one effort toward convulsion; after this she was able to drink, and no other symptoms returned; and in a week she resumed her daily occupations.

Clinical Remarks on Gun-shot Wounds.

BY M. SANSON.

All bodies propelled by means of fire-arms have two distinct powers of motion, one of impulsion, the other of rotation; the latter, which is common to them, with all other projectiles, is one of the most powerful causes of that deviation which is given to their course, when, after penetrating soft structures, they reach a bone that will not yield. The contusion attending gun-shot wounds presents three degrees of severity, in cases in which wounds have been produced, as well as in those in which no lesions of integuments can be found. 1st. The contusion may be slight, in which case resolution takes place readily, and the cure is rapid. 2nd. If it is more severe, the textures are injured, and, although its effects may not be at first evident, they become so as soon as inflammation is set up. 3rd. The injury to the tissues may be extensive, and evi-

dent at the time of the accident; and when inflammation supervenes, large eschars are formed, and the wound thus considerably increases. When the wound or contusion is accompanied with sanguineous effusions, a kind of fluctuation may be observed in the progress of these collections, which at one time increases, at others diminishes. A tumefaction often decreases by the rapid absorption of the serous particles of blood; a hard clot is thus formed, which can only be dissolved by a free afflux of the more fluid parts. In some cases the tumefaction remains, although none of these clots be present: this is owing to the death of the surrounding parts, which can no longer absorb the effused fluid.

Wounds complicated with contusion generally present the same phenomena as those of ordinary contusions; but, in those parts in which the skin covers a bony surface, their section may be as neat as that caused by a cutting instrument, and we may then obtain union by first intention.

If a contused wound is small, we have not unfrequently abundant sanguineous effusions, attended with phlebitis, erysipelas, or gangrenous inflammation. The presence of air in the cavities may give rise to these accidents, we should therefore attempt, if possible, to obtain resolution before we enlarge the wound.

Bullets or other projectiles act, then, in two different ways,—1st, by simple contusion; 2ndly, by their own peculiar rotatory motion. Cannon balls and spent bullets generally produce simple bruises; if they cause wounds it is by their rotatory motion, which destroys the parts.

Gun-shot wounds are black and dry; the eschars are owing to the attrition of the parts, and not to the heat of the ball; for if the elevation of temperature were such as to cause a burn, it would have produced fusion of the missile. The shape of the wound varies according to the figure and volume of the projectile, and of the part affected. It is always found, however, that when a ball passes through any part of the body, the wound through which it entered is shrivelled, depressed, and smaller than that through which it escapes, which is torn and pointing.

It is said that these wounds do not bleed;

this is true only when the parts traversed contain no vessels of great size: they certainly bleed less than wounds of the same parts made by cutting instruments. But if a large artery should be lacerated, fatal hæmorrhage is the immediate result. Sometimes a swollen state of the tissues, the formation of a slough, the presence of foreign bodies, may arrest the hæmorrhage. It may happen that the parts injured by the bullet should displace a large artery, which otherwise would have been wounded.

One symptom of gun-shot wounds is the stupor, either local or general, which is produced, but this is far from being constant. The surprise or fear of the person wounded produces this phenomenon rather than the pain which in most cases does not immediately supervene. By local stupor is meant that state of a limb in which it remains cold, livid, and motionless. General stupor is accompanied with disturbance of the intellectual and sensitive functions, or with syncope, with smallness and concentration of the pulse, coldness, discoloration, and lividity of the skin, insensibility, loss of motion.

Projectiles, when propelled with force, seldom produce any commotions; as, after a wound produced by them in this state, many persons have been known totally unconscious for some time after the reception of the injury. We have, in the *Salle St. Jeanne*, patients who have illustrated this remark. A cannon-ball may even carry off a leg, and the sufferer will experience the want of support only.

If, however, the motion of the projectile is less rapid, if the bones are comminuted, and the soft parts lacerated, the stupor, both local and general, supervene promptly. A cannon-ball may, when nearly spent, carry off a man, and project him twenty or thirty yards distant, in which case, there are cerebral commotion and general stupor.

Lastly, much loss of blood, cold, dampness, want of assistance, or fright, may bring on general stupor, without any cerebral commotion.

Balls and bullets often take a devious course. M. Sanson mentions two individuals who had received pistol balls, the muzzle of the pistol having been applied to the chest; the cavity of the thorax had not been penetrated, but the bullet had followed the external

surface of the rib under the integuments, and had come out at a point exactly opposite that of its entrance. M. Larrey quotes the case of a soldier, who was wounded by a bullet in the centre of the forehead, near the longitudinal sinus, the course of which it followed to the occipital suture, producing the symptoms of compression. An elastic probe was introduced, and when the exact situation of the body was ascertained, it was removed by means of the trephine, and the patient soon recovered.

THE

London Medical & Surgical Journal

Saturday, May 17, 1834.

SALUBRITY OF LONDON.—POPULATION.

ALL writers on statistics, both in this country and abroad, admit that London is the most healthy capital in the world, as estimated by the average mortality of its population. It is impossible to observe its relative cleanliness and airiness, the domestic habits of the great bulk of its inhabitants, and their wholesome food, without feeling convinced that there are fewer causes of premature decay in operation within its limits than are to be found concentrated in most of the capitals of Europe. The comparative estimate of the number of deaths to the amount of population leads to the same result; and the advantage in favour of London, upon this calculation, seems too great to be materially reduced by any admissible error in the population returns. At the same time it is very true, that the Bills of Mortality are made up in a most unsatisfactory manner, as far as the Worshipful Company of Parish Clerks are concerned; and the principles upon which their correction is attempted are very arbitrary. In this regard the calculator, like a celebrated clerk of Mr. Pitt's, may prove any foregone conclusion he pleases.

: Were, however, the numbers ascertained with the last exactness, we should still doubt the propriety of admitting them as legitimate evidence in the question of the relative salubrity of different cities. In London the constant influx of strangers is greater than in any other capital in the world. A large portion of its population, at any given day, will have departed, and made room for fresh arrivals, in the course of six months.—Add to these circumstances the facts, that of its inhabitants, but a small portion are born, and still fewer are nursed, in the metropolis, and that great numbers, as age or sickness approach, retire into the country in pursuit of health.—When we consider how materially these fluctuating causes affect the result, and that it is almost impossible to calculate the full extent of their influence, we are disposed to rest our conclusion in favour of the salubrity of London rather upon the superior economy of its inhabitants than upon numerical deductions.

Some of the pamphlets, published on behalf of the College of Physicians, have adverted to the inferior mortality of London, as evidence of the capacity and qualifications of its medical practitioners, and the idea has been seized upon by others with strange avidity. For our parts, as an argument in support of the present system of medical institutions, we consider it utterly unworthy of serious notice, and respect for truth will not allow us to be parties to a pious fraud in honour of the profession. The scavenger, the butcher, the baker, and the brewer have juster claims than all the fraternity of Galen, as the great supporters of human health;—and until we can ascertain the relative number of sick in London and Paris, the causes and nature of their diseases, and the cures of each kind, it were pre-

mature, as, we have no doubt, it would upon proper information turn out to be false, to infer that the practitioners of London were superior in medical skill to the faculty in Paris.

We cannot dismiss this subject without noticing Mr. Brougham's Bill for establishing a general register of births, deaths, and marriages. Much as we may appreciate its immense importance in a legal point of view, professional motives also call forth our admiration of this practicable piece of legislation. If carried into effect, as we sincerely hope it may be, it will supply the amplest information on every thing relating to the population of the kingdom. Under its operation for a few years we shall have data to solve some of the most interesting questions affecting a nation, with an accuracy hitherto unattainable on a large scale;—whilst, at the same time, we may isolate any particular district, and trace its deviations from the average.

The learned member entered into some curious calculations, in order to ascertain the expense of his proposed plan. He estimated births at three per cent on the whole population, deaths at two per cent, and marriages at one in one hundred and twenty-eight, whence he calculated the average number of registrations in the year at 810,000. There are about 16,000 parishes in England and Wales, in each of which there is a collector of taxes, an intelligent officer who is in constant communication with London. To this officer Mr. Brougham proposes to entrust the registration of births and deaths, at a small fee, sufficient to quicken him in the discharge of his duty, without burdening the country beyond the value of the object to be attained. By allowing him 5s. each upon the first ten entries in his book, and 2s. 6d. each for the next ten,

and 1s. each for every succeeding entry, the expense is estimated at 69,587l.; and this fund it is proposed to raise by a rate on each parish.

We observe the Treasury has assented to the practicability of the scheme of which we have given the outline. As far as we can form a judgment upon its feasibility, we shall rejoice at its adoption, as it seems to us well calculated to accomplish the great national object it has in view.

EDUCATION IN PRUSSIA.

THE organisation of the medical profession in Germany, and particularly in Prussia, has very frequently been alluded to by the periodical press.

In Prussia, our readers are well aware, that medicine, as one of the great branches of science, is under the especial control of a minister of the crown, assisted by a medical council. We much regret that the second part of M. Cousin's report to the French Minister of Education, upon German public instruction, is not yet published, as we have longed to condense, after so able an observer, an account of medical education and police in that country. In the meantime, we have now before us an admirable translation of that part which relates to the public provision for popular education in Prussia, from the able pen of Mrs. Austin*.

"Constituted as the government of this country is," observes Mrs. Austin in an excellent preface, "and accustomed as it is to receive its impulses from without (a state of things approved and consecrated by the national ways of thinking), it would be contrary to reason and expe-

rience to expect it to originate any great changes. This is not recognized, either by government or governed, as any part of its duty. It is to the public mind, therefore, that those who desire any change must address themselves."

This just observation is confirmed by the history of the origin and progress of every institution in the kingdom; and in nothing is its truth better illustrated than in the affairs of medicine.

There is such a thing, however, as a tyranny of system and of good intentions; and experience has shown the possibility of providing for the cultivation of the arts and sciences in the highest degree, under the direct patronage of government, and even of drilling a nation through certain forms of education, in the manner and measure of military exercises, where not a spark of genuine liberty is to be found. To what extent it is advisable, or the public mind in this country is prepared, to call for the interference of the legislature in the cause of national education, this is not the place to discuss. But we strongly recommend to the attentive consideration of every person awake to these important interests the perusal of Mrs. Austin's very valuable translation. And we earnestly hope she may be encouraged to favour us with a like account of the Universities of Prussia, and especially of the construction of its Medical Schools, in the control of which the policy of a direct interference of the state is not to be questioned.

LONDON UNIVERSITY.

AFTER having lately expressed our opinion, more in sorrow than in anger, upon the injudicious determination of the senate in urging its claims in regard to medicine, we shall merely add an ex-

* Report on the State of Public Instruction in Prussia. Translated by Sarah Austin. London: Wilson. 1834.

tract from a recent law lecture*, delivered by Professor Amos, from which it appears the conduct of the senate has been far from satisfactory in other respects.

"The Professor adverted to the recent discussion before the Privy Council, respecting the charter of the London University. He observed that the proceeding on the part of the petitioners exhibited a mixed character of ignorance and impudence; and he begged to enter his protest against being supposed to have had anything to do with the argument on constitutional points, and against any impression that the case of the University had received anything but gross injustice from the hands of its very *injudicious* and very *ill-informed* friends."

HEALTH OF THE METROPOLIS.

During the last few days diarrhoea has been unusually prevalent, and there is reason to apprehend, from the early appearance of this disease, that cholera may again visit us. Bowel complaints are common at the end of summer, or beginning of autumn, but are very rare in May. The disease now prevalent is preceded by indigestion, languor, and lassitude, sinking at the pit of the stomach, and great debility; in fact, the symptoms which preceded cholera in 1832 and 1833. Ordinary remedies arrest it, and the timely application is indispensable. Regularity of living, nutritious diet, and moderate mental and corporeal exertion are the best preventives. Vegetable food, more especially salads, lettuce, &c. ought to be used sparingly, if at all.

GREAT WESTERN CEMETERY, Notting Hill, Kensington Gardens.

This national work is now completed. The site comprises 52 acres, with woody plantations, gravel-walks, shrubs, gardens, bordered by an extensive range of trees. There could not be a fitter spot for a burial place, and this

cemetery will, at no distant day, bear a close resemblance to that of Père la Chaise, near Paris. We wish it every success, and congratulate the public on the benefit the health of the metropolis will derive from a removal of the dead from its crowded churchyards.

Reports of Societies.

MEDICO-BOTANICAL SOCIETY OF LONDON.

Tuesday, May 13th, 1834.

HUMPHREY GIBBS, Esq. in the Chair.

Contagion a Nonentity.—New Nosology.

Dr. TYTLER gave a most learned account of the ancient opinions on contagion, in which he adduced various proofs, both from the sacred and profane writers, in support of the opinion which prevailed in the early ages and at present in India, that an evil spirit, a pneumonia, an air, was the cause of pestilential diseases. He selected many illustrations from the histories of India, Egypt, Asia, &c. in support of this doctrine. He denied that Hippocrates, Celsus, Galen, Avicenna, Rhazes, &c. had ever mentioned the word contagion, and believes it was introduced by the clergy at the Council of Trent, or some other council, for the purpose of deterring the emperor from entering the town. He quoted various texts of scripture to prove that grain was deteriorated previous to the appearance of pestilence, and mentioned numerous historical facts in support of the opinion that famine preceded pestilence. He cited the work of Dr. Mead, to show the identity between the morbid appearances in plague and Asiatic cholera. He denounced the doctrine of contagion as the bane of medicine, and forcibly delineated the horrors of quarantine on society. He ridiculed the opinion that Asiatic cholera was contagious, and stated that he was the first British medical officer, who had seen the disease in 1817, and traced it to the use of deteriorated rice. He felt as convinced as he was of his own existence, that Asiatic cholera was not contagious, or communicable from one individual to another, but that it was caused by deteriorated rice, which was consumed in every country where the disease had appeared. He quoted Mr. Goodman, a Jewish writer, who holds

* The Legal Examiner, May 14, No. 62.

that vegetable life is derived from the earth, and animal life from vegetable. He argued that deteriorated grain and other vegetable food were the causes of plague, yellow fever, cholera, typhus, &c. He quoted various medical and historical works in support of this opinion. He laid his nosology on the table, which he founded on this basis; and emphatically and eloquently portrayed the baneful influence of contagion and its infernal consequence, quarantine, on both humanity and medical science. He thought the subject of his nosology a legitimate one for the consideration of the Medico-Botanical Society, and trusted that it would be carefully and candidly examined. (*Loud cheers.*)

Dr. Sigmond complimented the learned Doctor on his great research and ability; but, though a non-contagionist, he could not assent to many of his conclusions. He fully agreed with Dr. Tytler, that cholera was not contagious; but he was of opinion, that many of the diseases, mentioned in his nosology, might arise from various causes besides deteriorated grain. He thought that small-pox, itch, and other diseases were decidedly contagious. He then gave an excellent account of the plagues, mentioned by classic and medical authors, and agreed with Dr. Tytler, that there was not sufficient evidence to warrant the conclusions, that many of them were communicable by contact.

Mr. Judd also passed a high encomium on Dr. Tytler, and thought most of his views well worthy of serious consideration. He could not, however, assent to the statement, that no allusion was made in the Mosaic law to contagious diseases, and referred to Leviticus in support of his opinion.

Dr. Tytler replied to both the last speakers, but the time of the Society having elapsed,

It was moved by Mr. Judd and seconded by Dr. Ryan, that the subject be resumed at the next meeting on the 27th instant.

We owe it to the Society and Dr. Tytler to state, that we have only given an outline of the discussion, but shall do it ample justice after the next meeting. We fully agree with Dr. Tytler as to the absurdity of the modern doctrine of contagion, and stood alone, as to the non-contagiousness of cholera, against the Central Board of Health, when there was not a physician in Great Britain of our opinion,

except Dr. Sanders*, of Edinburgh. We saw the day, however, when the profession in France, almost unanimously, and there was only one solitary exception, confirmed our views; and the result was, that, on the re-appearance of the disease in 1833, we had no Cholera Boards, notwithstanding the absurd Cholera Act, no quarantine, no alarm, to fright the isle and world from its propriety. We owe it to the fourth constitutional state,—the public press,—to acknowledge, that its promulgation of our views put an extinguisher on cholera contagion and central Boards of Health.

Reviews.

The Dublin Journal of Medical and Chemical Science, including the latest discoveries in Medicine, Surgery, Chemistry, and the Collateral Sciences. No. XIV., Vol. V. May. . Hodges and Smith.

THE original communications in this number of our esteemed contemporary are extremely practical and valuable. They are evidently the productions of experienced practitioners. We shall notice the most important of them at present.

The first article is on the Use of Mercury in Ulceration of the Cartilages of the Joints, by Dr. O'Beirne. He commences his paper by alluding to the extreme suffering and destructive alterations in diseases of the joints, which have often defied all remedies, and led to the loss of limb or life. He cites the opinion of Mr. Brodie as to the incurability of ulceration of the joints, and then proceeds as follows:—

“Mercury, from its decided and happy effects in all kinds of membranous inflammation, always appeared to me to be the only agent capable of answering the various ends in view. But the injurious consequences so generally said to attend its use in scrofulous persons, who are so frequently the subjects of this affections of joints, deterred me for a long time from giving it a trial. The following considerations, however, could scarcely fail to have great weight. In the first place, it must be admitted, that injurious consequence have

* See London Medical and Surgical Journal, vol. iii.

not always attended the use of mercury in strumous persons, and as far as my experience has led me to observe, they have supervened chiefly in cases where ptyalism has been produced slowly, or only in a slight degree. Secondly, we are not without means of anticipating and preventing the supervention of such consequences, or of combating them when they have supervened. Thirdly, in cases of syphilitic iritis occurring in acrofulous persons, we do not hesitate to use mercury, so as to produce ptyalism as rapidly as possible, in order to save the eye; and yet, we rarely observe serious consequences to attend the practice. Fourthly, it is manifest that there is much greater danger in permitting such a disorganising process to go on unchecked in the cartilages of joints, than from any of the ordinary consequences of the free use of mercury in strumous habits. Ultimately, these considerations prevailed, and decided me on giving this agent a trial in cases of the description under consideration; and to employ it so as to act rapidly and fully on the mouth. The first trial was made, about a year ago, in the case of a woman admitted into the Richmond Surgical Hospital, with ulceration of the cartilages of the knee-joint. In this case, the value of the mercurial plan of treatment seemed to be established by the disappearance of all the symptoms, as soon as the mouth became affected; and by the fact of the woman regaining the full power of walking, and being discharged perfectly well, in the course of a fortnight from her admission. Since that time, I have tried the same plan in similar affections of the joints, and with similar results. Three of my colleagues in the Richmond Surgical Hospital, and Mr. Cusack Roney, one of the senior surgeons of the Meath Hospital, have also employed it with success."

Dr. O'Beirne details several cases of disease of the wrist, knee, ankle, and hip-joints, occurring in children about the age of puberty, and in adults, which rapidly yielded to the use of mercury, used to the extent of making the mouth sore. Some of these cases were seen by Dr. Peile, Mr. Carmichael, Dr. M'Dowel, Dr. Fry, Mr. Cusack Roney, and others.

This is a new and valuable practice, and reflects great credit on the originality and sound reasoning of Dr. O'Beirne. If mer-

cury be found a remedy for the intractable and often irremediable diseases of the joints, a great improvement will be accomplished. We cannot help detailing one of Dr. O'Beirne's cases, and from this our readers may form their opinions of the rest. Some fifty years since such would be considered incurable. Amputation remained for some, and long continued suffering and permanent lameness would be the consequence of others.

"CASE II.—James Flood, aged 23, admitted into the Richmond Surgical Hospital, under my care, on the 16th of September, 1833. About eighteen months ago he had a gonorrhoea and a swelled testicle, for which he was placed under the influence of mercury. He afterwards caught cold, his right knee swelled, and he was admitted into the Richmond Hospital by Dr. Peile, who succeeded in completely removing the swelling and other symptoms. Shortly after leaving the hospital his left knee became attacked with a dull pain, which slowly increased in acuteness during seven or eight months, until about four months ago, when it became excessively great, and the knee began to swell. At present, except at night when it is very severe, he has no pain when lying quietly, and in the horizontal position; but when he moves, or attempts to stand, or when the heel is struck ever so lightly, he immediately feels very acute pain in the knee joint. He complains also of an acute pain extending down the outer side of the leg, and terminating at the sole of the foot. The effusion into the joint is considerable; but there is no discoloration of the cutaneous surface. His general health is impaired.

"Frequent leeching, cupping to 18 ounces above the knee, blisters, lotions of acetate of lead, frictions three times a-day with strong mercurial ointment, anodyne draughts, and draughts of camphor mixture and wine of colchicum, were employed in succession, but without any benefit, until 28th Sept., when he was ordered to take a pill containing three grains of calomel and half a grain of opium every third hour.

"Sept. 30th.—Mouth not affected; no material change; pills repeated.

"Oct. 1st.—Considerable ptyalism. Pain and swelling greatly reduced; and he feels comparatively little pain in moving in bed, or when the heel is struck smartly. Pills

omitted. Ordered to have a draught of vinum colchici and camphor mixture at night.

"2nd.—Complains of severe griping pains in the stomach and bowels. Ordered a purgative draught, followed by an emollient enema; a blister to be applied to the epigastrium; and when his bowels have been freely moved, to take occasionally saline effervescing draughts, and beef tea *ad libitum*.

"3rd.—Slept soundly last night. Mouth still considerably affected; griping pains gone. Pain and swelling of the knee remarkably diminished, and very little inconvenience from striking the heel; no pain whatever in the outer side of the leg. Enema, saline draughts, and nourishment repeated. The knee to be covered with an emollient poultice, frequently renewed, and as warm as he can well bear it.

"In a few days this man found that he could stand upon the limb, and walk about without pain, but in doing so, said that the joint and limb felt very weak. He was, therefore, confined to bed, ordered frictions of soap liniment to the limb, and to have full diet. Under this plan his general health recruited, and the power of the limb became so completely restored, that he was discharged from the hospital on the 26th Oct., that is, on the twenty-eighth day from the commencement of the use of mercury."

(To be continued in our next.)

Foreign Hospital Reports.

HÔPITAL ST. JEAN.

Opisthotonos—Death—Autopsy—With some Physio-Pathological Observations on Inflammation of the Spinal Marrow.

BY C. F. BELLINGERI, PRINCIPAL SURGEON TO THE HÔPITAL ST. JEAN.

A girl, 13 years of age, of delicate constitution, affected with an immense wen on the side of the neck, who in other respects had been playing about in perfect health, was seized suddenly, without shivering, with pain in the left shoulder and region of the larynx, rigidity of the neck, also severe pungent pain in the region of the occiput, and difficulty of opening the mouth. Though she experienced

torture on deglutition, she got up, and was able to eat. The next morning she felt pricking pains along the dorsal vertebrae, accompanied by a sensation of twitchings of the inferior extremities, though she walked about. On the 27th the same symptoms continued; the rigidity of the neck became worse, so bad that she was obliged to go to bed. On the 28th, stiffening of the limbs commenced; they were drawn backwards; and the next morning the head and neck became similarly affected. From this time to the 31st she was bled five times, and took a cathartic composed of the pulp of cassia fistula, tamarinds, and olive oil, after which she passed a lumbricus by stool.

When she was admitted into the hospital she was bled from the feet, and thirty leeches were applied to the spine. On the 2nd, sixteen leeches more were applied behind the ears, and in the evening M. Bellingéri examined her for the first time.

At this time the head and neck were drawn backwards, the head slightly inclined to the right side, the spine curved, forming a convexity anteriorly; the legs and thighs were also drawn backwards, and were capable of being rendered flexed only by external force, which caused great pain. The movements of the superior limbs were stiff, the fore-arm being less motionless than the arm; all flexion appeared lost, and it could not be raised to the head. The attempt to flex either arm or fore-arm gave excessive pain. The pupils were constantly retracted, and thus remained, when a lighted candle was placed close to them or at a distance, neither sight nor hearing was affected, with the exception of a slight buzzing noise, of which she complained, annoying her every now and then. The alæ of the nose were drawn upwards, and remained in an arched position; the upper lip was also raised, and she was unable to approach the one to the other. The commissures of the mouth were slightly retracted, and gave her a kind of sardonic smile; in fact, all the muscles of the face were contracted; the cheeks hollowed, which gave to her a cadaverous aspect; sensation all over the body was perfect; great difficulty in moving the inferior jaw; was unable to protrude the tongue further than the alveolar arch. There was a certain degree of dysphagia, and she could only swallow spoonfuls of liquid. Pulse small and contracted,

104; abdomen tense and flat. In attempting to administer an injection per anum, much resistance was offered by the sphincter. The discharge of urine voluntary; heat little greater than natural; a slight and continued moisture of skin. She complained of constriction of the throat, for which the jugular vein was opened, the spasms disappearing for a short time, and returning with greater severity, so violent that it appeared to have produced death from asphyxia, owing to a spasmodic closing of the glottis. Immediately after death the left arm was drawn spontaneously backwards.

Autopsy.—Twelve hours after the body was cold the limbs remained in a state of stiffness, and in twenty-four hours flexibility returned.

Medulla spinalis.—On its posterior surface a simple sanguine extravasation without congestion was discovered, which occupied the external surface of the dura mater from the third to the sixth dorsal vertebra; on cutting through the dura mater, the arterial vessels of the pia mater, which lined the posterior part of the medullary substance, were congested, more or less, extending from the ninth dorsal vertebra to the inferior part of the spinal marrow, it existed throughout the whole extent of the posterior surface, but very extensive at its superior extremity and at its origin. In all these regions it is necessary to notice that the engorgement was limited by the posterior origin of the nerves on each side, and that it did not extend on the lateral surfaces of the spinal cord.

On the anterior face the cellular tissue which lined the dura mater, as well as the dura mater itself, was, throughout its whole extent, much injected, much more even than its posterior surface. This membrane being opened, the middle spinal artery was found much engorged with arterial blood, also some of its ramifications, particularly those in the lumbar region.

The spinal marrow itself was healthful.

Head.—Slight sanguine extravasation between the dura and pia mater; the superior part of the cerebrum was much injected with red blood, though limited to the arterial capillary vessels of the pia mater. That portion of the pia mater lining the cerebellum and annular protuberance was also much gorged with red blood, as also the inferior extremity of the medulla oblongata.

The brain was in a normal state.

Abdomen.—The jejunum and its mesentery were very inflamed. This intestine contained twelve large, long lumbrici, rolled up together. The following are the deductions drawn by the author from these facts:—the anterior surface of the pons Varolii is formed of fibres coming from the cerebellum; irritation of these fibres is capable of producing spasm in the direction of extension, principally of the head and neck, and it also causes trismus, spasmodic dysphagia, and constriction of the pharynx.

The posterior part of the spinal marrow presides over extension, in fact, we observe its injection produce this effect, but slightly, however, in the superior limbs, the injection being less intense in the cervical region; stronger, however, in the inferior, for another reason. Injection of the pia-mater of the cerebellum also demonstrates that this organ governs the movements of extension.

The injection in this case was limited to the pia-mater, and the symptoms were confined to muscular contractions. This proves, then, that irritation limited to the white substance of the spinal-marrow produced spasm only, without altering the sensibility, and that the posterior roots of the nerves of the medulla spinalis, are not destined for sensation, since the inflammation, by which they were affected, produced neither augmentation nor diminution of the general sensibility. Lastly, the inclination of the head to the right side appeared owing to the slight engorgement of the middle lobe of the right hemisphere of the cerebrum.

The pathological considerations are less important; however the author lays a stress on the presence of the worms in the jejunum; it is to them that he attributes the inflammation of the jejunum, which was, according to him, the primary point of nervous irritation, and afterwards of inflammation of the tunics of the spinal marrow.

The professor quoted a second case, the subject of which was a young man, who was attacked with lumbar pains, and permanent spasm of the flexor muscles of the trunk, but more particularly of the inferior extremities. Bellingeri stated this disease to be a chronic inflammation of the spinal marrow; the sentient system remained perfect, and under the antiphlogistic treatment the patient recovered.

Morbid affections of the spinal marrow can then produce permanent spasm of the muscles; and in the latter case, the spasm chiefly occupied the flexors of the lower extremities, and from the uncontrollable power of their movements, a superficial observer would have thought them in a state of paralysis, and he feels convinced that, in the majority of cases, what is called paraplegia does not depend upon defect in the nervous action, which engenders true muscular paralysis, but rather that the difficulty of movements is owing to predominant action of certain muscles over others, *which is an habitual state of spasm*. This condition is known by the rigidity the patient experiences in the affected muscles, and to a sensible hardness to the touch, whilst in paralysis the muscles are in a state of softness and flaccidity. This is a very important point to determine, especially if we wish to draw any physiological deductions from symptoms and autopsic examinations, it is essential to distinguish whether the affection be spasm or paralysis.

The opinions of Bell and Magendie, who state the posterior spinal nerves are the conductors of sensation, and the anterior the nerves of motion, are thus directly opposed by the experiments of the Italian physiologists, and, from the singular facts connected with the preceding case, it appears to us a point worthy of more minute investigation.

APOTHECARIES' HALL.

NAMES of gentlemen to each of whom the Court of Examiners granted Certificates of Qualification on Thursday, May 8th.

John Wale Bryant Ash	Bristol.
Francis Henry Marshall	Pitsford.
George Clippendale Richards	London.
John Rowley	Lancaster.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE XC., DELIVERED APRIL 18, 1833.

GENTLEMEN,—When a cataract is free from every complication; when it is not attended with frequent headach, nor pains in the eye; when the pupil retains its regular circular shape; when the iris possesses its natural power of motion in the different degrees of light; and when the patient can readily discern the difference between light and darkness, and even perceive bright colours, and the outlines of objects, in shady places, where the pupil naturally expands,—the prognosis is favourable.

We have no medicines nor applications capable of dispersing an opacity of the lens, or its capsule. The cases, injudiciously blended with the subject of cataract under the name of *false cataracts*, which are only obstructions of the pupil by lymph, effused in consequence of inflammation, may sometimes be benefited, or even cured, by the means which I recommended in speaking of iritis; but no real analogy exists between such cases and opacity of the lens and its capsule. In all examples of true cataract, it is only by an operation that sight can be restored.

Whether an operation should be performed when the cataract is single, and the other eye in the enjoyment of good vision, is a question on which some difference of opinion is entertained. Diversity in the refracting powers of the eyes after the removal of the lens from one of them, and the apprehension of confused vision, as a result of the operation, are the reasons usually urged against the practice, which, however, has, to a certain extent, at least, proved successful; while the continuance of a cataract in one eye not only gives a disposition to the origin of the same kind of opacity in the other, but permanently impairs the sensibility of the retina itself for want of exercise.

VOL. V.

It is a general rule, gentlemen, and I believe an excellent one, never to operate upon both eyes at the same time. In particular, when extraction is to be done, this maxim is universally adopted. It is also a maxim to let the patient have the benefit of preparatory treatment before he undergoes the operation. His diet should be lowered and his bowels emptied.

In cases of congenital cataract, you may inquire, ought the operation to be delayed till the patient has attained the age of docility and reason? Or ought it to be practised in early infancy? Every consideration seems, I think, to be in favour of an early performance of it. If it be postponed, the eyes, having no distinct perception of external objects, acquire such an inveterate habit of rolling, that, for a long time after the pupil has been cleared by an operation, no voluntary effort can control this irregular motion. The retina, too, by a law common to all structures of an animal body, for want of being exercised, becomes more or less deprived of power. From the age of 18 months to two years is deemed an advantageous period for operating on congenital cataracts.

Gentlemen, I will next mention to you a curious fact:—Persons blind from congenital and other cataracts of long duration, and habituated to live with four senses, are generally confused and perplexed on the restoration of vision. They have a difficulty in combining the action of the eye with that of the other senses. Hence Dupuytren has often found it necessary to deprive them, for a time, of the use of one or two of the other senses, in order to enable them to use the organ of vision. He has applied this principle to infants, by closing their ears, as it was noticed that they suffered themselves to be guided by sound, and by impressions received by the hands, which they thrust out before their bodies like tentacula.

Gentlemen, there are three kinds of operation for the cure of cataract. 1st. The method formerly termed *couching*, and which is simply the removal of the cataract out of the axis of vision, leaving it still in the eye. It is now frequently called *displacement*, and has two

L L

varieties, *depression* and *reclination*. 2nd. Surgeons practise *extraction of the cataract*; that is, they take the opaque lens completely out of the eye. 3rd. Another method often adopted consists in the *division of the cataract into fragments*, which, being exposed to the aqueous humour, become absorbed.

By *depression* and *reclination* you change the situation of the cataract. In *depression*, the lens is pushed directly below the level of the pupil. In *reclination*, the lens is made to turn over into the middle, and towards the bottom of the vitreous humour, so that the surface of the lens, which was previously directed forwards, is now placed upwards, and what was the upper edge is turned backwards. Over the lens, displaced in this manner, the vitreous humour will close much more completely than over the simply depressed lens, so that its ascent behind the pupil again will be less likely to happen. Nor will the retina be so liable to be pressed upon by the cataract as after depression; yet, reclination unavoidably does more extensive injury to the hyaloid membrane of the vitreous humour.

Gentlemen, I may next observe, that *extraction* is the complete removal of the cataract out of the eye through an opening made in the cornea. The incision for this purpose must form the segment of a regular circle, be smooth, and, at the same time, of sufficient size to permit the easy passage of the cataract through it. Both in this first period of the operation, and in the subsequent one of opening the capsule, the iris should remain entirely free from injury.

One of the chief dangers of extraction is that of the loss of the vitreous humour, which, if due care be not taken, is apt to be suddenly forced out of the eye along with the cataract.

Another risk is that of the iris being wounded. Sometimes the operation is followed by a prolapsus of this organ, sometimes by a closure of the pupil from the inflammation excited in the iris by injury of its texture.

The *division*, or breaking of a cataract piecemeal, gentlemen, may be done with a needle, either through the sclerotica or the cornea. It has the recommendation of being the most easy, but sometimes needs repetition. Opaque portions of the capsule, however, frequently resist absorption, and must, after all, either be extracted or displaced. The division of a cataract, when performed by passing the needle through the cornea and pupil, is termed *keratonyxis*.

Gentlemen, it is now well ascertained, that no method of operating for the cure of cataract should be exclusively preferred; and that each has its advantages in particular cases.

Depression and Reclination through the Sclerotica.—Each of these operations has three stages.

In the *first*, the needle is introduced through the coats of the eye into the vitreous humour.

In the *second*, the instrument enters the posterior chamber, and is applied to the cataract.

In the *third*, the displacement is effected.

It is only in the third stage that reclination differs from depression.

The patient is generally seated on a low stool, with his head supported on the breast of an assistant, who stands behind him; and, if the operation be about to be done on the left eye, he puts his right hand under the patient's chin, while with the index and middle fingers of the left hand, applied to the margin of the upper eyelid, he keeps it raised against the superciliary ridge of the frontal bone, without making any pressure upon the eyeball itself.

The operator sits in front of the patient, on a seat of such height that the patient's head is opposite to his breast. If it be the left eye which is to be operated upon, he takes the needle in his right hand, while, with the left fore-finger, he depresses the lower eyelid, and at the same time puts the end of the middle finger just below the caruncula lachrymalis, so as to prevent the eye from rolling inwards.

1st Stage.—With the little finger resting on the patient's cheek, the surgeon introduces the needle one-eighth of an inch behind the temporal edge of the cornea, so as to avoid the ciliary processes, and one line below the transverse diameter of the pupil, so as to avoid wounding the long ciliary artery. For the purpose of avoiding the lens and ciliary processes more surely, the needle should be directed towards the centre of the vitreous humour, but only to the depth of one-fifth of an inch, as it would be wrong to injure the vitreous humour to an unnecessary extent.

Second stage.—One flat surface of the needle is now to be turned forwards, the other backwards, and its handle inclined towards the temple, so as to bring its point between the ciliary processes and the circumference of the lens.

The instrument is next to be carefully introduced between these parts into the posterior chamber, across which its point is to be conveyed, till it arrives behind the nasal portion of the iris.

Third stage.—When depression is the method chosen, the flat side of the end of the needle is now to be placed upon the upper part of the lens, the handle gradually elevated, and the point carried downwards, and a little outwards and backwards, the proper direction in which the lens should be depressed, but no further than is necessary to remove it from the axis of vision. The needle should be kept for a minute or two on the lens, and, before it is withdrawn, you should observe whether the cataract rises again.

Some operators turn the point towards the pupil, and move it freely in it, in order to be sure that the capsule, if left behind, will be so lacerated that it will give no further trouble.

When *reclination* is preferred, the surgeon alters the plan of proceeding in the third stage, and then, instead of placing the end of

the needle on the vertex of the cataract, he applies the instrument to its front surface, a little above its centre, and makes pressure on it downwards and a little outwards, by which manœuvre it is made to fall backwards, as it were, into the vitreous humour.

If displacement be attempted on a soft fluid cataract, no sooner is the capsule opened with the needle than its contents mix with the aqueous humour. In a day or two, however, this fluid will become clear again; but unless you break the anterior portion of the capsule, before you withdraw the needle, vision will still be interrupted by the capsular part of the cataract.

Gentlemen, let me next remind you that the *after treatment* is a business of considerable importance. The eyes are to be shaded by means of a light compress, pinned to the night-cap. The room is to be kept moderately dark, and a low diet and quietude strictly enjoined. After three or four days, a green shade may be put on; but the eyes are not to be used for at least a fortnight after the operation.

Extraction of the cataract through an incision in the cornea, gentlemen, is divided into three stages.

In the *first*, the cornea is opened with the knife;

In the *second*, the anterior layer of the capsule is divided;

In the *third*, the cataract is taken out of the eye, or extracted.

The eye to be fixed, as already explained; unless the surgeon choose to place the patient in the recumbent position, with the intention of dividing the upper segment of the cornea, while he fixes the upper eyelid himself; a plan now sometimes adopted, and which has its advantages.

First stage.—1. The point of the knife is to enter the cornea very near the sclerotica, and a little above the horizontal diameter of the cornea.

2. It is first to be directed rather towards the iris, until it reaches the aqueous humour, so that there may be no risk of its gliding between the layers of the cornea, and not entering the anterior chamber at all.

3. As soon as the point is in the anterior chamber, the handle is to be inclined backward, and the point directed towards the place at which it is intended to make it pierce the cornea on the side towards the nose.

This place should be rather above than below the horizontal middle diameter of the pupil, and very near the edge of the cornea.

4. Having performed the *punctuation* and *counter-punctuation* of the cornea, as they are termed, you will now have the eye completely under your control. All pressure at this particular period is to be removed, and therefore the finger placed on the caruncula lachrymalis may be shifted to the lower eyelid. The instant that the section is finished, the upper eyelid is to be allowed to fall, the room rather darkened, and nothing more done

till the patient has had a short time given him to become composed again.

Second stage.—For opening and lacerating the anterior layer of the crystalline capsule, a lance-shaped, sharp, double-edged needle, such as I now show you, is the best instrument. The assistant is very cautiously to raise the upper eyelid, without touching the eye in the least. The operator draws down the lower eyelid, and presses it very gently against the eyeball, so as to make the cataract advance a little, and the pupil expand, but not so forcibly as to burst the hyaloid membrane.

The needle is then to be introduced under the flap of the cornea, and through the pupil to the anterior layer of the capsule, which is to be freely cut and torn in various directions; then the needle is to be withdrawn, and the eye again closed.

Third stage.—If the pressure made on the lower part of the eyeball in the second stage were continued, the lens would come out of the eye on withdrawing the needle; and many surgeons allow this to happen. Others let the pressure cease for a minute or two, and close the eye again after having divided the capsule.

They then take the curette in the hand, which held the needle, and having opened the eye, and renewed the pressure, they see the whole lens pass into the anterior chamber, and then through the incision in the cornea. The curette is only used, if necessary, to facilitate its passage through the wound.

The patient is now to close his eye again, and the operator, having received the lens on his finger nail, examines whether it is entire.

After having once more opened the eyelid, and ascertained that the sides of the incision in the cornea are accurately in contact, and the pupil clear and circular, the eyes are to be shut, a narrow strip of court-plaster put from one eyelid to the other; and over that a light fold of linen is to hang down from the cap, to which it is to be pinned.

The patient should afterwards be kept perfectly quiet, in a room somewhat darkened, with a nurse to watch him, so that he may not rub the eye with his hand during sleep. The incision may be looked at on the third day, and on the fourth the patient may be allowed to sit up. On the fifth a shade may be put on, but the eye should not be used for at least ten days, and then only on large objects. The bowels are not to be disturbed for a day or two after the operation, but the patient should be restricted to low diet for eight or ten days. If much pain and inflammation follow the operation, be sure to bleed the patient freely, and give calomel. When you attempt any proceedings through the pupil, you must not forget to dilate that aperture with belladonna.

The kind of operation to be preferred must depend upon the species of cataract, and the sort of eye which is to be dealt with. I put out of present consideration the difference of skill in different operators. No doubt, gentlemen, extraction is the right method, when the

cataract is hard, and the practice not contra-indicated by the cornea being remarkably flat, the iris too convex, the eyeball small, and sunk in the orbit, or the space between the eyelids very narrow.

When there are adhesions between the cornea and iris, or between the iris and the crystalline capsule, extraction should not be attempted.

A very small pupil, not admitting of being much dilated even by belladonna, would be another reason against extraction.

The operation of division is most applicable to caseous or fluid cataracts, and especially to such as occur in children. If the cataract were hard, but not proper for extraction, owing to the general form or state of the eye, depression should be practised.

The loss of the crystalline lens necessarily produces a considerable diminution in the refracting power of the eye, and in its faculty of adapting itself to the different distances of objects. These defects are palliated by the use of convex glasses of different foci. Their use, however, must not commence too soon after the operation, and never as long as vision continues to be improving without them.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XXII.

Pathology of Painters' Colic—Researches on the State of the Nervous and Digestive Systems—Treatment—Use of Narcotics and Purgatives—Efficacy of Tobacco—Treatment of the Gastric Complication—Paralysis—Mode of Pemberton—Use of Strychnine—Colic from Copper—Case of Mercurial Spasms—Affection of the Respiratory Muscles.

GENTLEMEN,—We were occupied at our last lecture in considering the symptoms of painters' colic. I mentioned that it occurs under a variety of forms; that the symptoms are to be attributed to a lesion of nervous function independent of any known organic change; and that the same disease may be seen in animals which have been exposed to the poison of lead. There are some other facts connected with this disease, which should not be passed over, and which I am anxious to lay before you previously to entering upon the treatment.

You will recollect that I introduced the subject by stating that painters' colic belonged to the class *neuroses*, and that I endeavoured to show that this implied a lesion of function of any part or viscus of the body, frequently characterised by the most decided departure from the natural condition, and yet unaccom-

panied by perceptible organic change. I said also, that it was hard to suppose the existence of great functional alteration, *without any molecular change*; but that, in the present state of science, we are compelled, for want of a better term, to call these affections *neuroses*, in contradistinction to diseases in which there is organic lesion visible. To illustrate this point, take an example from two different cases. In one case of what is called *dyspepsia*, we have inflammatory, or, at least, sub-inflammatory derangement of the stomach: here the disease is traceable to organic change; in another case we have symptoms of nearly the same character, and yet there is no organic lesion. Painters' colic comes under the latter head; we observe symptoms of excessive functional lesion, but dissection does not exhibit any organic change. Pathological anatomy tells us what it is not, and we arrive merely at a negative knowledge of its nature. We have decided proofs of extraordinary lesions of the nervous system, and yet, when we come to the post mortem examination, we cannot find any visible change to account for these striking phenomena.

The old pathologists maintained, that spasm of the intestines was the principal cause of the disease, and attributed the symptoms to their contraction. This opinion appears to have some foundation, when we consider the violent symptoms of colic which accompany this affection. Dubois de Rochfort has mentioned, that in such cases he has found intus-susception of the intestines. De Hean says, that contractions of the colon are very common; and several authors make the same assertion. The results of more modern observation, however, are against these opinions. I have told you already, that, in consequence of this disease seldom or never proving fatal, there is a degree of doubt attached to its pathology; but it is an interesting fact, that where death, from other causes, has occurred during the existence of painters' colic, the digestive tube has been found either in its healthy state, or with a few detached spots of vascularity, without any decided inflammatory character, and totally insufficient to account for the symptoms. This, which is all that pathological anatomy reveals, may be considered as purely accidental, and only of occasional occurrence, so that we are compelled to look upon the disease as one in which there is great lesion of function without any organic alteration.

In the hospital of La Charité, at Paris, a vast number of cases of painters' colic have been treated. In the space of eight years five hundred cases of this description have been admitted; out of these, five died while labouring under the disease; and the following is an abstract of the appearances observed on dissection. In the first case, there was rupture of an aneurism of the abdominal aorta, and the patient sank from loss of blood. On examination, the digestive tube was found in the natural and healthy condition—there was

neither *vascularity* nor *contractions*. The subject of the second case died of apoplexy. The whole intestinal canal was found healthy, and, contrary to the doctrines of the school of Broussais, there was neither congestion nor vascularity. In the third case, the patient had fits of an epileptic character, in one of which he expired. The colon exhibited a slight degree of redness, but quite insufficient to explain the symptoms during life. In the fourth, the cause of death was the same, and, on dissection, the tube was found healthy. Another patient, after recovering from the symptoms of painters' colic, got a sudden attack of asphyxia and died. His body was examined, but there was no trace of disease in the colon or any other part of the intestinal canal. Here we have five cases in which there was either no disease at all in the digestive tube, or, if there was any, the amount was quite insufficient to account for the symptoms. Louis, in a memoir which he has published, on sudden and unexpected deaths, gives a case of this disease where death occurred suddenly on the eighth day. The intestines were found to be in a healthy condition. Martinet gives two cases of persons who died of the cerebral symptoms while labouring under this disease: here, also, the tube was in the normal state. Thus we have eight cases with dissections detailed by various authors, all men of high professional celebrity, having no theory to support, and all agreeing in the statement, that there is little or no appreciable lesion of the digestive tube; that in the majority of cases it is in a state of health; that no contraction exists; and that such morbid appearances as have been found must be looked on as accidental.

There is one interesting circumstance in these cases which deserves to be noticed. With the exception of the first and fifth cases, all the patients presented that form of the disease in which the functions of the brain are decidedly injured. Here it seems probable that the cause of death was excessive irritation of the nervous system. Now, in the observations I made on the cases, which were treated at the Meath Hospital, you will recollect I stated, that where the cerebral symptoms were predominant the abdominal were more or less indistinct and latent, and that the cause of indistinctness, or even total absence, of these might be owing to the force of the disease being thrown upon the brain and spinal cord. Such was the case in the instances above recited, and such we have also seen to be the result in the case of those animals of an inferior order, that have been exposed to the poison of lead. How far the predominance of cerebral excitement may explain the want of appearances of disease in the digestive tube may be a subject of consideration.

What is the state of science with respect to the brain and spinal marrow? Allow me here to call to your recollection the symptoms of functional derangement of the nervous centres, the coma, the violent convulsions, the

amaurosis, the deafness, the delirium, the paralysis. All these are violent symptoms, and you would naturally expect to find them connected with some sensible alteration, some congestion, or inflammation, or ramollissement. But nothing of this kind can be discovered. In all the cases, where death occurred under such circumstances, at La Charité, with the exception of some slight appearances of cerebral lesion in the second, there was no perceptible disease in the brain, or spinal cord. The membranes and substance of the brain presented their normal condition; there was little or no fluid in the ventricles; the spinal cord was healthy and natural in consistence and colour, and there was no effusion into its sheath. All these circumstances led to the conclusion that painters' colic is essentially a neurosis. Observe, too, how interesting it is to connect the circumstance of the absence of organic change, with the singular fact which I mentioned in my last lecture, that the comatose symptoms of this affection may be treated with stimulants and opiates. Where we have coma with congestion of the brain, opium has the effect of increasing the symptoms; here it was found to have a contrary effect. So that our experience and the results of pathological anatomy, as far as they go, appear to square exactly. We see, then, that painters' colic is not inflammation of the intestines, or of the brain, or of the spinal cord, and this information, though of a negative character, possesses considerable value in a practical point of view. I do not know any case of what have been termed neuroses, in which the bearings of pathological research on practice are so extensive and so satisfactory.

It is a fortunate circumstance that this disease is seldom fatal, and it is some consolation to think that, although the patient's sufferings are dreadful and often protracted, there is little danger of life, and that the complaint is almost always amenable to judicious treatment. I have been for some years in the habit of treating it in a routine way, and can speak from experience of its success,—of course this treatment is to be modified by circumstances. Suppose a patient applies to you with violent pain about the navel, a hard and retracted state of the abdomen, obstinate costiveness, and the other symptoms which characterise an attack of painters' colic; the first thing I would advise you to do is to prescribe a full opiate. Many persons would object to this, and say that there is constipation enough already, and that opening the bowels would be much more likely to give relief. But opium does not here add to the constipation; indeed, so far from doing this, it sometimes acts as a laxative. At all events, it is a remedy which is perfectly unobjectionable. Give, then, in the first place, a full opiate, it will have the effect of relieving the patient's sufferings, and will enable you to gain time for the employment of other means. The next thing is to place the patient in a hip-bath, and keep him in it as long as possible.

Do not neglect this, for I know of nothing that gives more decided relief. I have often seen cases where the patient was quite easy while he remained in the bath, but experienced a return of the pain as soon as he left it. If you have no means of procuring a bath in this way; the next best thing is to have recourse to emollient stupes containing some narcotic, after the manner first introduced by my colleague, Dr. Graves. One of the best of this kind is the tobacco stupe, if you cannot get this you may employ poppy-heads for the same purpose. The tobacco stupe is much better than the tobacco injection, because its effect can be more easily regulated, but in violent cases I am in the habit of combining both, employing the stupe during the paroxysms of pain and throwing up a tobacco enema every four or six hours, until a decided impression has been made on the symptoms. In the success which has attended my distinguished friend Dr. O'Beirne's treatment of tetanus by the use of tobacco we see an analogous effect. In this way you will succeed in giving relief; you should also prescribe a brisk cathartic, and this you may do without any fear of injuring the patient, or exciting intestinal inflammation. The insensibility of the intestines to the stimulus of even powerful purgatives is a curious feature in this disease, and bears strongly against the idea of its being connected with any inflammatory condition of the tube. In the Hospital La Charité the treatment is routine; it consists of an emetopurgative plan, which is continued day after day until the symptoms yield. The purgative we employ in the Meath Hospital is croton oil, combined with castor oil and mucilage, or given in the form of pill. When the bowels have been freely acted on, the case generally goes on well. After the bowels have been opened, we continue the employment of the hip-bath, the narcotic stupes, and anodyne injections, taking care at the same time to persevere in the use of purgatives.

Andral makes a good remark on this point. "Here (says he) are cases in which, from some peculiar alteration in the state of innervation, the mucous surface of the bowels is rendered less sensible than in its ordinary condition, and can bear freely the stimulus of powerful purgatives. May not this condition also occur in other states of the economy? We are, therefore, led to conclude that purgatives are not, in all cases, direct stimulants."

Painters' colic has been treated in Paris by bleeding and leeching, but this has not been found so successful as the ordinary purgative plan. I have never seen a case in which general bleeding seemed to be called for except one, and this was a most violent case which had resisted the ordinary means of treatment for forty-eight hours. I recommended bleeding from its well known antispasmodic power; a quantity of blood was taken, and soon after the purgatives began to act, and the patient got relief. With respect

to leeches, I have employed them only in those cases which are accompanied with symptoms of fever and gastric irritation; where there is quick pulse, hot skin, foul tongue, thirst, vomiting, and epigastric tenderness. In such cases I have applied leeches, but my experience of them is, that the relief afforded is by no means so great, or so decided, as in cases of intestinal inflammation, and it is a mode of treatment which I do not by any means rely upon for removing the disease.

After the violent symptoms have been subdued, the next thing you have to consider is, whether there is any paralytic affection, and how this is to be treated. If the disease be severe or of considerable duration, you may look for paralysis of one or both of the upper extremities with a good deal of certainty. This part of the subject, I believe, more properly belongs to the consideration of nervous affections, but, as I have gone so far into the treatment of painters' colic, I may as well give the whole together. The paralysis which follows this disease is different from that which is the result of apoplexy; it is a neurosis of the passive kind, and to be treated as such. The patient, some time after the occurrence of the usual symptoms of colic from lead, begins to complain of weakness in his arm, he feels some difficulty in extending his fingers or raising his hand to his head, and then the symptoms become more marked. The arm and fore-arm become rapidly atrophied, the paralysis principally affects the extensors, while the flexors retain a considerable share of power, the fingers are bent, and the arm hangs by the side. Here the first thing you should do is to adopt the treatment recommended by Dr. Pemberton in his work on Abdominal Diseases, namely, to apply a splint to the inside of the fore-arm and hand, so as to counteract the preponderating influence of the flexors. Apply a splint to the fore-arm, wrap it up in flannel, and make the patient keep it supported by a sling. In this way you establish a kind of balance between the antagonist muscles, and place the extensors under favourable circumstances for bringing about a cure. If the patient has both arms affected, which is sometimes the case, change the splint from one arm to the other every second day, and continue this alternation until the cure is completed.

You will next have recourse to the use of strychnine, one of the best remedies we possess in cases where the paralysis does not depend upon organic disease of the brain. This is a remedy which is given with good effects even in cases of paralysis from apoplexy, *where there is reason to suppose that absorption of the clot has taken place*. In a case of apoplexy, it can be employed only after some time and where depletive measures have been sedulously put in force, but in a paralysis of this description you may begin with it at once. Commence with the exhibition of one-twelfth of a grain of strychnine two or three times

a-day, and go on increasing the dose gradually, until a grain, or even a grain and a half, is taken in the twenty-four hours. To ensure the exact division of this powerful drug, you should direct a grain of it to be dissolved in a few drops of alcohol, and then made into pills of an equal size with crumb of bread or conserve of roses. In this way you will succeed in bringing back the lost power of the muscles of the fore-arm and restoring its nutritive functions. I may mention here, that the atrophy of the paralysed limb, which occurs in this disease, cannot be accounted for by supposing that it is produced by want of exercise; the emaciation is so rapid (sometimes taking place in ten days or a fortnight) that we can only attribute it to some unknown lesion of innervation.

If the use of strychnine be followed by severe muscular twitches, pain in the head, or convulsions, you must omit it for some time, and then, when these effects have completely subsided, it may be resumed if necessary. You should also bear in mind, that this remedy is one of those medicines which have been termed accumulative, that is to say, a patient may be taking it for a considerable time without any perceptible symptom, and then its effects explode suddenly, the quantity which has been accumulating in the system manifesting itself at once by symptoms of great intensity. Here you omit it immediately, and with a view of relieving the existing symptoms, prescribe a draught, composed of camphor mixture, ammonia, and opium. This has generally the effect of calming the nervous excitement and you will seldom have any more trouble on this account. *En passant*, I would advise you, whenever you employ strychnine in private practice, to inform your patient of the occurrence of such symptoms, and tell him that there is no cause for alarm. Instead of strychnine, some of the continental practitioners are in the habit of prescribing brucine, and it is stated with considerable advantage. I have tried it in two or three cases without much apparent benefit, and I am inclined to think that it is decidedly inferior to strychnine. In France, however, it has been very largely employed, and has the reputation of being a remedy of considerable value in the treatment of paralysis. It has one advantage at least over strychnine, it can be much more easily divided and regulated, so far as respects the quantity given, as it is a much weaker preparation than strychnine, one grain of which is equivalent to six grains of brucine.

In addition to these measures, I have seen much benefit result from the application of blisters and frictions, with stimulating liniments to the spine. It is also of importance to remove the clothes in which the patients have worked; they are frequently charged, saturated with lead, and have a considerable tendency to keep up the disease. I have so often seen an attack of painters' colic reappear

shortly after leaving hospital, and without any evident exposure, that I could only attribute it to the circumstance of their garments being saturated with the lead.

In the foregoing plan of treatment there is nothing new; it is, in fact, a routine practice, but it is one which is borne out by the results of pathology, and which, from long experience, I can strongly recommend. I may also remind you that the plan of treatment followed in the Hospital of La Charité, which has more cases of this disease than any similar institution in Paris, is completely routine.

Other metals besides lead, as, for instance, copper, produce effects somewhat analogous. Copper is said to produce salivation, colic, and vomiting. Brass-founders are liable to these symptoms, as also other persons employed in the manufacture of copper. I have not seen the disease, but it is said to be analogous to lead-poisoning, so far as colic is concerned; in other respects the symptoms differ. The convulsions are not so violent, nor is the paralysis nor coma so frequent; there is often considerable fever, thirst, difficulty of respiration, præcordial anxiety, diarrhoea, and prostration of strength, so that it comes much nearer to ordinary intestinal inflammation with fever, than painters' colic. Yet it is a curious fact, that, notwithstanding all this array of symptoms so closely bordering on inflammation, it has been found in Paris, where several cases of this disease have been seen, that it is amenable to the same treatment as painters' colic, and that, under the use of purgatives, the fever, thirst, diarrhoea, and tenesmus subside.

Mercury, under certain circumstances, will produce a most extraordinary affection, on which I shall here make a few observations. The disease is not of very frequent occurrence, but it is of importance in practice to be able to recognise and treat it properly. It is a proposition well known to almost every one, that a many bad effects have resulted from the abuse of mercury; and I need not tell you how many persons are injured by the empirical employment of this potent drug on all occasions and in all constitutions. It is a common opinion that mercury acts principally on the capillary and absorbent systems, but there can be no doubt that it also acts upon the nerves, and that in a very remarkable manner. I have seen cases where the constant use of calomel has produced a marked derangement of the nervous system, manifested by great irritability, tremors, hysterical excitement, and hypochondriasis. You will see in the various works on Toxicology an account of the effects produced by mercury on persons employed in quicksilver mines, and on tradesmen, such as looking-glass manufacturers and others who come in contact with mercury. I shall read for you the notes of a remarkable case of this kind, which was some time back under treatment in the Meath Hospital. It may be called a form of the paralysis agitans from the

effects of mercury. Similar cases have been described.

A man, aged forty-six, was admitted into one of our medical wards in October 1833.

He stated that, from the time he was eight years of age, he had been employed in a looking-glass manufactory, and that his occupation principally consisted in what is technically termed the silvering of mirrors. In this process the operator's right hand is repeatedly immersed in a vessel filled with mercury, while the left fixes a sheet of tin-foil, on which the metal is rubbed. Artisans while thus engaged are in the habit of using a muffle, which covers the mouth and nostrils. This the patient said he had never used, because he found that those who were in the habit of wearing it did not enjoy better health. For thirty years he continued to enjoy tolerable health, with the exception of some bleeding from the gums, with shooting pains and a sense of formication in various parts of the body, accompanied by a slight loss of power in the hands, which came on at various times, and was generally relieved by the use of ardent spirits. He had been frequently salivated, and when admitted had lost nearly all his teeth. The mode in which he lost them was this, gum-boils formed close to the roots of the teeth, which soon after dropped out, and in this way the local inflammation subsided. About three years ago, he had an attack similar to that for which he had been admitted; he went into the hospital and was put under an active antiphlogistic treatment with relief. From that time up to the period of his admission, he had enjoyed tolerable health, except that the sight of the right eye was considerably impaired, and that his memory was slightly affected. He forgot the names of persons and places, and was frequently at a loss in endeavouring to recollect the persons to whom he had lent his tools. On being brought into the hospital, he presented an extraordinary specimen of human suffering, and I was at first unable to give his complaint a name, the case being the first of the kind I had seen. It exhibited the phenomena of a violent spasmodic affection; it was different from tetanus, or hydrophobia, or hysteria, but it bore some faint analogy to chorea. The head, arms, and fingers, particularly on the left side, presented a succession of quick, convulsive, jerking motions. The angles of the mouth were retracted, the eyebrows twitching, the head constantly thrown back, but the agitation scarcely raised the arms. The nostrils were spasmodically dilated. The sterno-mastoid, trapezius, scaleni, diaphragm, and the abdominal muscles were similarly affected. Their contractions were short, rapid, and painful. From the constant hiccup with which the spasms of the diaphragm were attended, and the jerking motions of the tongue, his speech was interrupted and indistinct. He was occasionally free from spasms altogether, but whenever he transmitted volition to any part of the

muscular system, it became instantly affected. When he endeavoured to raise his foot from the ground, it quivered and fell quite powerless and useless. Whenever he attempted to carry a vessel to his lips, he generally overshot the mark, carrying the vessel towards his ear, nose, or forehead, and spilling its contents over his face or neck, so that it was a common saying among the patients in the ward, that he did not know the way to his mouth. But if a vessel was applied to his lips by another person, he could swallow easily. A sudden blast of cold air, the application of a cold hand to the skin, or the abrupt entrance of any person into the wards brought on an attack of spasms. The muscles of the left hand and of the left side were affected much more than those of the right. The mental powers were not impaired, the patient was intelligent, and seemed anxious to communicate the particulars of his case. During the whole course of the disease he retained a full power over the urinary discharge and defecation. There was some slight tenderness on pressure over the fourth and fifth dorsal vertebræ, but the rest of the spine exhibited no increase of sensibility. His skin was cool and dry, his pulse quick, weak, and small, his bowels inclined to be costive, but easily moved by laxatives. Here we see a marked difference between this affection and painters' colic.

The treatment adopted in this case was very simple. Leeches were applied to the tender part of the spine, the patient was placed in a warm bath, and got some laxative medicine, followed by an opiate. He was also ordered to have a large flannel shirt, and to be placed in a warm comfortable bed. He passed the night tolerably well, and next day appeared to be much improved. I shall not continue the daily reports of this case, but shall merely mention, that after a few days a great improvement took place. The spasms of the left side continued, though much less severe. Those of the purely voluntary muscles on the right ceased, while the spasms continued in the respiratory muscles on this side. We found that all the muscles of the face which have been called respiratory by Sir C. Bell, the platysma, scaleni, pectoral, and intercostal muscles, and the diaphragm, were thrown into violent spasms, while the purely voluntary muscles remained in a state of perfect quiescence. I am not aware that this circumstance has been observed in any other case. As far as it goes, it tends to corroborate the views of Sir C. Bell. In the treatment of this case we employed narcotic frictions, particularly those composed of the extract of belladonna, to the spine with considerable benefit. The patient was cured by very simple means, and at little expence to his constitution.

HOPITAL DES VENERIENS.

OF THE COMPLICATIONS AND OF THE
TREATMENT OF BLENNORRHAGIA
IN WOMEN.

BY PHILIPPE RICORD, D.M.P., &c., &c.

*Translated from "The 10 sous Journal des
Connaissances Medico-Chirurgicales" for
November, 1833.*

BY ALEX. THOMSON, M.B., OF ST. JOHN'S CAMB.

(Continued from page 369, Vol. IV.)

WHATEVER may be the cause producing blennorrhagia in the woman, that affection may present different complications, of which some belong to all its forms, while others are the consequence of its virulent nature. I am about to enumerate, in its turn, each of these complications, dwelling chiefly upon the most important.

1st. A complication, generally not very serious, but very inconvenient and frequent, particularly in fat women, is *intertrigo*, erythema of the external parts of the great labia and the internal part of the thighs. Frequently the matter of an abundant and acrid discharge, joined to fatigue and uncleanness, determines this complication. I have seen in some patients, who are in the habit of much neglecting themselves, these parts affected with erysipelas, with eczema, or with herpes. There are some in whom the integuments of this region, by means of a kind of mucous transformation, furnish a muco-purulent secretion, analogous to blennorrhagic matter, and thus give rise to a kind of extra-genital blennorrhagia. Such an affection, more frequent when there are about to supervene mucous papulae, and which most commonly is only in some measure the first degree of them, is most frequently accompanied with a disgusting odour, quite peculiar and characteristic, when the mucous papule exists.

2nd. The different parts composing the vulva may be affected with oedema. I have shown, in my clinical lectures, instances very curious in this respect. Sometimes the nymphæ alone have been attacked: there existed, in those cases, a species of phymosis; at other times, the great lips being affected at the same time with the small, the latter have undergone a strangulation more or less powerful, and comparable to a true paraphymosis. A young woman still occupying the bed No. 35, of my first Women's Ward, presented us a very remarkable example of this. This oedema of the genital parts, which likewise occurs under other circumstances, but which is seen rather frequently in simple as in virulent blennorrhagia, may terminate in a speedy and complete manner, or else pass into a state of induration more or less difficult to overcome, or even be complicated with erysipelas, or terminate by suppuration or gangrene.

3rd. With blennorrhagia phlegmonous inflammations at times supervene. Hence the frequency of abscess of the great lips. In some cases I have seen abscesses supervene in the perinæum during a blennorrhagia. In one patient with a most acute blennorrhagia, an abscess was developed in the clitoris, the supuration was very abundant, and a part of the prepuce was destroyed by the force of the inflammation alone. A number of women have cysts, more or less voluminous, in the substance of the genital lips; these cysts may remain for an indefinite period without being changed; but, under the influence of mechanical or other excitations, or as a consequence of acute blennorrhagia, they are inflamed, suppurate, and give rise to an abscess, which, when it opens spontaneously, or when a small aperture is made in it, tends unceasingly to be reproduced, or to be transformed into a fistula, which most frequently is only to be cured by an operation.

4th. The inflammation of the urethra may extend to the bladder; indeed I have frequently seen cystitis and vesical catarrh complicate blennorrhagia in the female, or be in some measure but an extension of that disease. Accompanying the same, I have more generally observed *dysuria*, or even complete retention of urine, sometimes depending upon the excessive inflammation, sometimes on a state purely spasmodic, or, finally, occasioned by these two causes united. In some rare cases the patients have voided blood with the urine; there has been *hæmaturia*.

5th. Buboës come sometimes to complicate blennorrhagia in women, and most particularly when it affects the urethra. Produced by sympathetic irritation, or depending upon successive inflammation of the lymphatics, from the inflamed surface to the most adjacent gland, it may be developed in every form of blennorrhagia, and assume different seats, as I shall hereafter mention in a special article upon buboës. But a constant fact, which I ought here to call to mind in investigating bubo as a complication of blennorrhagia, is, that whatever may have been the intimate nature of the discharge when there have not existed true chancres, never have the suppurated buboës furnished a pus susceptible of being inoculated.

6th. If we seek the complications from the uterus and its appendages, we find in some patients aberrations of the menstrual discharge, some being seized with amenorrhœa, while in others there supervenes true metrorrhagia. These cases are rare, it must be confessed, but nevertheless they exist. In a young chlorotic patient under my care at the Hôpital des Vénériens, the blennorrhagia appeared to have brought back the menses, which, up to that time, had not come as a consequence of all the emmenagogues that had been employed. Sometimes women of a very nervous temperament have been subject to frequent attacks of hysteria during the progress of a uterine blen-

norrhagia, or else in them this affection has been complicated with true metritis. But what I have already twice had occasion to observe, there are, as complications, some symptoms which may be referred to as an inflammation of the ovaries, similar, in this case, to the inflammation of the testicle in man. A patient lying at No. 6 of the second Women's Ward of my service, aged 32 years, affected with a very acute urethro-genital blennorrhagia, was seized suddenly with a sense of tension in the iliac fossa of the left side. The touch, which yielded distinctly the sensation of a tumefaction, occasioned much pain, and I could appreciate in that spot an increase of temperature; there supervened some nausea and a febrile movement, with fulness of the pulse; the patient remained lying on the back, and, from preference, inclined to the left side, with the thighs a little bent upon the pelvis. The discharge from the urethra, and from the genital parts, had almost entirely disappeared. On touching, by the vagina, the following is what I was enabled to determine. Pressure of the neck of the uterus, by the indicator finger, was not painful, while pain was produced when the finger, placed upon the left side of the womb, tended to push the organ back towards the right iliac fossa, by exercising a sort of tension upon the left broad ligament; the same manoeuvre, practised upon the other side for the sake of comparison, produced scarcely any uneasiness; defecation, emission of urine, and in general all the abdominal movements were painful. These symptoms, combated by antiphlogistics, disappeared towards the twelfth day, and, in proportion as they lost their intensity, the discharge became more and more abundant; when suddenly the discharge diminishing anew, the same series of phenomena were manifested, but this time on the right side. I have, again, at present at No. 2 in the first Women's Ward, a patient, in whom the pupils attending my clinical lectures have had an opportunity of verifying a case almost similar, to that which I have just related; yet, in this second observation, the left side has alone been affected.

7th. Mucous papules, or pustules, a frequent consequence of virulent blennorrhagia, may be regarded as complications; the same is true of divers kinds of vegetations, many of which are altogether independent of all virulent principle. As to chancres, distinct from blennorrhagia, and due to another kind of contagion, they may exist at the same time with this and complicate it; they may, by means of irritation of the parts adjacent to their seat, determine alone discharges, or keep them up, without these discharges being of a nature similar to the pus they secrete.

8th. Blennorrhagic ophthalmia, and arthritis, disturbances of the circulation, of the innervation, of the digestion, of the urinary secretion, &c. may occur as accidents, or as complications of blennorrhagia.

9th. Finally, it must not be forgotten that

in this, as in all other diseases, the duration of the particular cause of the evil is a troublesome complication.

Passing now to the history of the treatment of blennorrhagia, whatever may be still its particular cause, its essence, its intimate nature, and its complications, or accidents, it does not less appear with the characters of catarrhal inflammation, acute or chronic, and as such calls for the treatment of inflammations in general, less subject, perhaps, in the woman than in the man, to abrupt displacement, or to metastases, having nothing to be feared from its rapid cessation by delitescence; it would doubtless be very advantageous to be able to produce its suppression at its origin. But hitherto it must be confessed there is no efficacious and certain method of obtaining this happy result; and if sometimes the production of suppression of discharges in man is successful, from the use of revulsives applied to the digestive tube, by copaiba taken at the commencement of the disease, by astringent, irritant, and even caustic injections into the urethra; these means in the woman remain most frequently without influence, or aggravate the evil in the greater number of cases.

Yet, in the impossibility of procuring the arrest of blennorrhagia in women, care must be taken in its treatment to fulfil exactly the indications, and not to lose sight of this principle, that the more recent the blennorrhagia the more easily can it be cured, if it be well treated; while the cure of it will become more difficult when it shall have passed into the chronic state, and when it shall, in some measure, have established a right of domicile by altering the tissues. In the treatment of the affection under notice, the cause producing it, and capable still of keeping it up, must be removed, the most perfect continence must be enjoined, all irritating contacts must be avoided, and the organs of generation must be kept in the most complete state of repose; all cause of excitation of the adjacent organs must be avoided; the bowels must be kept relaxed by diluent drinks, such as veal-tea, whey, barley-water, sweetened with honey; and emollient injections, frequently repeated, must be employed in order to avoid the accumulation of faecal matter in the rectum. The urine must be rendered more watery by a sufficiently great quantity of drink; this is a very important point, but one which is not well comprehended by all medical men; indeed, they appear most frequently to seek to increase the secretion of the urine, and hence its excretion, to desire to make their patients make water more frequently. But this idea is false and injurious, particularly in the case of urethral blennorrhagia in the male and in the female, for if it were possible for the patients to remain for a very long time without discharging urine, the inflamed surfaces, deprived of the irritant influence of the urine, would certainly become better; likewise, never do I see in the treatment of a discharge,

administer diuretic medicines, such as nitrate of potassa, or others, I give the preference to mucilaginous decoctions, sweetened with syrup of orgeat, of currants, or of lemons. The object here, I repeat, is not to increase the secretion of the urine, but only to render that liquid less irritant by increasing its watery principles. Baths in blennorrhagia are extremely useful, and that, perhaps, more so in women than in men; but the preference must be given to entire baths, recommending the patients to take them of a very moderate temperature; too hot or too cold they are no longer appropriate; their temperature must be graduated, not by the aid of the thermometer, but rather by the sensations of the patients taking them, so that when they are in the water they may be neither hot nor cold. When the contact of a foreign body is not very painful, when the introduction of the pipe of a watering-pot syringe does not induce suffering in the vulva, I recommend, during the bath, vaginal injections, frequently repeated, with the water itself of the bath. Independently of baths, which are taken every day, or every second day, according to the necessity, the patients, who must as much as possible remain in a state of repose, inject themselves every morning and evening with a mucilaginous injection, such as the decoction of the marsh-mallow-root, or of linseeds. These injections, which ought not to be made, as I have already stated, except when the introduction of the syringe does not produce too much pain, must also be had recourse to in such a manner that they may remain for a short time in the vagina. To obtain that, the patient, couched upon her bed, elevates the seat, or, seated upon a chair, places the legs upon something more elevated than the seat upon which she is sustained. These precautions having been taken, the injection must be pushed slowly. In some patients the pain is greater than the inflammation seems to warrant in these cases. Independently of the opiates and antispasmodics that may be administered in lavements or by the mouth, one finds considerable advantage in adding to the emollient injections some poppy-heads, or some of the plants of the *solanum montanum* (*Morelle*). But a means of the greatest importance, and which should never be neglected, is the continuous application of the simple or the narcotised emollients I have just indicated; indeed, in spite of the precautions taken, the liquids injected do no more than pass over the diseased surfaces, and then act only as a means of cleanliness, without having the time to operate a medicamental effect. To be more efficacious, plugs of linen ravelings (*charpie*), or fine sponges must be imbibed with them, and introduced into the vagina, and allowed to remain there. I ordinarily have an injection made, and then I cause to be introduced into the vagina, and as far up as to the neck of the uterus, the plug of linen ravelings imbibed with the liquid of the injection, and

attached to a thread that hangs out of the vulva for the facility of withdrawing it. The plug should be sufficiently long to occupy the whole length of the vagina, and not sufficiently bulky to distend it, which would be productive of irritation. Once it is placed, as it must have lost from compression a certain quantity of the liquid with which it was charged, I cause a new injection to be made upon it, which it in great part retains. This plug is renewed twice in the four-and-twenty hours. At the hospital a small entire speculum of M. Recamier is made use of in order to place it; and, in the cases in which the introduction of the speculum produces pain, the patients introduce it themselves with the finger, which is very easy to be done, and even in these cases preferable, for then the women have need of no one to dress them. But the means I have just indicated, and which are applicable in all the cases, allowing for the appropriate modifications, do not alone suffice when the blennorrhagia is intense, or when it is complicated; indeed, when the inflammation is vivid, blood-letting becomes necessary. Bleeding of the arm is very useful in women who are strong, and who, moreover, have a slight febrile reaction. In the commonest cases, leeches, in number proportionate to the power of the patient and the violence of the affection, should have the preference. I have them applied in the fold of the thigh whenever there are no chancres, for there is then no fear of ulceration of the bites as a consequence of inoculation. But in the case in which chancres exist, leeches should no longer be placed upon a part dependent and susceptible of being touched by the pus, which might transform their bites into true chancres.

If the menstrual discharge supervene during the progress of a blennorrhagia, it should momentarily replace artificial blood-lettings, which should be only practised, if needful, after the menses have ceased to flow. Moreover, during this period, the injections may be continued, but the plugging should be suspended.

The different complications of blennorrhagia I have indicated yield to the above treatment, or else, if they resist it, or if they become intense, then forming in some measure a separate disease, and independent of the blennorrhagia, their peculiar treatment must be applied to them, into the details of which I cannot enter in this article.

But blennorrhagia in the woman, as in the man, does not always yield to antiphlogistics the most judiciously applied, and most commonly then other means must be resorted to. Copaiha may be employed for it; but it must be confessed that it is far from having the almost specific virtue it has with the man. I have very frequently employed it for all the forms, and in varied doses, alone, or mingled with cubebs, and rarely has it produced, in a clear manner, effects similar to those observed in the male sex. Its most evident and most

efficacious action is manifested in cases of urethral blennorrhagia of the woman, cases which have the greatest analogy with blennorrhagia in men, in which this medicine is advantageous.

However, the copaiba acts in one sex as in the other in two different manners, at first upon the digestive passages, of which most frequently it disturbs the functions by determining, in doses relative to the individuals taking it, more or less frequent stools, and then upon the urinary organs, by increasing sometimes the secretion of the urine, but by always communicating to this fluid its characteristic odour, and consequently a part of its principles, which come to act directly upon the diseased urethral mucous membrane. The vagina and the womb, placed in a *juste milieu* between the rectum and the urethra, seem by their position to escape from this last action of the copaiba, since under its influence the urethra recovers, while the vagina and the uterus still furnish their morbid secretion. So the copaiba and its succedanea, the cubebs, turpentine, &c., succeed sometimes in suppressing urethro-genital discharges; I scarcely insist on their employment, except in the cases of blennorrhagia of the urethra in the woman, preferring rather, as soon as the diminution of the inflammation prescribes it, to have recourse to astringent or resolute plugging. Indeed, as soon as the acute stage diminishes, as there is no more pain, the emollient injections and the emollient pluggings are abandoned, and replaced by injections and pluggings of another nature. Injections and pluggings with the concentrated solution of the acetate of lead succeed the most frequently, and I give them the preference in most cases. When the patients are still very near the acute state, I employ the following solution:—

Common water, a pound,

Crystallised acetate of lead, half an ounce.—Mix them together.

When the patient is altogether in the chronic state, the dose of the acetate of lead is increased to an ounce for the same quantity of water. The injections, moreover, are renewed twice a-day; at the hospital there is but one dressing in the twenty-four hours. After the injection, the ravelled linen, steeped in the same liquid, is introduced into the whole length of the vagina, and allowed to remain, care being taken to make thereon a new injection, as in the case of the employment of emollients, which I have already indicated. It is important to remark here, that in some patients, without determining the least pain, and when the discharge has entirely ceased, some points of the vagina or of the neck of the uterus become excoriated under the influence of the too concentrated acetate of lead. Then it must either be weakened or completely suspended. For a hundred women affected with blennorrhagia, sixty are cured by the means I have just indicated,

in twenty days, a month, two months, or still later. In others who have resisted anti-phlogistics and the employment of the acetate of lead, and in whom the disease has passed into the chronic state, lesions of tissues that must be combated are found by the aid of the speculum; sometimes they are vegetations of the vagina, or of the neck of the uterus, which must be cut out or cauterised; at other times they are granulated or prominent ulcerations, having the aspect of a suppurating surface of a blister, or else hollow ulcerations, that must be locally attacked, and which are the cause of the persistence of the discharges. If these diverse ulcerations are still accompanied with acute inflammatory symptoms, or if the patient have actually her menstrual discharge, or expects it soon, I still cause the emollient injections and plugging to be continued. In the contrary circumstances, all the granulated and prominent ulcerations, and those of which the aspect resembles the surface of a blister in a state of suppuration, are touched, after having been laid bare by the aid of the speculum, with a small brush of linen ravelings steeped in acidulated nitrate of mercury. Unless the prominence be very considerable, the cauterisation must never be very profound, one must content oneself with whitening the surfaces, taking care to make the caustic bear upon the diseased points. To that end all the affected parts must be previously wiped, and the mucus, which would otherwise alone be cauterised, removed by the aid of a long dry charpie brush. But the very tenacious mucosities, especially that coming from the interior of the uterus, yield with difficulty to the action of the dry brush. To remove them perfectly, they must in some cases be previously coagulated by the aid of the acidulous nitrate itself, and then they may be extracted in concrete morsels with the greatest facility, and the cauterisation of the parts they cover may be affected. Cauterisations thus made never produce either pain or accident; upon more than six hundred women, whom I have subjected to it, and who have owed their cure to it, there are at most seven or eight who have felt something, without, however, suffering; the others did not even know they had been touched. Immediately after the cauterisation, I place a plug, imbibed with the solution of acetate of lead, which is subsequently renewed twice a-day, the injections being made as has been indicated above. The cauterisations are moreover repeated every seven or eight days as long as necessary, care being taken to graduate their intensity according to the particular aspect of the ulceration, and in reference to the results of antecedent cauterisations, they requiring to be so much the stronger, in proportion as the tissues appear softer, of a more dull greyish-white, and more prominent.

The ulcerations hollow beneath the level of the adjacent parts, whatever may be their presumed nature, sometimes yield and cicatrise

under the influence of cauterisation with the acidulous nitrate of mercury, like the former; but in a great number of cases, the cauterisations appear to keep them up, or to increase them. When neither emollient nor narcotic applications produce their cicatrisations, when they have resisted the solution of acetate of lead, and the acidulous nitrate of mercury, I place upon them some calomel prepared by the aid of vapour, by means of a brush made of ravellings of linen, placing subsequently into the vagina a plug of dry linen ravellings. In some cases, moreover, of profound ulcers, which had likewise resisted this last means, the cure has been effected by the application of Narbonne honey mingled with a twelfth part of proto-ioduret of mercury. By aid of these means, I have been able to cure a great number of patients that hitherto had been regarded as incurable, and there are scarcely any but those affected with degenerated or carcinomatous ulcerations, that have not yielded to these modes of treatment; but these last cases have been very rare. Upon the great number of patients I have had to treat in the course of two years at the hospital, I have but twice practised amputation of the neck of the uterus, in cases of fungous cancer.

Yet in some patients, without there having been very marked, or even appreciable, alterations of tissue, discharges have still been able to persist. Most commonly they have for seat the deep parts of the vagina, the neck of the uterus, or the uterine cavity, these parts being cured neither so well, nor so quickly, as those in contact with the air, or placed more exteriorly.

Yet in these cases, plugging with dry charpie, or the introduction of the air, by means of a gum elastic perforated speculum left in the part, injections, and plugging with solution of the sulphate of zinc, with chlorine water, with pure wine, or the vinous decoction of Provence roses, with the solution of corrosive sublimate, with decoction of oak bark, of sulphate of alumine, the diluted tincture of iodine, the acidulous nitrate of mercury diluted, &c., employed by turns, have sometimes succeeded; the employment of purgatives, of blisters to the inner parts of the thighs, to the hypogastric and sacral regions, and vapour baths, have likewise sometimes yielded fortunate results; but in these obstinate cases no indication should be neglected; the use of bitters, and of astringent tonics, and of iron in particular, is very favourable in weak, lymphatic, and scrofulous women; as also sulphurous remedies, Barège baths, injections, and plugging with Barège water, in psoriatic women.

I have, it must be confessed, seen these means be much more efficacious in the particular case I have just indicated, than the use of mercurials, the action of which is very weak or wanting in the greater number of patients, in whom there exists nothing but a discharge; and it is only when there are other symptoms, that its employment with me finds a motive

and appears efficacious. In the discharges coming from the interior of the uterus, and which are due to some slight or deep alteration of its mucous surface, a local medication is likewise required as for the vagina and the vulva; for as medications applied upon the vulva would do nothing for the deep-seated parts of the vagina, so medications placed in the vagina have little or no influence upon the uterine cavity, and they must, therefore, be introduced into that cavity. I have been able by means of injections of a solution of acetate of lead practised every day, in the intervals between the menstrual periods, to destroy chronic uterine discharges. In two cases of patients markedly lymphatic, and even scrofulous, very abundant whites have yielded to uterine injections made with the following solution:—

R. Distilled water, three ounces,
Tincture of iodine, one drachm. Mix them together.

If one would obtain some advantage from this treatment, it must be continued very carefully.

In some patients who have exhibited ulceration of the os tincæ running into the cavity of the womb, and of whom the uterine secretions have been purulent, I have attempted cauterisation of the internal surface of this cavity. To this end, I have had constructed a syringe with a double cylinder, of which the pistons worked singly, and which enclosed in one of its cylinders acidulous nitrate of mercury, diluted with twelve parts of distilled water, and in the other pure water. Its pipe, also double, is adaptable to a gum elastic catheter, of about eight inches in length, which, opened at its two extremities, and smeared with a greasy body, is introduced into the uterus. The injection of the acidulous nitrate is then pushed gently, and in small quantity, to the extent of about a small teaspoonful, and after having allowed it to remain for a minute or two, the watery injection is then pushed on. Five patients affected with very abundant purulent uterine discharges, and which had resisted all other means, have been thus treated and cured in my clinical service at the Hôpital des Vénériens. I should state that I have only employed this means as a desperate remedy, and with all possible precautions, and that although I have never had any troublesome cases, in some patients it has produced accidents of short duration, but formidable in appearance, having determined, in the greater number, instantaneous and very violent hysterical attacks; which, by the way, would tend to support the opinion of those who place the seat of that disease in the womb.

However, when I have obtained the cure of a blennorrhagia in a woman, whether there does or does not remain a mucous discharge, I recommend the habitual use of injections of cold water, once or twice a-day, and that by commencing eight days after the cessation of the menstrual discharge, to stop again eight days before its arrival, and recommence afterwards

in the same manner. By following this practice, the cures have appeared to me to be more substantial, and the spontaneous relapses less frequent.

ON THE CAUSE OF DEATH IN ASPHYXIA.

BY DAVID WILLIAMS, M.D., LIVERPOOL.

As the Editors of a distinguished medical publication, I deem it necessary to address you on a subject, that has not only reference to myself but in some respect to medical literature. Presuming it likely, that the work on the Physiology, &c., of Asphyxia, just published by Dr. Kay, of Manchester, may be reviewed in your Journal, I am desirous of putting you in possession of certain circumstances connected with his subject. I may remark, though familiar to you, that, until lately, Bichat's views of the nature and cause of asphyxia were considered the most probable and best established, hence they were those that were taught and admitted in our colleges and medical writings.

In a paper, On the Cause and Effects of an Obstruction of the Blood in the Lungs, published in the 19th volume, 1823, of the Edinburgh Medical and Surgical Journal, I have given an account of a series of experiments which I had performed. From phenomena, which were witnessed in these experiments, I deduce:—that the obstruction of the blood in the lungs, on suspension of respiration, is not the effect of a mechanical cause, that is, of collapse, or subsidence, of the lungs; that the obstruction of the blood in the lungs, on suspension of respiration, arises from a deprivation of pure atmospherical air. From these deductions and the facts, that an animal can survive only a very limited time the suspension of the function of respiration, and that the blood undergoes a wonderful change in consequence of its being acted upon by the inspired air, I infer, “that the blood cannot pass from the system of the pulmonary artery into that of the pulmonary veins, without first undergoing those unknown changes from the action of the inspired air.”

In my paper, I have noticed that Harvey supposed the circulation, in asphyxia, to be arrested in the lungs; Goodwyn and Bichat in the heart; that Harvey attributed the vacuity of the aortic system, after death, to an obstruction of the blood in the lungs, in con-

sequence of their collapse; that Goodwyn and Bichat concurred in imagining asphyxia to be immediately dependent upon the circulation of black blood, or blood of a venous character,—the left ventricle, according to Goodwyn, ceasing to act “from a defect of a stimulating quality in the blood itself,”—the heart ceasing to act, according to Bichat, from the circulation of black blood (*sang noir*) in the coronary arteries, this fluid stopping (*empêche*) the action of its fibres. The error of these several views I have pointed out; and, in conclusion, I have advanced the theory—that the immediate cause of the cessation of the action of the heart, on suspension of respiration, arises from the obstruction to the circulation in the lungs: not from a state of collapse of these organs, as supposed by Harvey, but from a deprivation of pure atmospherical air. Further, I have cursorily examined how the obstacle to the circulation of the blood, from the deficiency of pure atmospherical air, is adequate to explain the cause of some of the vital phenomena observed in health and disease.

My paper, as I have above stated, appeared in the 19th vol. of the Edinburgh Medical and Surgical Journal for 1823. In the 29th vol. (1828) of the same Journal, Dr. Kay published an essay, entitled “Physiological Experiments and Observations on the Cessation of the Contractility of the Heart and Muscles in the Asphyxia of Warm-blooded Animals,” in which he develops the same views, with respect to the immediate cause of the cessation of the action of the heart, as I had already done by a similar or analogous series of experiments. In this essay no reference is made to my paper, which had appeared, in the same Journal, four years previously. This circumstance I mentioned to Dr. Kay. In 1831, Dr. Kay published “Further Experiments on Suspended Animation” in the North of England Medical and Surgical Journal. In this essay, in a marginal note, Dr. Kay says that I had called his attention to my paper, and states my having anticipated him in one of his conclusions, namely—“That the obstruction of the blood in the lungs, on suspension of respiration, arises from a deprivation of pure atmospherical air.” This marginal note is copied into Dr. Kay's recently published volume on the Physiology, &c. of Asphyxia. However, though Dr. Kay enters very elabo-

ately into the history of asphyxia in this volume, yet no notice whatever is taken of my having questioned the correctness of Bichat's hypothesis, or of my having advanced the theory, "that the immediate cause of the cessation of the action of the heart, or asphyxia, on suspension of respiration, is the effect of the circulation being obstructed in the lungs.

I regret that any circumstances should arise to render it imperative on me to make this communication. But, in consequence of the author of the article on asphyxia in the *Cyclopædia of Medicine*, and the reviewers of Dr. Kay's recent work in the *Liverpool Medical Journal*, having given Dr. Kay exclusively the credit for being the first who pointed out the errors of Bichat's hypothesis, and established that the immediate cause of asphyxia is the obstruction to the circulation in the lungs, I deem it incumbent on me, in my own defence, to set the profession right on those points. Should the subject of asphyxia be hereafter reviewed in your *Journal*, I trust the reviewer will take the trouble of examining the papers alluded to, and thereby satisfy himself of the truth of this statement, and do justice accordingly.

Liverpool, May 12th, 1834.

Foreign Medicine.

ACADEMIE DE MEDECINE.

Sitting, April 29th, 1834.

President—M. LISFRANC.

Spontaneous Evolution of the Fœtus in case of Arm Presentation.

M. VELPEAU introduced the subject of the terminations of labour complicated with presentation of the upper extremity. The opinion that in certain cases this species of accouchement could terminate without manual assistance, has met with some opposition; facts, however, have confirmed it, the birth taking place by the breech or the head. Half a century ago Denman stated that the fœtus could make its exit by the head, whilst the arm presented. M. Velpeau, as well as others, have seen cases confirming this assertion. The practice formerly employed tended to bring on such a termination. Fabrice de Hilden mentions a case in which the fœtus was pulled

by the arm; and adds, that his wife, who was a midwife, always adopted this course. Generally, however, these labours terminate by a birth of the breech. It had been tried to explain this by saying that the breech descended because the chest ascended, which explanation had been generally adopted. It has, however, been contradicted lately by Guillemot, who maintains that the arm does not ascend, and that the breech nevertheless comes down. A few days since M. Velpeau was called to a case of arm presentation, in which all attempts of inversion had been fruitless, the uterus contracted with violence and very frequently; the hand of the operator could not be carried into the cavity of the pelvis, and the shoulder, already, with part of the chest, were in the vagina; the arm, which was black, swollen, and livid, projected outwards. Instead of making repeated trials, M. Velpeau waited patiently. The abdomen, then the hip and pelvis, successively escaped, and the child was born without the arm having moved. A similar fact has been noticed by M. Perrot, in which case the breech escaped. Numerous other cases might be mentioned. From these facts it may be seen that, in cases of arm presentation terminating by the breech, the fœtus does not undergo evolution, but unrolls, as it were. This is not so extraordinary as it might at first seem; for, the acromion and the clavicle pressing against the side of the inferior circumference of the pelvis, all the force of the contractions bear upon the breech, the body being alone able to yield, the chest and abdomen are driven down, and the breech is expelled, because it offers less resistance than the head. The practical results will be, that when the arm presents it will certainly be better to endeavour to bring down the head or the feet; but when the shoulder is protruded, and the uterus forcibly contracting, in which case the fœtus is generally dead, it would be, perhaps, more proper to favour spontaneous evolution, than to bruise the parts by painful manœuvres.

M. Capuron.—The possibility of birth by spontaneous evolution has never been contested. That which remains to be known is, if spontaneous evolution be profitable to humanity, and if we must wait for it when the arm presents. If we wait long the fœtus will

putrefy, and then that part which yields first will carry down the head with it.

I was called some time since to a case in which the shoulder presented, but no attempts had been made to hasten delivery. A jingling noise was heard suddenly, and the child fell on the floor. It is not difficult to conceive spontaneous evolution to take place when women have been fatigued, and putrefaction has commenced in the foetus. M. Velpeau does not mention the size of the children in the cases he has described. In all those I have seen they were small, the head was soft, and they were still-born. The question is, whether, in practice, we must wait for this evolution or not. Now, when the shoulder is protruded, the hand cannot be introduced; if you leave the patients to nature, you would have utero-peritonitis from putrefaction of the foetus, and contusion of the parts. The shorter plan would be, to draw down the shoulder, and to extract the child. Nothing, then, has been done for science, in omitting to explain the dimensions of the children.

M. Villeneuve.—The observations made by M. Velpeau appear to me important; for to this day, spontaneous evolution in cases of arm presentation have been considered of very rare occurrence. I have only seen one example of it, in which I had not been able to invert the child; the pains were moderate, and I left the patient at two o'clock in the morning, at four she was delivered of a child of large size, which was her first.

M. Moreau.—The facts mentioned by M. Velpeau are very common, and known to all obstetricians; with regard to their explanation, that given by Denman was not, it is true, sufficient, but others have rectified it. M. Velpeau has omitted to say, that in spontaneous evolutions the foetuses might be small, still born, or putrefied. Ought we to adopt the precept, to wait for the evolution? No; it can only be considered as a fortunate occurrence, but far from establishing a rule. When the shoulder is protruded, if the patient be left she is exposed to death, the foetus swells, putrefies, and gases are disengaged. I have seen a case in which the child was very large, the liquor amnii had been expelled, and the acromion presented at the external orifice of the vagina was livid and distended; the hand could not be introduced. Blood-

letting and fomentations were prescribed. I saw her again some time after, putrefaction had made some progress, and the genital organs were slightly relaxed. I was then enabled to introduce my hand, and produce the inversion. The putrefaction was such that I was attacked with erysipelas of the arm in consequence: it would have been better to have dismembered the child, and extracted it sooner.

M. Velpeau in reply observed, I am of the same opinion as my colleagues in the principal point, but I have not completely treated the question. M. Capuron says, that in spontaneous evolution foetuses are generally small and still-born; this is usually the case; but Denman and others mention children who were born at the full period, and weighing nearly six pounds; and there are six or seven authenticated cases in which the children were alive. I have not said that we should either assist or wait for the evolution; when inversion is possible, doubtless we should attempt it, but when otherwise, we should perhaps endeavour to assist the evolution.

Bilious Epidemic at Limoges.

We extract the following from an interesting paper communicated to the *Gazette Médicale* by M. Voisin, surgeon to the central penitentiary of Limoges.

The house of detention at Limoges is situated in a meadow at the south-east of the town, about two hundred yards from the river, and thirty feet above its level. This spot is extremely damp, often obscured till nine or ten in the morning by a dense vapour, which has collected during the night. The atmosphere is so cold, that it is only on the brightest days of summer that the genial influence of the sun's rays can overcome its baneful effects. Cold and humidity are the predisposing causes of suppression of transpiration, and the exciting causes of that long train of diseases, distinguished by the several appellations of enteritis, colitis, dysentery, intermittent, typhoid, and bilious fevers. As for the predisposing causes, these are of a local nature, such as confinement, melancholy, debility, profligacy, each of which by itself would have little influence, but becomes, when combined with others, a powerful agent. All these are to be met with in their worst forms in the Penitentiary of

Limoges. In the months of October and November, the number of patients increases rapidly; every autumn bringing in its train an epidemic affection, attacking principally the chylopoietic viscera. This year (1833) however, we have had bilious fever, instead of the usual intestinal disease. M. Voisin attributes this anomaly to the medical constitution of the year. The warmth and dryness of the summer, the bad quality of the fruit, have doubtless contributed to the prevalence of the influenza. Many patients, at the close of this disorder, have had their memories impaired to an extraordinary degree, in others the generative system has more or less suffered. The same effects have been observed after attacks of the bilious fever. A few cases of the latter had occurred during the summer in the neighbourhood, they increased in number in the month of September, at which time the intermittent fever of the country generally becomes prevalent. This month was very cold and wet; in October after the continuance for several days of southerly winds, the bilious epidemic was ushered in, and lasted as long as the wet weather, which prevailed for seven days, bringing on, at its termination, dysentery and erysipelas; up to this time, men only had been attacked. After four days of fine weather, a southerly wind returned, and with it rainy weather; the women now became affected, and the number of cases gradually increased. Generally speaking the worst cases of an epidemic happen at its commencement, it was not, however, till the close of this, that it was complicated with pneumonia, pleuritis, enteritis, &c., &c. In this manner the disorder continued through the whole of its course, increasing when the weather was cold and damp, and sensibly subsiding at the recurrence of an amelioration in the state of the atmosphere.

We will here detail some of the most prominent cases furnished by M. Voisin, to explain the characteristic symptoms of the different stages and varieties of the disease.

First, as an example of the bilious fever in its simple state, we shall notice the case of the woman Vrilette, unmarried, aged 31, of sanguineous temperament, who was seized, the afternoon of the 27th of October, with shivering, followed by heat, pain in the forehead, and in the epigastric region, loss of appetite,

disagreeable taste in mouth; continual nausea, especially after eating; no thirst. During the four succeeding days, there was progressive increase of these symptoms, with shivering and sleeplessness at night. Every day at noon exacerbation with shivering and heat.

On the 1st of November, greenish hue of the skin, and of the sclerotic coats of the eye; pain on pressure in the epigastric region; tongue pasty and white; very little fever; skin natural; urine high-coloured and clear; bowels open; respiration easy. (Sulphatis sodæ, ℥iiss., antimon. tart. gr. iss., misce; decoction of barley and liquorice, *ad libitum*; fever diet.) M. Voisin here remarks that antim. tart. is the only catharto-emetic he has employed during the prevalence of the epidemic.

Nov. 2nd.—Yesterday she vomited much bile, and had several stools; she perspired in the night, and slept in the morning. Shivering followed by diuresis, after which all the symptoms disappeared.

Bilious Dysentery—Gangrenous Erysipelas of the Face—Death.

Etier, convict, came into the infirmary the 18th of September, *facies hypocratica*; skin natural, but rather dry; no fever; tongue natural; belly drawn inwards; tenesmus, diarrhoea, continuing night and day; stools foetid and bloody, consisting of fluid with white flocculent matter on its surface; no loss of appetite. This state lasted till the 15th of October, notwithstanding the application of leeches to the anus, the use of opiate and astringent injections, of opium internally in all its forms and in large doses, emetics, strict attendance to diet, and warm baths.

On the 15th an erysipelas of the face made its appearance; diarrhoea had diminished. On the 16th, abundant discharge of yellowish serum from the eyes. 17th. Whitish eschars on the left upper eyelid; return of dysentery. 21st. Gangrene of the left eye; the patient discharged by stool an enormous quantity of foetid bilious matter. A little broth was allowed. He died on the 23rd at four o'clock, A.M., after having been delirious all night.

Autopsy.—Ecchymosis on the anterior surface of the left thigh and dorsum of the foot; muscles slightly discoloured and infiltrated; stomach filled with thick bile; small intestines healthy; colon and cæcum inflamed and ul-

cerated, especially the latter at its lower extremity; spleen three times its natural size; inflammation at the base of both lungs; circumscribed abscess between the superior lobe of the right lung and pleura.

Bilious Catarrhal Fever—Diarrhoea—Dropsy—Death.

The woman Poumeyret, aged 25, sanguineous temperament, a convict, entered the infirmary Sept. 30th. She had suffered from retention of the menses, brought on by grief in consequence of her detention. For the last fortnight she had every day an accession of fever, coming on at 5 P. M. and lasting till midnight. Twenty grains of the sulphate of iron were exhibited on the day of her admission, which checked the paroxysms; but, about the 4th of October, she complained of shivering in the back, coldness of the feet, pain in the head, anorexia, bitter taste in the mouth, dry cough, want of sleep, pain in the epigastrium; the skin was of natural temperature, respiration easy, but there was a greenish hue of the eyes and face; fever inconsiderable; tinnitus aurium.

Oct. 5. The same symptoms; nausea.

Antimon. tart. gr. jss,

In a five-ounce mixture.

7th. Has had bilious vomiting and diarrhoea. Disappearance of the other symptoms.

From this time she became gradually better, recovered her appetite, and was able to get up, but the greenish hue of the face still remaining, the decoction of cinchona was prescribed on the 13th. On the 17th, bilious diarrhoea, which continued till the 20th, when it gave way to opiate injections. On the 24th, return of appetite; still much debility.

28th. Ascites was discovered; there had been suppression of urine and perspiration for the last four days. The patient could only lie on the left side. Hydro-thorax.—Decoction and tincture of cinchona persevered in.

Nov. 2. Return of diarrhoea, diuresis; belly less distended; anasarca diminished; tongue dry; left side dull on percussion.—Decoction of cinchona and oxymel scillæ.

3rd. Expectoration of pinkish sputa; pulse small and frequent; tongue dry and pasty; diarrhoea; great oppression; voice nearly extinct; decubitus on the left side; skin cold; died the next morning.

Autopsy.—Thorax.—Left side filled with yellow serum; lung extremely contracted; the superior lobe was affected by tubercular pneumonia; incipient vomicae were found about its apex; right lung healthy; pericardium filled with serum. *Abdomen.*—Intestines floating in fluid; liver and spleen adherent to the diaphragm, both surfaces of which, as well as the peritoneum, were studded with miliary tubercles; inner surface of stomach coated with viscid mucus, streaked with blood. The venous system of the abdomen, especially that of the stomach, were distended with dark blood; ileum contained much bile, in a pure state, and was slightly ulcerated at its termination. The remainder of the intestinal canal contained nothing remarkable.

Catarrhal Bilious Fever—Diarrhoea—Latent Pneumonia—Typhus—Death.

Brunette, a woman, 23 years of age, of bilious temperament, had suffered for three weeks with evening exacerbations, lasting sometimes all night, and even continuing some part of the morning; pain in the arms and legs; severe headach; greenish hue of the face; tongue greenish and pasty; bitter taste in the mouth; anorexia and vomiting; pain under the right breast; slight cough; pulse slightly quick; urine of a saffron hue; stools natural. (Twenty leeches to the scrobiculus cordis, and fever diet.) This antiphlogistic treatment was persevered in for four days, but instead of diminishing the severity of the symptoms, tended rather to increase it. (Gr. ij antimon. tart. to be taken in three doses, at intervals of half an hour.) This produced vomiting of bilious matter in enormous quantities, it also acted on the bowels, and in a short time all the symptoms disappeared. On the sixth and seventh the affection again increased; antiphlogistics were had recourse to but without effect; small doses of tartarized antimony were then administered, and for a short time the patient felt a little relieved. On the 10th, latent pneumonia was discovered, other symptoms remaining much the same. The tartar emetic was from time to time administered, with some slight temporary relief. On the 19th diarrhoea supervened, the patient continued to lose power, the pulse became rapid, and on the 21st she died.

Autopsy.—Pneumonia of both lungs, which

were considerably infiltrated; there were traces of inflammation in the bronchi, but not in the trachea. The superior lobe of the left lung was adherent to the pleura. *Abdomen.*—Stomach contained a quantity of viscid mucus, but there were no signs of inflammation, although the patient had taken twelve grains of emetic tartar. The mucous membrane of the intestinal canal was in a state of congestion; towards the extremity of the ileum some of the follicles of Brunner were inflamed, there were also extensive ulcerations in the neighbourhood of the ileo-cæcal valve; the mesenteric ganglions were of a pinkish hue; spleen larger than natural.

THE LEEDS MEDICAL SCHOOL.

ON Monday last the annual adjudication of prize medals and certificates of honour to the pupils of the Leeds School of Medicine, who had distinguished themselves in their late examinations, took place.

The lecture room of the school was crowded on the occasion. After a few prefatory remarks by the President, the sealed papers, handed by the pupils, containing the names of the successful candidates, were opened, and the following contains a statement of the distribution of the medals and certificates of honour:—

ANATOMY, PHYSIOLOGY, AND PATHOLOGY.

Medal—Mr. J. B. Wood.

Certificate of Honour—Mr. Wm. Ainley.

PRINCIPLES AND PRACTICE OF SURGERY.

Medal—Mr. Samuel Hey.

Certificate of Honour—Mr. B. Addison.

MATERIA MEDICA AND THERAPEUTICS.

Medal—Mr. R. W. S. Hopper.

Certificate of Honour—Mr. Skilbeck.

CHEMISTRY.

Medal—Mr. William Ainley.

Certificate of Honour—Mr. Gibson.

PRINCIPLES AND PRACTICE OF PHYSIC.

Medal—Mr. H. Keyworth.

Certificate of Honour—Mr. Wm. Ainley.

FORENSIC MEDICINE.

Certificate of Honour—Mr. Wm. Ainley.

MIDWIFERY AND DISEASES OF WOMEN AND CHILDREN.

Medal—Mr. Sagar.

Certificate of Honour—Mr. R. W. Hopper.

The medal is a beautiful specimen of art,

executed by Wyon. On one side it presents the effigy of John Hunter, the great founder of modern pathology; on the other, a laurel wreath, surrounded by the designation of the school "Schola Medicinæ Leodiensis." The answers returned by all the pupils to the questions proposed were most creditable to their ability and acquirements, and reflect high honour upon the school, of whose efficiency they may be considered as the first substantial fruits.

On Wednesday the pupils entertained the teachers at Scarborough's Hotel. Nearly forty gentlemen sat down to an excellent dinner, Mr. Charles Chadwick in the chair; Mr. Graham acted as vice-chairman. Several appropriate speeches were made, the utmost enthusiasm and good feeling prevailed, and the evening altogether was spent in a very rational and gratifying manner.

UNIVERSITY OF LONDON.

ON Friday, the 16th inst., the Earl of Durham, supported by the Lord Chancellor, the Duke of Somerset, and nearly all the members of the Council, distributed the prizes to the medical students, in the presence of about 600 of the proprietors and friends of the University.

Dr. Elliotson, as dean, read the report of the proceedings of the Faculty of Medicine during the present session, and the following students then received prizes or certificates of honour from the chairman:—

PRINCIPLES AND PRACTICE OF MEDICINE.

Gold Medal—John Taylor, of Huddersfield.

Silver ditto—William Moorhead, of Duggan, Tyroneshire.
Ditto, ditto—E. S. Hare, of Yoxall, Staffordshire.

Certificates of Honour.

4. Joseph Humpage, of Bristol.
 5. Arthur Tibson, of London.

Equal } 6. Robert Marsh, of Bath.
 7. John B. Hodgson, of London.
 8. H. P. L. Drew, of London.
 9. William Robins, of Gloucestershire.
 10. John B. Peacock, of Chester.
 11. Edward Baker, of Birmingham.

ANATOMY AND PHYSIOLOGY.

Gold Medal—Edward Sellick Hare.

First Silver Medal—Thomas Bradshaw, of Huddersfield.

Second Ditto—William Moorhead.

Certificates of Honour.

4. Henry Walker, of Hampstead.
5. Thomas Morton, of Newcastle-upon-Tyne.
6. Joseph Humpage.
7. John E. Catley, of Cambridge.
8. C. Lingen, of Herefordshire.
9. Gay Shute, of Gosport.
10. T. F. Tyerman, of London.
11. G. S. Brent, of Southsea.
12. W. Kelly, of London.
13. Thomas Baskerville.
14. G. G. Holmes, of London.
15. P. B. Ayres, of High Wycombe.
16. A. Leggatt, of Guildford.
17. E. B. Walford, of London.
18. W. Acton, of London.
19. W. Lord, of Farringdon.
20. R. Wallis, of South Shields.

PRACTICAL ANATOMY.

Gold Medal—John Taylor.*First Silver Medal*—A. J. Dixon, of Hovingham, Yorkshire.*Second Ditto*—Thomas F. Tyerman, of London.*Certificates of Honour.*

4. W. Moorhead.
5. Edward S. Hare.
6. Thomas Bradshaw.
7. H. Walker, of Hampstead.
8. C. Lingen.
9. Robert Marsh, of Bath.
10. A. B. Cutfield, of Deal.
11. John E. Catley.
12. Thomas Morton.
13. W. Lord.
14. W. Kelly.
15. G. S. Brent,
16. Joseph Humpage.
17. Gay Shute.

MATERIA MEDICA AND THERAPEUTICS.

Gold Medal—Thomas Bradshaw.*First Silver Medal*—Frederick Cripps, of Wisbech.*Second Ditto*—Benjamin Clark, of Saffron Waldon.*Certificates of Honour.*

4. Thomas Haymes, of Leicester.
5. J. H. Rogers, of London.
6. C. Maitland, of London.
7. J. E. Catley.
8. W. M. Bush, of Clifton, Bristol.
9. F. Wakefield, of London.
10. J. Pranker, of Langport.
11. Thomas Paffard.

SURGERY.

Gold Medal—Thomas Lavery, of Manchester.*First Silver Medal*—William Moorhead.*Second Ditto*—Charles Nossoe, of London.*Certificates of Honour.*

4. Thomas Morton.

5. Francis B. Peacock.
6. John Taylor.
7. John E. Catley.
8. A. King, of Bridgewater.
9. G. Hill, of South Normanton.
10. Edward S. Hare.
11. William Robins.
12. Robert Wallis, of South Shields.
13. E. Jones, of Kynaston.
14. Thomas F. Tyerman.
15. John Davis, of London.
16. J. B. Shaw, of London.
17. E. Baker of Birmingham.

MIDWIFERY.

Gold Medal—W. W. Webb, of London.*First Silver Medal*—Edward S. Hare.*Second ditto*—John Taylor.*Certificates of Honour.*

4. Robert Marsh.
5. William Robins.
6. J. Douglas, of London.
7. F. R. T. G. Rodgers, of Windsor.
8. — — —
9. George Gill.
10. R. E. Edwards, of Lyme Regis.
11. H. Norton, of London.
12. W. Kelly, of London.
13. A. King.
14. Thos. Henry Cooper, of Lewes.
15. John Chippendale, of London.
16. Gay Shute.
17. John Thomas Darvill, of London.

CHEMISTRY.

Gold Medal—John P. Potter, of Nottingham, Kensington.*First Silver Medal*—Thomas Bradshaw.*Second ditto*—Philip B. Ayres.*Certificates of Honour.*

4. William B. Tegetmeir, of London.
5. Francis Wakefield.
6. Thomas Henry Cooper.
7. Arthur Tibson.
8. W. J. Hughes, of London.
9. Thomas Laycock, of Doncaster.
10. Edward D. Doughty, of London.
11. Henry Normansell, of London.
12. Thomas Baskerville.
13. Robert H. Semple, of Islington.
14. Thomas R. Hill, of Worcester.
15. William Hardwicke, of Lincolnshire.
16. Thomas Haynes, of Leicester.
17. E. J. Erichsen, of London.
18. Charles Dobson, of London.
19. Edward B. Baker, of London.
20. C. Robinson, of Bath.
21. John E. Catley.
22. Henry Walker.
23. Edward Hulme, of Bromley, Kent.
24. Frederick Cripps.
25. J. B. Shaw, of London.
26. Richard Nicholson, of London.

COMPARATIVE ANATOMY.

Gold Medal—Samuel Hadwen, of Lincoln.
Certificate of Honour—Kearsey Cannan, of London.

MEDICAL JURISPRUDENCE.

Prizes equal { John Taylor.
 { Thomas Henry Cooper.

Certificates of Honour.

3. R. C. Edwards.
4. Edward D. Doughty.

BOTANY.

Gold Medal—E. S. Hare.
Silver ditto—Alfred Leggatt.

Certificates of Honour.

3. Arthur Tibson.
4. Edward B. Walford.
5. Joseph White Holm, of Highgate.
6. William Acton.

KING'S COLLEGE.

THE distribution of the prizes at King's College, to the successful candidates in the School of Medicine, took place on Tuesday, 19th inst., in the lecture-room of the establishment. The seats were crowded with the parents and friends of the pupils. Amongst them were a great number of well-dressed females, who seemed to take a lively interest in the proceedings. At 2 o'clock, the hour which had been announced for the commencement of the business of the morning, his Grace the Archbishop of Canterbury, attended by the Bishops of London, Gloucester, and Chester, the Rev. Mr. Lonsdale, and several other clergymen, the members of the Council, the Principal of the College, and the Professors, took their seats. The prizes, consisting of gold and silver medals, certificates of honour, books, &c., were arranged on the table in front of the Archbishop, and were distributed to the candidates in the following order.

ANATOMY.—H. C. Metcalfe, the silver medal; Messrs. Young, Lee, and Park, certificates of honour.

PRACTICAL ANATOMY.—G. Galland, the silver medal; Messrs. Ward, Park, and Atkinson, certificates of honour.

FOR THE DISSECTION OF AN UPPER EXTREMITY.—Mr. Chance, 20 guineas.

BOTANY.—G. Cooper, the silver medal; Messrs. Smith, Baynes, and Cooper, certificates of honour.

CHEMISTRY.—W. H. Thornthwaite, the

silver medal; Messrs. Freeman and P. Margatson, certificates of honour.

MATERIA MEDICA.—Mr. Jones, the silver medal; Messrs. Baynes, G. Smith, and T. Symonds, certificates of honour.

MIDWIFERY.—W. B. Whitefield, the silver medal; Messrs. Park, Symonds, and Taylor, certificates of honour.

PRACTICE OF MEDICINE.—W. B. Whitefield the silver medal.

FORENSIC MEDICINE.—H. C. Metcalfe, the silver medal; Messrs. Orwin and T. P. Margatson, certificates of honour.

SURGERY.—Mr. John Simon, the silver medal; W. C. Robinson, certificate of honour.

The gold medals for general proficiency in medical knowledge were awarded to Mr. T. P. Margatson and Mr. H. C. Metcalfe.

The several Professors, Messrs. Mayo, Partridge, Burnett, Daniel, F. and B. Hawkins, Fergusson, Watson, Green, and Principal Otter, severally addressed the Chairman; they spoke in terms of great praise of the proficiency of the students, of the regularity of their attendance at the lectures, and the general propriety of their behaviour. The Principal Otter took occasion to eulogize the liberal and truly christian conduct of Sir Henry Worsley, K.C.B., who had made a munificent donation of 2,000*l.* to the College, for the purpose of educating and fitting out missionaries for the propagation of Christianity in the East Indies, and of Mr. Lethus, who had made a donation of 300*l.* to be invested in funds, and the interest applied to the purchase of prizes to be distributed to those pupils whose attendance at chapel, moral conduct, and progress in the knowledge of Christianity should be most eminent. The prizes, consisting of books, had been on the present occasion awarded to two gentlemen, who, in consequence of their not being aware of what was to take place, were not in attendance.

The Bishop of London, in an appropriate address, proposed a vote of thanks from the assembly to the Archbishop, which was seconded by a gentleman of the council, and carried by acclamation.

His Grace returned thanks for the honour conferred upon him,

After which the company broke up with feelings of high gratification.

THE
London Medical & Surgical Journal
Saturday, May 24, 1834.

PROGRESS OF PARLIAMENTARY IN-
 QUIRY—APOTHECARIES' HALL.

THE public is to be presumed unacquainted with the details of the proceedings before Mr. Warburton's Committee. This fiction in the law of publication, like many fictions in the common law, we must, as a matter of course, respect; and we are, therefore, compelled to abstain from printing that which every person may hear spoken if he pleases. We will not question the wisdom of the regulation under which our pages are closed against matter so interesting to the profession. Those who cannot avail themselves of the opportunity of listening to the original evidence, especially our friends out of the metropolis, must rely upon the wisdom and discernment of the active members of the Committee, that their long-entertained desires will not be frustrated;—that the whole and every part of the great question will be thoroughly examined;—that in its turn every separate province, which accident or convenience has made in the republic of medicine, will be minutely surveyed, and the relative effects of each on the others judiciously discriminated:—nothing less is worthy of the interests involved,—of the times,—of the excited anticipations of the medical public;—and perhaps the good seed we have had a hand in sowing among the public at large has already grown sufficiently to awaken its attention to the downright importance of the condition of the medical profession, in respect to the health of the state, and to interest it too in the results of the labours of the Committee. To persons possessed of this "eager hope,"

growing out of their "fond desire," (to invert the mental process of the poet,) it is enough to say, that we, who, as individuals, have free access to the inquiry, repose undoubting confidence on the result of the investigation—and that we are satisfied the evidence will furnish a complete account of the present state of the profession in every stage and in every condition. If the superstructure to be raised be not found large, solid, and commodious, the evil will not arise from an imperfect survey of the ground.

To persons who have occasionally been present we beg to address a few words. It is a very natural mistake for those to fall into, who take a deep interest in the result of a multifarious investigation, and think, in the pride of intellect, they have found out "the feature on which the question hinges," (to use the words of a celebrated prime minister,) it is, we repeat, a very natural mistake for such persons to fall into, if they are present at one stage only of the investigation, to conclude that the judge, or counsel, or committee, as it may be, is taking a partial or unsatisfactory view of the whole question. This distrust in the judgment of others is too flattering to our self-confidence not to be readily entertained. "Of all the flatterers," says Lord Bacon, "the arch-flatterer is a man's self." But it is nevertheless so fraught with injustice to others, and so mischievous withal, that, palpable as is the error, we must not therefore hesitate to unveil it in the case before us.

We are acquainted with several excellent persons, sincere friends of medical reform, who have fallen into the mistake we have noticed.

Of course the College of Physicians was entitled to precedence in the inquiry. Its assumed virtues, its denounced vices, equally established its right to that pre-

eminence. Would it not be rash to conclude, that the operations of the College at Lincoln's-Inn Fields were disregarded, because it remained at the back of the dock while the other stood at the bar? And, in like manner, in probing the ulcers of the latter, should the Committee be deemed inattentive, meanwhile, to the worst condition of the Hall at Blackfriar's Bridge? We agree with the persons we allude to in the opinions they entertain of the paramount necessity of examining into the state of pharmacy in these countries. That it is in a very deplorable condition it is impossible to deny, and it is moreover an undeniable fact, that the corporation, to whose care this interest is apparently entrusted, is, in point of numbers and of legal influence, the great medical corporation of the kingdom.—But let it not be too rashly concluded, that there is any novelty in this common-sense view of the relative importance of the three metropolitan corporations; or that the Committee is not sensible that the full investigation of the affairs of Apothecaries' Hall is a subject inviting its amplest powers, and upon the results of which every question that can be proposed in medical polity will in a great degree depend for its solution. This portion of the labours of the Committee is as yet scarcely touched upon, but we have no doubt that, when entered into, it will be elucidated in due proportion to its importance.

It matters little what medical skill we exact from the practitioner, if there can be no reliance upon the drugs he has to administer. In choosing the different sorts of teas there is no sacrifice of health, whatever there may be of taste, in following the injunctions of our pocket: it is very different in the case of medical agents, in which variations of flavour and

strength involve the medical properties for which they are used, and are of as much importance to the *vile body* of the poor man who is constrained to have recourse to them, as to the *sacred person* of his Majesty, with all the safeguards the law imposes on his physicians. In such articles it is absurd to talk of free trade. The wholesale trade in them is of necessity confined to a few persons. And it is beyond dispute that a powerful control over the market to exclude palpably inferior specimens should be placed in the hands of some proper authority. We conceive it would be well worth the attention of Government to establish a properly qualified pharmacist for this special purpose, whose salary—a liberal one—might be paid out of the revenue now raised by drugs; and we submit to the liberality of the Chancellor of the Exchequer, whether all taxes for any other than medical purposes upon medical drugs might not be repealed. We are aware it will be said the prime cost of physic, as increased by direct taxation, is a trifle compared with the retail price. It is so; but, at all events, we submit, whether so small a tax might not at least be altogether appropriated for the payment of public officers, whose duties it would be to protect the public in the purchase of drugs against their own ignorance, and the avarice of the evil-disposed druggist. All these matters it will be the duty of the Committee to inquire into.

Again, upon the subject of Chemical Pharmacy, it will be the duty of the Committee to examine why it is that this most important branch has been so shamefully neglected in this country, whilst our scientific neighbours of France have been daily adding to the powers of the practitioner by their skilful chemical analysis.

Their late discoveries, recorded both in this Journal and other periodicals, are now familiar to the medical public, and make us blush, as Englishmen, that we have not a name in the healing art to be placed in competition with their distinguished pharmacutists. With us the name of "chemist" is a *nom de guerre*, and only means, in general, that the person who claims the adjunct carries on open war against, and acts in defiance of, the Apothecaries' Hall. Nor can the Apothecaries' Hall complain of this abuse, seeing that not a single member of its own body deserves the honourable title, or, at least, has proved his desert by his discoveries. In mathematical sciences we have had a Newton, whose transcendent fame, above that of all others, the student may conceive he has made some advance in knowledge, according as his power of appreciating it increases. In chemistry we have had a Davy;—we now boast of a Faraday, whose life is a comment on the innate love of science, the attribute of true genius. But, in that most valuable and practical art, of which the College of Physicians professes itself the censor, of which another corporation is the guardian, we cannot name a single successful English cultivator. When we consider how desirable it is that all pharmaceutical agents should be prepared by chemical agency,—that a medicine elaborated by chemical agency comes from the mint of nature, pure and unalloyed, the same yesterday, to-day, and for ever;—when we consider, to take an example, how precisely a physician can calculate upon the operation of so many grains of quinine, where ounces of bark might have baffled his utmost skill,—how iodine with unerring certainty operates where it were vain to have recourse to burnt sponge,—how—but it is unnecessary to add to the

list,—can there be a doubt that pharmaceutical chemistry is of the utmost value, and that it has been grossly neglected by those among us who pledge themselves to be its promoters?

We have but lightly touched upon these matters. There are other parts of the subject still to be investigated, which we have not even opened. As we have already requested some of our friends not to deem the Committee undiscerning in that it had not yet investigated the most important portion of the subject of medical reform; in the same spirit we beg liberty to be allowed to continue our comments upon these subjects, without, for the present, incurring the censure of having overlooked more important topics.

Reviews.

The Dublin Journal of Medical and Chemical Science, including the latest discoveries in Medicine, Surgery, Chemistry, and the Collateral Sciences. No. XIV., Vol. V. May. Hodges and Smith.

(Concluded from page 510.)

THE second case was one of disease of the hip joint, or the Morbus Coxarius of former writers, which continued for months, attended by the most acute suffering, and for which leeches, cupping, the actual cautery, and moxas, were the remedies, as we have repeatedly witnessed in our own and foreign hospitals.

"CASE V.—On the 28th of Nov. 1833, I was requested to see Miss Eliza O——, residing at Booterstown Avenue, near this city, aged 14, of an active, lively disposition, with blue eyes, and a clear delicate complexion. This young lady's mother informed me, that her daughter was observed, about a month ago, to limp about the house, apparently without pain; that in walking she moved the right leg outwards, and so as to describe a half-circle; that about a fortnight ago she complained of a pain in the left hip, groin, and knee, which was at first of a dull kind, but gradually became so acute, particularly at night, that her father became alarmed, and confined her to

bed. On carefully placing her for examination in the horizontal position, the internal malleolus of the left leg is situated lower by half an inch than that of the right; and the left heel evidently descends lower than the right. Striking the left heel, ever so gently, gives her great pain in the hip joint. The slightest pressure over the left groin, where there is some tumefaction, or on the corresponding trochanter, also causes severe pain in the hip joint. She complains of acute pain in the knee, shooting along the leg to the ankle; and she cannot bear the left ham to be pressed upon. Pressure along the course of the sciatic nerve produces no inconvenience. When taken out of bed, she stands with the affected knee bent and advanced beyond the sound one; and puts only the toes of the left foot to the ground; the left nates is flattened, flaccid, and apparently broader than the right, and there is no vestige of the transverse fold in which it naturally terminates. Pulse natural, general health little impaired, bowels rather confined, tongue whitish.

"This being the first opportunity that I had of treating the disease in the hip, on the mercurial plan, I was naturally anxious to give it a trial. But I considered it only fair and prudent to represent all the facts of the case to the young lady's parents, and recommend a consultation. My representation had the desired effect, and it was agreed to call in the able assistance of my colleague, Mr. R. Carmichael. Six leeches, followed by cold lotions, were ordered to be applied to the affected groin.

"On the following morning she was seen, in consultation with me, by Mr. Carmichael, who at once recognised the case as one of hip disease, and concurred in the propriety of employing mercury, in conjunction with other means. Ordered to take a pill consisting of one grain of calomel and two grains of aromatic powder three times daily, until the mouth becomes touched; to have a blister applied behind the left great trochanter; and the vesicated surface to be dressed with tartar emetic ointment; also, to be confined to the horizontal position in bed, and to lie on a firm mattress.

"Dec. 3rd.—Mouth slightly affected. Says that she feels greatly relieved from pain, but complains of the severity of the blisters;

bowels still confined. Pills to be repeated until the mouth becomes more decidedly affected; and if the bowels be not moved before to-morrow morning to have a dose of castor oil.

"5th.—Has taken five pills since last visit. Took also a dose of castor oil yesterday morning, which produced dark green discharges from the bowels. The gums are now tender, and the breath is foetid. There is no pain on pressure upon the groin, or in the ham, of the affected side. She no longer complains of pains in the knee or leg; the left nates is nearly as plump and firm as the right, and the transverse folds at its lower margin has reappeared, and is distinctly marked, but it is situated somewhat lower down than on the opposite side; and both lower limbs are precisely of the same length. Pills omitted; allowed weak chicken broth.

"8th.—No pain whatever in the groin, knee, or ham. On being placed standing on the floor, she brings both heels together, and walks without feeling the least inconvenience; scarcely any ptyalism. Ordered two grains of calomel every day, and to go on, in other respects, as before.

"9th.—Seen by Mr. Carmichael and myself; admitted to have little, if any, vestige of the disease. Mouth slightly affected; bowels regular. Says that she feels rather weak, yet in the absence of her attendant, has been detected in running about the room, as if she had no complaint. Ordered to have strong beef tea and chicken broth *ad libitum*; to take two grains of calomel every second day, and every vigilance to be used in keeping her confined to bed, and in the horizontal position.

"17th.—Scarcely any affection of the mouth. Health in every respect good, and feels much stronger; none of the external signs of the disease visible; and, on being permitted, walks about the room without feeling the least pain, or any greater weakness in the left than in the right limb. Calomel discontinued. Permitted to have moderate quantities of solid animal food, and light table beer, but still to be confined to the recumbent position.

"30th.—Seen by Mr. Carmichael and myself. In excellent health; insists that she is 'as strong and well as ever,' and is very urgent to be allowed to get up and walk about; and, after the most careful examination, no

difference whatever is observable in the lower extremities. Directed to be confined to a sofa; to have a little wine and water, and the most nourishing articles of food; and to take half a pint of the compound infusion of sarsaparilla daily, for some weeks.

"After being treated thus for three weeks, this young lady was at length permitted to walk about, and return to her former pursuits. Since that time, she has had no enlargement of the lymphatic glands, nor any of the other unpleasant consequences of the use of mercury in strumous persons; and she is now, (March the 1st, 1834,) in perfect health."

The following letter and case are from one of the most distinguished members of the profession in this country, and will, no doubt, be read with that interest and attention which any communication from him is sure to excite.

" Rutland-square, Feb. 20th, 1834.

"MY DEAR SIR,—Agreeable to your wishes I send you a brief account of the case of hip joint disease, in which the mercurial plan of treatment was attended with the most decided advantage, as it seemed to check at once the progress of the disease; an effect which is no doubt owing to the powers which the exhibition of this mineral possesses in stopping the progress of membranous inflammation. That the synovial membrane of the hip joint, and not the cartilage, is often primarily engaged in this disease, we may infer from one of the first symptoms which marks its commencement,—a fulness of the groin, depending in all probability upon the increased secretion into the joint, similar to that which we know takes place in synovitis of the knee. You will observe, that as soon as the inflammatory symptoms had yielded to this treatment, the further exhibition of mercury was discontinued, and absolute rest, with counter-stimulants, and the exhibition of sarsaparilla, only enjoined.

"Believe me, yours truly,

"RICHARD CARMICHAEL."

"CASE VI.—On the 21st of last December, I was called to the King's County to see a young gentleman about twelve years of age, whom I found, on examination, to labour under all the symptoms of an acute attack of

the first stage of morbus coxarum. There were fulness of the groin, flatness of the nates of the side affected, pain in the knee; and when the heel was struck, it gave the most acute pain in the joint of the hip. The patient could not be moved without occasioning great distress. When placed in the erect position, he rested on the toes of the affected limb advanced beyond the other, and there was an apparent lengthening of the former. Pulse rapid, great thirst, and other symptoms of high symptomatic fever were present. This boy had, I understood, a bilious fever for some time, and that the attack above described immediately followed.

"The frequent application of leeches to the groin and hip was recommended, afterwards blisters, followed by dressings of tartar emetic ointment applied for half an hour daily. Mercury was ordered in small doses, so as to affect the gums, but not to an extent to produce salivation, as the boy had been greatly exhausted by previous pain and symptomatic fever. I did not see him again, as I immediately returned to Dublin, but had the following communication from Dr. Fry, of Forbane. He writes, on the 12th of January, 'I have much pleasure in informing you, that our patient has been progressively advancing towards recovery since I last communicated with you on the subject. The mercurial action, though not to the extent of salivation, has been, with very little intermission, exerted the whole time. Digestion goes on well, which appears by his bowels acting naturally, once every day, and sometimes twice. Appetite very good. There is now no difference in the length of both legs, and motion in the affected one can be borne without apparent pain, as formerly. We have, however, adhered to your wish in enjoining the most perfect quietness.'

"In my reply, I recommended that the mercury should now be discontinued, that an infusion of sarsaparilla in lime water should be exhibited in such quantities as the stomach would bear without inconvenience; and that the discharge from the blistered surfaces, on the groin and behind the trochanter, should be promoted, by dressing them occasionally with tartar emetic ointment for half an hour.

"On the 2nd of February, Dr. Fry again writes, 'I have much pleasure in informing

you, that Master ——— has been steadily advancing towards recovery since my last. The sarsaparilla with lime water appearing to agree remarkably well with him. His general health seems quite recovered, and all inflammatory appearances in the local affection have entirely subsided. He has occupied his new bed (Earl's) for some time. It seems admirably constructed for persons so affected, and, in his particular case, has contributed much to his general comfort.' Accompanying this statement, the father of the boy adds in a postscript, 'my little fellow thinks himself so well now, that he says he could walk if he was allowed; but, of course, this is not to be thought of as yet.'

"The following case is communicated by my friend, Mr. Cusack Roney, one of the senior surgeons of the Meath Hospital, a gentleman of very considerable experience, and who has put the practice to the severest possible test, by employing no external applications whatever, and trusting solely to the internal exhibition of mercury.

"CASE VII.—John Rice, a tanner by trade, aged 17, robust, and of a scrofulous constitution, having light-blue eyes, fair complexion, and thick lips, admitted on the 27th of November, 1833, into the Meath Hospital. The surgeon, who admitted him, directed scarification and cupping behind the trochanter of the left femur. On the 1st of December following, he was placed under my care, and the appearances noted were these: apparent elongation of the left lower extremity; flattening, flaccidity, and unusual breadth of the nates of the same side; no vestige of the fold formed by the nates of this side; and when standing, the knee was flexed, he stood on his toes, and with the affected limb considerably advanced beyond the sound one. He complained of severe pain in the knee and at the groin, but there was no swelling in either of these situations. When the heel was struck, he experienced acute pain in the hip-joint, and he felt the same sensation when he attempted to stand, or bear, upon the affected limb. He said also, that he was frequently awoken at night by pains, which were much more severe than those which he felt during the day. On questioning him as to these pains, he stated, that they were at first of a dull kind, and had gradually increased in

intensity. His general health appeared to be little, if at all, injured.

"Dec. 3rd. No improvement. Twelve leeches to be applied to the hip.

"6th. Still no improvement. Tartar emetic ointment to be freely applied over the whole of the affected hip.

"8th. General pustulation of the hip. Still no change for the better in the local symptoms.

"12th. Pustules nearly gone, but no apparent change. Tartar emetic ointment repeated.

"14th. No other sensible change in the local symptoms, further than feeling at ease when he does not move in bed. Seen and examined by Dr. O'Beirne, who recommended the active use of mercury, and so as to affect the mouth as quickly as possible. A scruple of calomel directed to be made into ten pills, and one of these to be taken thrice daily.

"17th. Mouth very slightly affected. Feels somewhat easier. Calomel pills repeated.

"19th. A considerable degree of salivation; slept soundly last night; both inferior extremities are of the same length; he has no pain in either the knee or the groin; the nates of the affected side is more plump; and, contrary to the strict injunctions given to him, he has been walking about the ward, and, apparently, as if he had no complaint of the kind.

"20th. Has persevered in walking about the ward, and he now declares, that he is perfectly well, and insists upon being allowed to go home. Discharged; and walked away without the least limping, or appearing to feel any pain whatever.

"About the latter end of last February, this man again presented himself at the Meath Hospital, with all the symptoms of hip disease, in its first stage. He was admitted by one of the surgeons, who ordered moxa to be applied behind the great trochanter of the affected side. But he again proved refractory, refused to permit the application of the moxa, and left the hospital without waiting to be discharged."

Dr. O'Beirne quotes some foreign clinical reports on the efficacy of mercurial frictions, in rheumatic affections of the joints, more particularly those of M.M. Trousseau and Recamier. He also refers to the practice of Drs. Ebel and Wedekind described in the January number of our Dublin contemporary, of employing corrosive sublimate in rheumatic

affections of the joints, but it was not tried on scrofulous subjects, or in ulceration of the cartilages.

Dr. O'Beirne very strongly recommends an infusion of sarsaparilla in lime water, in preference to all officinal preparations of this remedy. He has found it most effectual in syphilitic and mercurial affections, after all other preparations had failed. He has likewise found the infusion of great benefit in catarrh of the bladder. The following is the formula:—

“*R. Radicis sarsaparillæ Jamaicensis
concissæ uncias quatuor.*

Radici glycyrrhizæ semunciam.

Aquæ calcis libras duas.

Macera per horas viginti quatuor in vase vitreo optimè operculato, et in loco frigido et obscuro; dein cola in usum.

Sumat hujusce infusi dimidium, partitis vicibus, quotidie.

“This formula differs from that of the Dublin Pharmacopœia, first, in containing double the quantity of sarsaparilla; secondly, in containing liquorice root; thirdly, in requiring the infusion to proceed for twenty-four instead of twelve hours; fourthly, in not requiring agitation of the contents of the vessel. This formula also differs from that given by Dr. Copland, first, in containing double the quantity of sarsaparilla; secondly, in not requiring the sarsaparilla to be bruised; thirdly, in not requiring the agitation of the contents of the vessel; fourthly, in requiring the glass vessel to be very well, instead of slightly stopped.”

The second article is headed, A Case of Pneumo-thorax, from Perforation at the posterior surface of the Lung. By Mr. Poole, assistant-surgeon to the 32nd regiment. The narrator is entitled to credit for his accurate diagnosis.

The third article is a Surgical Report of the Cases treated in the Meath Hospital during the past year. By W. H. Porter, Lecturer on Anatomy and Surgery. The following are the principal cases:—1. Aneurism occasioned by the sequestrum, in a case of necrosis of the tibia. 2. Functional derangement of the brain, the result of injury, cured by the operation of the trepan. 3. Curious and interesting case of bronchotomy. 4. Disease of the lymphatics of the left arm, amputation at the shoulder-joint. These cases are deeply interesting to the practical surgeon, and therefore

we shall notice them fully on another occasion. We wish our London hospital surgeons would imitate the example set them by their brethren in Edinburgh and Dublin, and not allow the immense field of practical surgery in their possession to run wild and remain uncultivated.

The fourth article is entitled, a Case of Trial for Poisoning by Arsenic. By T. E. Beatty, M.D., M.R.I.A., Professor of Medical Jurisprudence to the Royal College of Surgeons in Ireland. This was a most difficult case to decide, as the deceased had taken laudanum and arsenic. The evidence on which the accused persons were convicted was entirely circumstantial. Dr. Beatty obtained arsenic by the usual process, and a druggist's apprentice swore that one of the prisoners had purchased that poison, to which he had added oil of aniseeds, and also a quantity of laudanum. The narrator alludes to the shortness of time (five hours) in which death took place, and after adducing ample proof of analogous cases from the work of Dr. Christison, he concludes by citing a case published by Mr. Wright of Dublin, in the *Lancet*, vol. xvi., p. 612, in which death took place in four hours from the time the poison had been swallowed.

The succeeding paper is furnished by Dr. S. Cusack, on Nervous Diseases occurring principally in women. The author describes those nervous or neuralgic pains in the side so common to dyspeptic, hypochondriacal, and nervous women, which, according to others, often depend on spinal irritation, or derangement of menstruation. He points out the inefficacy of depletion and counter-irritation over the affected part; and the beneficial results produced by alterative doses of blue pill, galbanum, followed by aperients. His usual mode of administering these medicines is the following:—*R. Pil. galb. c., gr. vij., pil. hydrag., gr. iij., fiat pil. ij., 3a quaque nocte sumendæ. R. Inf. quassie, 3xij., mag. sulph, 3iss., fiat hanstus 3a mane sumendus.*

We highly approve of this mode of treatment, but we must state that it has not been so successful in our practice, as Dr. Cusack informs us it has been in his. We have often found it necessary in the disorders under notice, to examine the spine, and very frequently have discovered that some vertebra was pained on pressure, and then leeching and antimonial

ointment became necessary. In many patients too, there is more or less spinal distortion, and unless this is remedied by the mechanical contrivances, or "supports," such as those of Mrs. Hart, late Mrs. Callam, so strongly recommended by Sir A. Cooper, Mr. Brodie, and other eminent surgeons in London, very little good will be done by internal medicine, and at best only a temporary relief afforded*. We have also observed the most remarkable alleviation produced by the addition of one-grain of strychnine to the above pills. We are ready to admit that Dr. Cusack's plan is often effectual, when the spine is natural; but it certainly fails in the class of cases to which we have alluded.

The fifth original communication is on *Pathological Researches*, by Dr. Morgan, of the Whitworth Hospital. He details two instructive cases of disease in the brain, unaccompanied by severe pain or symptoms of acute inflammatory action. In one, the petrous portion of the temporal bone was diseased, and the primary attack was attributed to imprudent exposure to cold by bathing in the sea, soon after the employment of mercury for the removal of syphilis.

The sixth and last article is headed—*Cases of Uterine Hæmorrhage*. By Dr. Churchill, Physician to the Wellesley Lying-In Dispensary. The first case was one of placental presentation, delivery was delayed, and death ensued. Dr. Churchill candidly avowed, after mature reflection on the result, that early delivery was a better mode of practice. In the second case delivery was performed while "the pulse was absent at the wrist, the heart's action feeble and fluttering, and the surface cold." No hæmorrhage occurred after delivery. The edge of the placenta presented at the os uteri, so that complete dilatation was effected without disturbing the placenta itself. The patient was ordered fifteen drops of laudanum in some cinnamon-water every hour, and took 180 drops during the night.

* Mrs. Hart's various machines for spinal distortion and deformities of the limbs, were proposed by the most eminent physicians and surgeons in London, and are of the greatest service in those nervous and hysterical complaints which are little benefited by remedies. These may be had at Great Queen-street, Lincoln's-Inn-Fields.

This practice was proposed by us some years since, and is followed by our experienced and celebrated friend, Mr. Barlow, of Blackburn. He assured us, last summer, that he never lost a patient by adopting it. The old plan of allowing the woman to sink, for fear of injuring the os uteri by "forcing it," or rather dilating it, will soon be abandoned. Every obstetrician must admit that the os uteri is capable of dilatation at any period of pregnancy, and more especially in the latter months, when placental hæmorrhage is most common; and great force or rudeness should be practised to rupture the uterine orifice. We lately delivered a lady, under the circumstances mentioned above, at the request of Mr. Austin, of Clerkenwell, but first exhibited brandy and double doses of *secale cornutum*, so as to increase uterine action, after it was excited by the introduction of the hand. Our object was accomplished; the uterus contracted after the extraction of the foetus, the placenta was expelled, and there was no hæmorrhage. The patient was so exhausted previously to the operation, that we had placed the transfusing instruments on a table. We mention this case to show the feasibility of delivery, and the value of *secale cornutum* before the operation is resorted to. The powers of life were so low, that full doses were necessary. The essence of the remedy, as prepared by Mr. Bass, of Hatton-Garden, was used on this occasion, and enables the practitioner to administer an efficacious remedy with as little delay as possible.

The last article of value in our esteemed contemporary is from the pen of Professor Graves, and entitled,—*Notices of Modern German Works and Periodicals*. The learned Professor gives a brief account of all the German periodicals, which want of space compels us to omit.

Comparing the journal before us with its contemporaries, we unhesitatingly pronounce it one of the best extant in this country.

An Introduction to the Study and Practice of Medicine, comprising a brief Exposition of the various branches of Medical Knowledge; Directions for their Study; References to the best Elementary and Practical Books; and a Selection of Medical Precepts. By JOHN DOWSON, M. D.,

Member of the Royal College of Surgeons in London, and of the Royal Medical Society of Edinburgh. London: Longman and Co. 1834.

THIS is a sensible little manual of advice to the student, but we consider its list of medical works to be very defective. We extract the following remarks upon the errors most frequently committed by students in hospital attendance, which strike us as extremely judicious and pertinent:—

“The most important of these errors is their inclination to see many cases superficially rather than few cases well. They are determined to see every thing, and for that very reason they see nothing as they ought. A very little consideration might satisfy them that more is learnt by accurately observing one case, from its commencement to its termination, than by glancing at a thousand. Closely connected with the error just pointed out, is that of selecting the largest hospitals for attendance, instead of those in which clinical instruction is given with the greatest ability, regularity, and frequency.

“Another very prevalent error is the eagerness with which students run to see rare cases and capital operations, for which they often neglect the opportunity of gaining much more useful information. For the sake of seeing an enormous tumour, such as they may never be called upon to treat; or of catching a glimpse of a sanguinary operation, which they may never have to perform; students continually neglect the regular prosecution of their dissections, break the connexion of their lectures and demonstrations, interrupt the course of their ordinary hospital attendance, and thus lose much knowledge which they might have obtained, respecting far more important, because far more common, cases. To watch with care the progress of common diseases, and to learn and fix in the memory the most successful mode of treating them, under the various modifications produced by age, sex, constitution, and mode of life, are the most important objects to every student.

“To know
That which before us lies in daily life,
Is the prime wisdom; what is more, is fume,
Or emptiness, or fond impertinence,
And renders us in things that most concern
Unpractic'd, unprepar'd, and still to seek:
“MILTON.”

Foreign Hospital Reports.

HÔTEL DIEU.

Gun-shot Wound.

A FEMALE cook, 26 years of age, of nervous temperament, was admitted into this hospital for a gun-shot wound of the thigh, which happened to her during the last disturbances at Paris. Whilst in a house in the Rue Transnonain on the morning of the 14th of April, some soldiers entered, killed four men who were in the same room, and wounded also two women and a child. This patient, endeavouring to save the life of one of her relations, threw herself on her knees before the soldiers, and received the bullet in the inferior and internal part of the thigh. The ball appears to have been repelled by the femur, as it was found in her clothes. M. Dupuytren enlarged the wound, and extracted portions of clothing. The femoral artery was not wounded. Simple dressings were applied, and the patient is now doing well.

Violent Contusion of the Face—Necrosis of the Os Malum—Fistula—Treatment.

A young man, 23 years of age, of a sanguineo-lymphatic temperament, was admitted on the 21st of April, under the care of M. Dupuytren. He had suffered for several years from pain in the chest, accompanied with a pricking sensation; had several times expectorated sanguineous sputa; his cheeks were flushed; and other symptoms threatened pulmonary consumption. This was not, however, the complaint for which he was admitted. Three months previous he had received a violent blow on the left cheek, which was followed by much tumefaction of an inflammatory nature; an abscess formed, which, when opened, discharged a quantity of purulent matter. After this he got better, but a fistula remained, on a level with the articulation of the malar and superior maxillary bones, for the cure of which he came under the care of M. Dupuytren. On examination with the probe, necrosis of the greater part of the anterior surface of the malar bone was detected. The fistulous opening was enlarged, and small portions of dead bone extracted. The wound was then dressed, its edges kept a little separated to allow of the free exit of the other

portions of carious bone. There being still a large portion not sufficiently loosened, M. Dupuytren has had an instrument constructed, in shape like a gimblet, with which he intends to perforate and extract the dead bone. Since the first operation the patient has had no untoward symptoms; and, to check any determination to the chest, an issue has been applied to the arm.

A Woman delivered of Four Infants without the Assistance of a Midwife.

Six weeks ago, a woman in the Commune de Begney was confined with four living children. This event, not of rare occurrence in Egypt, according to Pliny, is far from being common in Europe. There was no medical attendant, consequently we are unable to gain on this point any useful information. Three of the infants lived only a few hours after birth, the fourth is not expected to survive long.

Enormous Dilatation of the Stomach—Vomiting for thirty years—Hypertrophy of the Muscular Tunic.

The woman Troussel, 50 years of age, was admitted the 19th of April, under the care of M. Piorry. At the age of twenty she was seized, after a favourable parturition, with severe pains extending from the umbilicus to the spine; this lasted for seventeen months, and was followed by vomiting, and severe pain in the epigastric region, which has not since left her. She has been subject to complications of her disorder whenever she has taken any food which disagreed with her. On examination by percussion in the recumbent position, a dulness of sound is perceptible on the left side of the abdomen. The situation of this dulness changes, when the patient is moved; the stomach, which is evidently much dilated, seems to occupy one half of the abdominal cavity; there is perfect sonorousness below it. The patient says she can sometimes feel in the region of the stomach a ball which she can displace by pressure with the hand; [stomach in a contracted state;] vomits at will. Some milk, and a little food were allowed, and she was recommended to promote the ejection of matters contained in her stomach. In the evening she vomited spontaneously three or four pints of clear fluid, containing food in an almost digested state, by which she was re-

lieved. The next day the stomach on examination was found less; the other symptoms remained the same.

M. Piorry, believing his diagnosis confirmed by the bearing of the case, states that it is a very uncommon occurrence to find organic lesion take place so early, and still more so to continue for thirty years. He thinks it very probable, notwithstanding the absence of black vomiting, and of discoloration of the skin, that the disease is caused by scirrhus of the pylorus; but as the general health of the patient has only suffered through want of due alimentation, the emaciation being the result only of protracted suffering, more particularly as the symptoms appear to have diminished during the last three years, he believes the patient may yet live for some time, providing she follows the advice given her, and refrains from all improper nourishment.

HÔPITAL DE LA PITIE.

Encephaloid Cancer of the Stomach unattended with Vomiting—Death—Autopsy.

BOUCHER, a washerwoman, ætat. 60, was seized, in June, 1833, with general uneasiness; her skin became yellow, and her appetite voracious; diarrhoea came on, lasted two weeks, and then disappeared. Since this time the patient has suffered at intervals from violent colic, but she has never had any vomiting. On the 16th January, 1834, she was admitted into the hospital in a very emaciated condition; skin of a yellowish hue. On examination, a rounded tumour of considerable hardness, of the size of the fist, could be felt in the left hypochondrium, there was also pulsation to be distinguished in the epigastrium; tongue was clean; no thirst, nausea, or vomiting; but slight diarrhoea; has had some difficulty of respiration after exercise for the last ten years, which lately has much increased; no palpitation of the heart; has had anasarca in the left leg; pulse 80, regular. M. Rostan supposes a cancerous tumour, first arising in the spleen, and thence gaining the cellular tissue and parietes of the intestine. A mucilaginous drink was prescribed: also mucilaginous and opiate injections.

On the 20th mercurial frictions over the tumour.

28th. Slight infiltration of the lower limbs; tumour had augmented and become painful to the touch. To the above treatment was added the exhibition of four grains of the hydriodate of potass in a five ounce mixture.

Feb. 3rd. Has had for the last two days severe colic. The tumour seems to be composed of two lobes, one occupying the right side, and the other the umbilical region; stools containing blackish matter.

5th. Blister to the tumour. Cough frequent; respiration more difficult; hands become cedematous. Thus she continued till the 17th.

From this time to the 21st she got gradually worse; there was excessive prostration; coldness of the skin; and death soon terminated her sufferings.

Autopsy.—On examination, an encephaloid cancer was found to occupy the pyloric extremity and right half of the stomach. The tumour caused compression of the vena cava inferior. The inferior lobe of the left lung was affected with gangrenous ulceration.

HÔPITAL SALPETRIERE.

Excision of the Ungual Portion of the Thumb
—Re-application of the separated Part half an Hour after its separation—Union
—Cicatrised—and Cure.

One of the female servants of this hospital, whilst cutting bread with a fixed knife for that purpose for the patients, completely severed the greater portion of the last phalang of the thumb from the left hand. The medical attendant saw her half an hour afterwards, and found that division had taken place at the root of the nail. The separated portion, which had been picked up from the ground, was pale, bloodless, and cold; it was, however, washed, and reapplied with plasters and bandages. Twenty days afterwards the parts had cicatrised, and the extremity of the thumb was quite sensitive.

LITERARY INTELLIGENCE.

In the Press—An Inquiry into the Nature of Sleep and Death, with a View to ascertain the more immediate Causes of Death, and the better Regulation of the Means of obviating them, being the concluding part of the Experimental Inquiry into the Laws of the Vital Functions. By A. P. W. Philip, M.D., F.R.S.

BOOKS.

A Series of Anatomical Plates in Lithography, with References and Physiological Comments, illustrating the Structures of the Different Parts of the Human Body. Edited by JONES QUAIN, M.D., Professor of Anatomy in the University of London. Fasciculus XII. Taylor.

The Principles and Practice of Obstetric Medicine, in a Series of Systematic Dissertations on Midwifery, and on the Diseases of Women and Children. Illustrated by numerous Plates. By DAVID D. DAVIS, M.D., Professor of Midwifery in the University of London. Part XXXI. Taylor.

Principles of Physiological Medicine, in the form of Propositions, embracing Physiology, Pathology, and Therapeutics, with Commentaries relating to Pathology. By F. J. V. BROUSSAIS, M. D., &c. &c. Translated from the French by ISAAC HAYS, M.D., and R. EOLSFELD GRIFFITH, M.D. Philadelphia, 1832. Carey and Lea.

CORRESPONDENTS.

Mr. Turner.—We have turned it to account.
Mr. Atkinson.—The observations are just, but are too well known to excite any interest.
Mr. Lee.—The communication is under consideration.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE XCI., DELIVERED APRIL 19, 1833.

GENTLEMEN,—*Malignant diseases of the eye.* It is scarcely necessary for me to remind you, that the eye is subject to three malignant diseases, namely, *cancer*, *melanosis* and *fungus hæmatodes*.

Cancer frequently begins in the conjunctiva, whence it afterwards extends to the eyelids, *caruncula lachrymalis*, and the eye itself. The lachrymal gland is found not to be so often implicated, as was once to be supposed; though most operators remove it with the rest of the contents of the orbit, when they extirpate the eye for this disease.

As cancer commences on the external parts of the eye, and, therefore, in its early stage, may admit of effectual removal, it is a less formidable disease than *fungus hæmatodes*, which first attacks the optic nerve and retina, the pupil becoming dilated, of a dark amber, or greenish hue, the iris motionless, and the sight seriously impaired or destroyed from the very first. In an early stage of the disease, a white shining substance, compared to burnished iron, may be seen through the pupil at the back part of the eye. As the disease advances, this substance is found gradually to extend more and more forwards, and to be of a solid nature. It is indeed a medullary mass, occupying the whole interior of the eye behind the iris, and presenting an amber or brown appearance.

Next, the form of the eyeball begins to deviate from what is natural; the sclerotica becomes of a dark blue or livid colour; and the fungus gets into the anterior chamber. Lastly, the cornea or the sclerotica ulcerates, so that in the former event the fungus protrudes; and in the latter it forms a tumour covered by the conjunctiva.

It is generally rapid in its growth, often

attains a considerable size, is of a dark red or purple colour, and is frequently attended with hæmorrhage and sloughing of its most prominent part; the absorbent glands about the parotid and under the jaw being also affected. The disease, as I have said, begins in the optic nerve and retina, and corresponds in its ungovernable and fatal nature to *fungus hæmatodes*, or medullary sarcoma in other situations. It is a disease very much restricted to children.

With few exceptions the operation of extirpating the eye for this disease has been of no avail.

With respect to melanosis, or the deposition into the eye of a peculiar black substance, attended with total disorganisation of it, if it be confined to the eyeball, and not extended to the optic nerve, the eye may be removed with a greater prospect of success, than when it is the seat of *fungus hæmatodes*.

The manner of removing the eye for malignant disease, I will show on the dead subject in the morning lectures on the operations.

Diseases of the ear. What is called *ear ache* frequently proceeds from inflammation of the *meatus auditorius*, or the *tympanum* itself, the pain being in general severe; a circumstance observed to attend inflammation of all textures, whose nature and situation prevent them from readily yielding to the swelling, commonly the result of that affection. Inflammation within the ear may proceed to suppuration, the abscess make its way out through the *meatus auditorius externus*, the *Eustachian tube*, or the *membrana tympani*, or even behind the ear, with or without having pervaded the cells of the mastoid process, and occasioned caries of the bone. According to my experience, the worst suppurations of the ear occur in scrofulous children, in whom they are frequently accompanied by disease of the bony parts of the organ, followed in some instances by the necrosis and separation of the ossicula. But, gentlemen, inflammation and suppuration within the ear may not only cause these consequences, and more or less complete deafness, but extend their effects to the *dura mater*, and

destroy the patient. One preparation illustrating this fact we had upon the table on a former evening.

The *treatment* of acute inflammation of the ear ought to be rigorously antiphlogistic. In adults, copious venesection should be resorted to, and in children, leeches. Besides these means, fomentations and purgatives, followed by blisters, are also requisite.

* When exfoliations occur, they most commonly consist of the meatus externus, or of the outer laminae of the mastoid process.

If, after the reduction of the inflammation, the discharge of matter should continue, and the patient appear to be scrofulous, alterative medicines, as iodine internally and iodine lotions, should be employed; or you may employ an injection of a weak solution of the nitrate of silver. If there be diseased bone present, of course the discharge will not cease till exfoliation is completed.

The *meatus auditorius* is frequently blocked up, and the external side of the membrana tympani covered with hard, dry masses of cerumen, so as to render the patient entirely deaf. Such hardened pellets of wax, if neglected, may ultimately cause a great deal of irritation, followed by inflammation and ulceration of the membrana tympani and lining of the passage, and they always give rise to a sensation of false confused sounds in the ear, which are truly distressing to the patient.

The cure consists in washing out the meatus auditorius by means of a syringe, capable of holding at least four or six ounces of warm water. This should be thrown into the passage, so as to make it regurgitate with considerable rapidity. You will generally have to do this several times, before the pellets are loose enough to be washed out.

The meatus auditorius is occasionally the seat of polypi and other excrescences. When situated near the orifice they may be taken hold of with a hook, and cut away; but, in other cases, it is best to extract them with forceps, and apply the nitrate of silver, or tinctura ferri muriatis to the part to which they were attached.

Extraneous Substances in the Meatus Auditorius Externus.—When insects get into the ear, the best plan is to take them out at once with a pair of forceps if they can be seen. If not, you employ a piece of lint, dipped in honey or oil, and put on the end of a probe; these, on account of their adhesiveness, will entangle any small insect, and bring it out. Then the passage is to be washed out with a syringe. This last plan I find the best of all, not only for insects, but for the removal of peas, small pebbles, &c. The regurgitation quickly brings them out, when all other means fail. One day, when I was visiting the Fleet Prison Infirmary, a child was brought to me with a pebble in each of its ears, that had been there a twelvemonth, and had now excited violent pain and inflammation, attended with total deafness. Various

surgeons had failed in their attempts to get these foreign bodies out. I immediately tried what could be done with a large syringe, and had the satisfaction of soon bringing the pebbles so near the external orifice, that they admitted of being hooked out with a bent probe.

Almond or sweet oil, dropped into the ear, soon destroys any insect lodged in it.

Deafness from more internal causes than those which I have specified, forms too long and complicated a subject for consideration in a course of lectures on surgery in general. It may arise from obstruction of the Eustachian tube by mucus, as happens in severe catarrh, by the pressure of a tumour, as is sometimes exemplified in cases of polypi, or swelled tonsils, or in the effects of syphilitic ulceration or sloughing sore throats.

For the removal of deafness, caused by permanent obstruction of the Eustachian tube, Sir Astley Cooper suggested the practice of making a small puncture in the anterior and inferior part of the membrana tympani, a method that has been attended with a degree of success, but which should not be done without mature consideration, and a proper discrimination of the cases to which alone it is applicable.

Diseases of the Labyrinth, or of the complicated apparatus composing the internal ear, are the cases which, generally speaking, completely baffle the art and science of surgery. You scarcely ever have any clue to their cause, or even to the precise parts affected, so that no surprise ought to be entertained at the little success with which such kinds of deafness are treated.

Amongst the varieties of disease to which the labyrinth is liable, I may mention—

1. Disease of the fenestra ovalis and fenestra rotunda, as ulceration and thickening.
2. Malformation of these apertures.
3. Inflammation of the nervous membrane lining the labyrinth.
4. Malformation of the labyrinth.
5. Alteration or deficiency of the liquor of Cotunni.
6. Affections of the nerve of hearing, analogous to amaurotic diseases of the eye.

Gentlemen, you know that when one eye becomes diseased, the other is much disposed to fall into the same condition; but a similar fact does not prevail with respect to the ears. Numerous persons are more or less deaf on one side, but the other ear usually continues its functions very well, and even as long as if the other ear had no defect.

Every kind of deafness from malformation of the labyrinth must be set down as incurable.

Nervous deafness should be treated, I think, on principles analogous to those adopted for the cure of amaurosis. Inveterate cases of long standing must, of course, be hopeless.

Diseases about the Face.—*Lupus*, or *noli me tangere*, is a tubercular disease, attacking the skin of the face, and very frequently that

of the nose. It begins with inflammation, followed by the formation of bright red tubercles of the skin, which change into superficial, but ill-conditioned, foul ulcerations, spreading with a red margin, and gradually destroying the affected parts of the skin. The disease, indeed, sometimes extends more deeply, as you find exemplified on the nose, where it often destroys the alæ, and all the cartilaginous part of that organ.

The form of lupus, attended with a bright red tuberculated appearance of the skin, is frequently considered to be scrofulous, for it is often accompanied by other marks of scrofula, and is noticed in young subjects. In adults, lupus is often joined with general derangement of the health, from intemperance or other causes. Bleeding, purgatives and low diet, are sometimes required, before other means will prove effective. The best applications, I think, are nitrate of silver or sulphate of copper in solution—lint being dipped in them, put on the part, and then covered with a pledget. The liquor arsenicalis, diluted, is also another favourite application. Arsenical pastes are also sometimes employed; but, on account of the fatal consequences which may arise from the free use of arsenic externally, I would advise you to be very cautious in applying these stronger preparations, especially as I believe lupus will always be as much benefited by other escharotics of equal strength, which have not the same deleterious qualities as arsenic. The diluted liquor arsenicalis, however, may be safely used; and so may the powder composed of ninety-five parts of calomel and five of oxide of arsenic, as used by Dupuytren. The ung. hydr. nitrat. and the ung. nitratis are likewise eligible dressings. I have known a lupus cured by excision.

Gentlemen, I will next make a few observations upon *Salivary Fistulae*. An opening in the cheek, from which the saliva escapes, and arising from a wound, ulceration, or phagedænic disease, involving the parotid gland, or duct, is called a *salivary fistula*. The duct has also been burst by violent blows. You will sometimes meet with cases in which the parotid duct becomes obstructed by a calculous formation within it, just in the same way as the salivary ducts under the tongue become occasionally blocked up with calculous matter. Calculi in the parotid duct, if not removed, may of course enlarge and excite inflammation and an abscess in the cheek. This bursts, and the flow of saliva from the opening immediately draws the surgeon's attention to the state of the parotid duct; a probe is introduced, and the calculus felt. Here it is hardly necessary for me to inform you, that the first indication is to extract the extraneous substance, and then endeavour to heal the ulcerated opening in the cheek.

If the parotid duct is recently wounded, the sides of the wound should be brought together, and pressure applied. Thus a salivary fistula may often be prevented altogether: either the

divided ends of the duct re-uniting, and the saliva resuming its original course, or, what is more probable, the wound in the face healing at every part, with the exception of a small fistulous track, which serves as a continuation of the duct into the cavity of the mouth. This is supposing the wound to have extended quite through the cheek.

When a salivary fistula is already formed, you may cure it by passing a seton from the fistulous opening into the mouth, keeping it in a certain time, and, after withdrawing it, applying the nitrate of silver to heal the outer opening. According to Professor Gibson, the use of the caustic alone will frequently succeed. Another ingenious plan is, what was adopted by Béclard, who passed a leaden style into the orifice of the portion of parotid duct connected with the gland, and then united the outer wound with the twisted suture. This is a quicker mode of cure than the seton, and more sure than simply closing a recent wound and applying pressure.

Gentlemen, I may now speak of *Diseases of the Antrum*; and first, of *abscesses* in it. The antrum, or rather its mucous lining, is subject to inflammation and suppuration. A darting pain is felt in the side of the face, usually supposed to be the tooth-ach, and, indeed, mostly connected with a carious state of the neighbouring teeth. If an abscess form, and the matter be prevented from passing into the nose by accidental obstruction, it may produce an expansion and attenuation of the sides of the antrum; and at length discharge itself either through the cheek, or, what is more common, into the mouth.

The indications are to procure a speedy outlet for the matter; to lessen inflammation and pain by antiphlogistic soothing means; to check the discharge and maintain cleanliness by the use of tepid, slightly astringent, injections; and, if there should be any dead bone, or carious teeth present, to remove them, as soon as circumstances will allow; the teeth as soon as the inflammation has somewhat abated, and the dead bone as soon as exfoliation is sufficiently advanced.

When there is a carious tooth below the antrum, its extraction, and the perforation of the socket, are generally considered the best mode of making an outlet for the matter. In other cases, you may draw the third or fourth grinder. This is a better plan than that of detaching the cheek from the front surface of the antrum, and applying a small trephine, or other perforating instruments to it.

Fungous Diseases of the Antrum are terrible cases, for they produce a gradual expansion of it, and then such pressure on other parts, as leads to an immense degree of suffering, and often fatal consequences. Thus, the pressure may render the eye amaurotic, or even displace it from the socket; it may force out all the neighbouring teeth; make its way through the palate and alveolar processes into the mouth; fill up the nostril; protrude

through the integuments of the face in a frightful form; or through the cribriform plate of the ethmoid bone, or the orbital process of the frontal bone into the cranium itself, when the patient soon dies in a comatose state. I have seen cases, however, in which the patient did not die, or even become senseless, till the mass of the tumour in the cranium had attained the size of an orange.

Now all these tremendous consequences, if the disease be not medullary sarcoma, as I believe it often is, may be prevented by judicious surgery. These are cases, in which the surgeon must act with decision and courage. If the fungus protrude through the cheek, the whole mass should be cut away without reserve; and, in order to extirpate every portion of it from the interior of the antrum, as much bone must be cut away as is requisite for that purpose. This may be done with a strong knife, a chisel, Hey's saw, the trephine, or Liston's cutting forceps, as may be found most convenient. When the fungus has not completely destroyed the front of the antrum, this cavity must be perforated, and a sufficient extent of bone taken away to allow the fungus to be effectually attacked at its root, and entirely removed. I should not consider the operation of tying the carotid artery a necessary preliminary measure. Desault, who performed some of the boldest and most successful operations of this kind, never had any occasion to tie that artery. The hæmorrhage was always commanded, though it is true he was obliged to use the actual cautery, partly for this purpose, and partly for that of annihilating the surface from which the fungus grew. If the disease were fungus hæmatodes, I believe, that it would be most prudent not to attempt any operation, particularly if the case had made considerable progress.

Cancer of the Lips.—The lips are frequently the seat of troublesome and obstinate ulcerations, sometimes connected with disorder of the general health, but more commonly prevented from healing by the constant motion and friction to which they are subjected.

Some ulcers of the lips, having a foul, and even a malignant appearance, will yield to the internal exhibition of the liquor arsenicalis, iodine, the extract of hemlock, the compound decoct. sarsap., or the compound calomel pill, with occasional purgatives. The most eligible dressings are generally the ointment of the nitrate of mercury, or that of the nitrate of silver, 10 grs to an ounce. A phagedænic ulceration of the mucous membrane of the lips and cheeks, sometimes followed by extensive gangrenous mischief, is termed *can-
crum oris*. It is to be treated on the same principles as other forms of phagedæna.

When cancer takes place, it is almost always in the lower lip, and it is not an uncommon opinion that the pressure and irritation of tobacco pipes give a disposition to the disease, which usually commences in the cellular tissue between the mucous mem-

brane and the skin. The swelling and induration make the disease obvious before the villous surface of the lip cracks transversely, and a thin fluid oozes out. The part then ulcerates and scabs by turns, and ultimately penetrates more deeply, and throws out a fungus. The patient is generally a male subject, above the middle age, and, as I have said, accustomed to smoking. The skin, mucous membrane, and labial glands now form a close compact mass, and the submaxillary lymphatic glands become affected.

Whenever any malignant disease of the lip resists the alterative plans of treatment, which I have specified, it should be extirpated with the knife, before its effects extend to the lymphatic glands. The disease may be removed by an operation resembling that for the cure of hare-lip, or by a semi-lunar incision, though the lower lip, by which you may make a freer removal of the part, than can be effected in the other way. The commissures of the lips, however, should always be spared. A moderate breadth of the lip may be thus taken away with much less subsequent deformity than might be apprehended. Baron Dupuytren and Mr. Travers have both followed this method, and found it answer.

Diseases of Parts in the Mouth.—Wounds of the Tongue are generally transverse, and caused by the violent and spasmodic closure of the teeth, while the tongue is out of the mouth, as sometimes happen in epilepsy, and falls on the chin. Wounds of the tongue, thus produced, may give rise to profuse hæmorrhage; such as would prove fatal if not soon suppressed. As for taking up one of the lingual arteries for this purpose, it would not generally answer, because the wound almost always affects the branches of both. Sometimes such has been the difficulty, that the surgeon has been compelled to apply the actual cautery, or even to pass a double ligature through the centre of the tongue, behind the wound, and then tie each side of the tongue. I may observe, that extirpation of considerable portions of the tongue is not productive of so much imperfection of the voice as might be supposed.

Inflammation and Prodigious Swelling of the Tongue.—The tongue, when in the state of inflammation, may swell so enormously as entirely to fill the cavity of the mouth, protrude between the teeth, and obstruct deglutition and respiration in a most dangerous degree. I remember seeing a soldier's wife at Brussels, whose life was in urgent danger from such an affection of the tongue, brought on by the use of mercury.

Common antiphlogistic treatment will not afford sufficiently prompt relief. The right practice consists in making two or three longitudinal incisions in the dorsum of the tongue. The copious bleeding, which ensues, soon reduces the swelling. In bad cases all medicines and food ought to be given through a flexible gum catheter.

Ulcers and Indurations of the Tongue.—Putting out of consideration the effect of mercury, the irritation of carious teeth, with points and inequalities, is one of the most frequent causes of ulceration of the tongue. Here, gentlemen, it is clear enough, that the right treatment consists in extracting such teeth, or filing away their sharp projections.

Hard tubercles sometimes grow on the dorsum of the tongue, having a narrow pedicle, and a broad mushroom-like head. These may be snipped off with a pair of scissors, or tied, and the part afterwards touched with the nitrate of silver.

I have seen the whole surface of the tongue covered with hard tubercles, some of them in a state of ulceration. On this form of disease, I find, that mercury has considerable effect. Some inveterate ulcerations of the tongue may be cured by the same alterative plans, as I have advised for similar sores on the lips.

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c., &c.

At the Westminster Hospital.

LECTURE XV.

On the Treatment of Impassable Strictures.

GENTLEMEN,—When a stricture is impassable by the bougie, but is permeable by the urine, although it flows with difficulty, I have of late years adopted a mode of practice which has never failed in my hands to clear the urethra, and to effect a passage into the bladder, without giving rise to the evils attendant on the use of caustic, or to the alarm and anxiety which attend the operation of dividing the stricture by any of the means which have been hitherto recommended. The introduction of a bougie into the urethra, and its retention against the surface of a stricture, have invariably been recommended as an effective means of overcoming a retention of urine, by taking off what is usually called a spasm, and causing the contracted part to yield, so that the urine sometimes flows through it, or the bougie gradually dilates it, and passes on into the bladder. On one occasion, some years ago, in a case of difficulty of making water from stricture, I fixed an elastic bougie in the urethra at night, and was much pleased, on calling on the patient early in the morning, to find that it had passed through the stricture, and that the urine flowed readily by the side of it. I was induced to make this trial from the consideration of the effect produced on a stricture by the dilatation of the part immediately anterior to it by Dr. Arnott's dilator, and which is invariably to improve the flow of urine; in other words, to enlarge

the stricture by means of the dilating influence operating on the sounder part in front. One trial naturally led to another, each being more successful than its predecessor, until I supposed I had made a discovery of considerable value; I soon found, however, that the Baron Dupuytren was, and had been, pursuing the same plan in Paris, and, I believe, with as much success.

It might at first sight be supposed that the continued presence of a bougie must give rise to a greater degree of irritation than previously existed, and in all probability to a complete retention of urine. It does, however, exactly the reverse,—it calms the existing irritation, and, after a few hours, if the patient becomes sensible of any difference, it is that his water passes more freely than before. I am quite satisfied of this fact, and believe it to be indisputable as a general rule. The foundation of the method of treatment is built upon it, and if it were not firmly assured the superstructure must fail. The dilatation, nay, the mere separation of the sides of the urethra without any especial dilatation, has an influence of a very favourable kind on a stricture, and may, without being carried farther, effect even a diminution of the contraction in slight cases, so as to allow a bougie to pass with little difficulty. In severe cases, the dilatation of the canal in front of a stricture does but little unless the dilating substance touches the stricture itself, a fact I have had proved, by finding that a bougie may remain for months in a false passage, beginning immediately in front of a stricture, without exerting any perceptible influence upon it.

The best dilating material is a hollow gum elastic bougie, of a medium size, perfectly smooth, and tolerably round at the point, so that it may give as little uneasiness as possible. A very small bougie gives more annoyance than a larger one, is retained with more difficulty, and is more likely to give rise to irritation, in which case it should be removed, and, after a little delay, replaced by a larger one. If this should also give rise to irritation, which rarely occurs, it should be removed, and the irritation subdued by warm fomentations, by opiates, and, perhaps, by the application of a few leeches. There are very few cases which require anything more, provided the patient will be perfectly quiet, live moderately, and preserve the recumbent position, until the irritation has subsided, when he may sit up and walk about his room in his ordinary manner. The bougie is to be fixed in the urethra in the same way as a gum elastic catheter is fixed in the bladder; it should project about one inch beyond the orifice of the urethra, and rather less than more. The point should press against, or rest upon, the stricture with the greatest possible gentleness, so that it may not give rise to inflammation, or to ulceration, and yet should press just so much

as to cause absorption. It is an admitted point in the animal economy, that new formed parts, whether laid down in reparation or in disease, do not resist a stimulus in the same manner as parts of original formation. They are, in fact, removed by the action of the absorbents under the application of a stimulus, which has little or no influence on those parts which have undergone no change, and are co-eval with the existence of the individual. The pressure made by the point of the bougie, and which ought always to be an elastic one, should therefore be nicely regulated, so that it may do this and no more. It is a point which requires attention, and some little experience, although a due knowledge of it is soon acquired. It should never be so great as to give pain, or indeed uneasiness, and yet it should be continual. The patient readily learns what is wanted, and, as he can feel when the surgeon cannot, he soon understands how to manage the bougie himself, and can take it out, wash it, change it, or replace it, as he pleases. If he is a very restless, fretful, or naturally irritable man, it may prevent sleep, or prove inconvenient, in either of which cases it may be removed for two or three hours, at the pleasure of the individual, whose private affairs may otherwise render this indulgence necessary. It does no harm, it is merely a little delay, which prolongs the time requisite to effect a cure.

If the pressure be made by a stiff unyielding instrument, inflammation and ulceration may be the consequence, and many evils may be the result; but then this is the abuse of the practice, not the adoption of it, and forms no part of that which I have recommended. The pressure, according to my views, must be so nicely regulated as to cause absorption, but not to give rise to ulceration, and I firmly believe that it may be graduated in such a manner, as to fulfil these intentions most accurately. When the objects stated are duly accomplished, the patient soon perceives that the stream of urine is enlarged, that it comes more freely, and that the general irritation of the bladder and the neighbouring parts has diminished. The principal and most satisfactory sign of amendment is the more ready flow of the urine, and although the bougie should not advance, the amendment on this point is often progressive, until at last the bougie is either found to have passed through the stricture unknown to the patient, or is gently pressed through by his own hand, or by that of the surgeon. The time necessary for the accomplishment of this object must be longer or shorter, according to the extent and nature of the disease, and the state of the constitution of the patient. The object is effected in some cases in from three to six days, in others the progress is slow, although evident, and it may require as many weeks, but in no case that I have met with has the practice failed. When the canal is thus rendered pervious, the cure is only half completed, although the most difficult and dangerous part has been accomplished. The

stricture has yielded in its centre, but not in its circumference, and two courses may be pursued; one is to increase the size of the bougie, so that it may press on the circumference of the anterior part of the stricture until it causes its removal, the other is effected by passing the bougie through the stricture, and gradually enlarging it, thus pressing on the inner circumference, in preference to its anterior surface, which method I prefer. When the bougie has passed through the stricture, I always carry it into the bladder, and then replace it by a catheter, the use of which may or may not be continued at the pleasure of the surgeon. A catheter is not necessary to draw off the urine, as it flows as readily by the side of the bougie, but it proves that the instrument is in the bladder, and it is always a great satisfaction both to the patient and surgeon, to see the urine flow through it. I have a gentleman now under my care, whose stricture has been overcome in this way, but in whom the point of a small bougie almost always enters into one of the openings of the ejaculatory ducts, and that of a larger catches on it, and will not often proceed without a little management. If the error be committed of allowing the bougie to lodge in one of these openings, inflammation will in all probability be communicated to the testis, and there is always a chance of such an accident occurring when the orifices of these ducts are irritated even by the instrument resting upon them. If a catheter is used, the eye of the instrument should pass fairly into the bladder for half an inch at least, but it is better to use one made with a hole at the extremity; and when the instrument is not in the bladder, and it cannot always be borne there, it should be withdrawn, so as to lie in the membranous part of the urethra, with the point near to, but not irritating, the prostate gland. It will often remain in that situation quietly when it cannot be advanced without producing the greatest irritation. In some instances where this has taken place, the instrument must be altogether withdrawn, until it has been subdued, when it may be cautiously replaced. The greatest evil, however, usually arises from increasing the size of the bougie too rapidly, and this is a point to which the greatest attention must be paid, whilst it is the error into which both surgeon and patient most frequently fall, as I have stated when treating of the cure by dilatation. It is, then, the point which requires the greatest nicety of management, and this can only be acquired by observation founded on experience. The irritability of the inside of the stricture, and the part adjacent but posterior to it, is sometimes greatly augmented by the urine which passes over them. This is frequently diminished in quantity as well as altered in quality, being loaded with salts and other matters which render it extremely irritating, and, unless it be brought more to its natural state, little or no progress will be made in completing

the cure. The diet of the patient must be then an object of particular attention, and the urine must be tested from time to time, in order to ascertain its nature, and the general treatment must be strictly continued until it is found to have lost its irritating qualities, when there will be a fair prospect of completing the cure. The presence of the bougie gives rise to a discharge, which is greater or less according to the state of irritability of the patient, but it is never accompanied by pain, unless inflammation is brought on either by accidental circumstances, or from the size of the bougie being too rapidly increased, so as to distend the canal beyond what it can readily bear.

When the urethra is rendered pervious, the attempt to enlarge the strictured part too rapidly always brings on pain, irritation of the neck of the bladder, and so much suffering that it cannot be borne, and the large bougie must be withdrawn, and time must be lost before one a size or two smaller can be used in its stead. This, as I have stated, is the error you will be most likely to fall into, and it is therefore the one you must most carefully avoid. If you will recollect what I have said on the question of effecting a permanent cure by dilatation, you will perceive that a permanent cure cannot be accomplished unless a bougie is passed occasionally, so as to take off the disposition for relapse, which lasts for a considerable time, and which must be always borne in mind. I have in my hand the history of the cases of three medical men who have been cured in this way; they are of great interest, and particularly the first; and I selected those of medical men from a great number, because it may be supposed they understood better what they were about than other men, and that they are written by themselves.

June 20th, 1831. A. S—, M.D., aged 38, has had stricture in the urethra for 18 years past, and has been under the care of many of the most eminent surgeons, at different times; but no instrument has ever yet been passed into the bladder, with the exception of a very fine catgut bougie, which Mr. Piele, of Dublin, at one time passed, but could never introduce again.

In 1824, he was affected with severe rigors and fever, recurring twice a-week: and about this time retention of urine for forty-eight hours occurred. The caustic bougie was repeatedly used, and had to be discontinued on account of the rigors that occurred after each application of it. After this, in 1825, the dilating plan was followed for some months with an evident improvement in the general health, and an increased stream of urine. From 1825 to 1830 the complaint was much better; occasional attacks of inflammation in the urethra occurred, which were generally pretty easily got under by the application of leeches to the perineum, and the use of the hip-bath. On August 14th, 1830, was seized with great pain and irritation about the neck

of the bladder, and great difficulty in passing water, which came in very small quantity at a time with great straining; these symptoms did not yield to the repeated application of leeches, the hip-bath, anodyne enemata, and suppositories of opium and extract of belladonna, but continued to increase and become more alarming, until the 22nd, when urinary coma came on, and it was deemed necessary to puncture the bladder above the pubes, which was done without delay, and a very large quantity of thick stinking mucous urine drawn off; in about three hours afterwards the coma subsided, and things seemed going on well for a couple of days, when an abscess began to form in the perineum; this increased for a couple of days, and fluctuation being perceived an incision was made into it, and a quantity of extremely stinking matter discharged. In a day or two afterwards another abscess made its appearance on the right side of the scrotum, into which an incision was made, and a table-spoonful of pus escaped; after this another abscess formed in the right groin, and was opened as soon as fluctuation was perceived. These sores all healed kindly and well in the course of eight or nine weeks; but during this time a very severe rheumatic fever came on, which lasted fourteen or fifteen days, and was attended with great suffering during that time. The recovery after this was very slow; the urine began to come away a few drops at a time by the natural passage; the catheter, which was introduced through the puncture into the bladder, was changed about once a-week. It was now attempted to dilate the urethra by the occasional introduction of bougies, and afterwards of graduated sounds, which has been continued up to the present time, but without being able to get any instrument through the stricture into the bladder.

June 22nd, 1831. Mr. Guthrie introduced a gum-elastic catheter down to the stricture, and (having fastened it by a belt round the penis below the glans) left it there with its point pressing on the stricture, and about an inch projecting beyond the extremity of the penis. The passing of the instrument occasioned some pain, and in the evening there was heat and uneasiness along the course of the urethra, which was relieved by taking a draught with 25 drops of the Lancaster Black Drop.

23rd. Passed a quiet night; slept well towards morning; the instrument has kept well in its place; some uneasiness and irritation in the urethra; pulse a little hurried; having kept very quiet in bed all day the uneasiness and irritation were nearly gone in the evening; when the instrument was withdrawn, washed, and replaced; repeated the anodyne draughts; and took a pill of extract of colocyth, five grains.

24th. Slept well; catheter kept well in its place, and caused very little uneasiness; kept quiet in bed all day; removed, washed, and re-introduced the catheter; draughts and pill repeated at bed time.

25th. Going on as yesterday; keeping very quiet in bed.

26th and 27th. Keeping very quiet; the catheter is going a little farther in.

28th. Had an uneasy night; pain and heat along the urethra, and irritation at neck of bladder, which were relieved by removing the cork from the puncture-catheter, and allowing the urine to trickle away in drops for the space of four hours; repeated the pill and anodyne draughts, with forty drops of the Lancaster black drop.

29th. Heat and pain of the urethra and irritation of the bladder subsided; parts feel easy, and the instrument has gone further in; draught and pill repeated at bed time.

30th. Instrument still farther in; draught and pill repeated.

July 1st. The instrument is still advancing, and not causing any uneasiness; draught and pill repeated.

2nd. Puncture catheter changed, the other advancing; repeated draught and pill.

3rd. Instrument still advancing a little; no uneasiness; draught and pill omitted.

4th. Slept well; instrument advancing.

6th. Instrument in as far as it can go; changed for a longer; it appears, on measurement, that it has penetrated an inch since its first introduction.

7th. The new instrument keeps its place, and produces no inconvenience.

8th, 9th, and 10th. Going on well; no uneasiness; keeping very quiet.

11th. A good deal of irritation at the neck of the bladder in the night, so that the instrument had to be withdrawn, after which some urine came by the urethra, two or three times with considerable straining, and then close on half a pint in a better stream than had been made for many years, and with much less exertion.

12th. Made water in an improved stream frequently by the natural passage.

13th, 14th, and 15th. Stream of urine continues to improve.

16th. A small-sized gum-elastic catheter passed with tolerable ease into the bladder, and was left in.

17th. Some uneasiness about the neck of the bladder; urine runs both through and along the side of the catheter.

18th. Uneasiness and cutting sensation about the neck of the bladder.

19th. No. 2 catheter withdrawn and No. 4 introduced with little difficulty into the bladder.

20th. Uneasiness about the neck of the bladder much diminished since the introduction of No. 4; the urine runs both through and along the sides of it.

21st. No. 4 withdrawn and No. 6 introduced with little difficulty in its stead.

22nd. Urine ran along the sides of the catheter during the night.

23rd. No. 6 withdrawn, No. 8 introduced with little difficulty, but occasioned a sensation

of great distension along the course of the urethra.

24th. In the afternoon considerable pain and throbbing in the perineum; withdrew the catheter until bed time, and then put in the short instrument, used previous to the introduction of No. 2; urine passed in a large stream when the catheter was out.

25th. Withdrew the short instrument and introduced No. 8 with great facility; some pain in the perineum in the afternoon.

26th. Pain in perineum, which increased with a good deal of swelling towards the evening, when the catheter was withdrawn. Eight leeches, and afterwards a poultice, applied to the part. An anodyne draught and pill at bedtime.

27th. Swelling increased; poultice continued; repeat the draught.

28th. Tumour broke and discharged some matter; poultice continued.

29th. Discharge continues; poultice continued. Introduced No. 6 catheter, and kept it in six hours.

30th. Discharge much diminished. Catheter would not pass into the bladder. Great needling, which was relieved by keeping the cork out of the puncture-catheter for two hours.

31st. Catheter could not be introduced. Introduced the short instrument at bedtime. An anodyne enema taken during the night.

Aug. 1st. Catheter No. 6 passed easily into the bladder.

2nd. No. 6 still in; some irritation at the neck of the bladder. Took an anodyne enema, and kept the puncture-catheter cork out for two hours.

3rd. No uneasiness to-day. No. 6 still in.

4th. Catheter No. 7 introduced. At night great uneasiness about the neck of the bladder occurring at short intervals; took an anodyne enema, which not removing the uneasiness, the catheter was withdrawn, and the short one introduced an hour afterwards, and worn in all night.

5th. No uneasiness; introduced No. 7 catheter again.

6th. No uneasiness; withdrew the catheter and passed water in a large stream three or four times. Introduced the short instrument at bedtime.

7th. No. 8 introduced with ease; a good deal of irritation at night, which was relieved by an anodyne enema and keeping the cork out of the puncture-catheter for about an hour.

8th. Had a good night after the enema; quite easy all day.

9th. No. 8 still in; quite easy.

10th. No. 9 pewter catheter passed easily, but occasioned so much pain about the neck of the bladder that it was withdrawn in two or three minutes.

11th. No. 8 gum catheter introduced.

12th. A No. 10 pewter catheter shortened was introduced with ease, which occasioned a good deal of irritation and needling at night; relieved by an anodyne enema.

13th. Slept well after the enema; easy to-day.

14th. Removed the pewter No. 10, and introduced an elastic gum of the same size. A little uneasiness and needing at night; relieved by an anodyne enema.

15th. Got ease and slept well after enema. Withdrew the catheter in the evening and walked out for an hour; greatly fatigued after the walk; a sensation of rawness along the urethra. No 10 gum catheter introduced at bedtime.

16th. No. 10 removed and No. 11 pewter catheter introduced without difficulty; after being in some time there was uneasiness near the neck of the bladder, which was relieved by an anodyne enema.

17th. Slept well; quite easy to-day; withdrew No. 11 in the evening and walked out for an hour. Great rawness along the urethra after making water, which continued all the evening.

18th. Kept out the catheter all day; urethra feels very raw.

19th. No. 10 elastic catheter introduced, as No. 11 pewter would not pass.

20th. Withdrew the instrument in the evening, and introduced it at bedtime.

21st. No. 12 pewter catheter was passed without difficulty into the bladder, but produced so much uneasiness that it was withdrawn in the course of two hours and a half, and a gum elastic one of the same size introduced in its place.

22nd. Some pain in the perineum; withdrew the catheter, and applied seven leeches; an anodyne enema at night.

23rd. Slept well; pain quite gone; No. 12 flexible catheter introduced into the bladder.

24th. No. 12 in.

25th. No. 12 still in; a good deal of irritation about the bladder; an anodyne enema at bed-time.

26th. Withdrew the catheter, and walked out during the day; introduced it again in the evening, and kept it in fourteen hours.

27th. Catheter in for twelve hours to-day.

28th. In for ten hours.

29th. In for eight hours; withdrew the catheter from the puncture above the pubes entirely, which had been gradually diminished in size for the last four or five changes.

30th. Catheter worn six hours. Some urine came away through the puncture during the night.

31st. Only a few drops of urine passed through the puncture to-day; comes by the urethra in a very large stream.

Sept. 1st. Catheter No. 12 passes with great ease; puncture entirely healed.

2nd. Catheter No. 12 in for two hours, urine comes away in a full stream, and the health is better than it has been for the last ten years.

On the 21st Dec. 1833, he writes to me, saying, that he is quite well, passes his urine

in a free, full stream, and introduces a No. 11 silver bougie once a-week.

For eleven months this gentleman scarcely passed a drop of water through the urethra, but wore a gum-elastic catheter in the wound above the pubes, which he fastened with sticking plaster against the abdomen above the umbilicus; and through this he made water when he felt a desire, and which he experienced in the natural and usual way. He felt his situation so wretched, that he came to London determined to submit to anything which might place his life even in jeopardy, if the hope of a cure could be held out to him.

The last observation I shall address to you on this subject is, to beg you will never forget that no one method of treatment will succeed in every instance, and that he is the best practitioner who can avail himself of, and duly apply, the various means with which he is acquainted to each particular case.

REFUTATION

OF THE DOCTRINE OF CONTAGION

By Historical and Personal Evidence.

BY R. TYTLER, M.D.

Delivered before the Medico-Botanical Society of London, May, 13th, 1834.

GENTLEMEN,—I have to return, to the President and the members of this Society, my best thanks for the opportunity you have afforded me this evening, of submitting for your consideration the principles of anew system of nosology for the classification of diseases, hitherto imagined to be of the most contagious description. I candidly confess, that while I view with respect the labours of other Societies, it is to the Medico-Botanical Society alone I look for the real improvement and advancement of medical science. Because the investigation of the qualities of herbs, of plants, and of vegetables, has, in all ages, constituted the legitimate province of the physician; and if I can establish, to the satisfaction of this Society, that a grievous error has, during a long lapse of years, been allowed to creep into our science, and to corrupt medicine to its very core, destroying and polluting the fountains of the healing art; and that this error can alone be corrected by means of the investigation and encouragement of medical botany,—I doubt not, but that the subject, I am about to develop to your notice, will be deemed deserving of the most serious consideration of the members of this Society. It is, gentlemen, in one word, my object to slay the monster of plague and cholera—*contagion*; to immolate this hideous delusion on the altar of knowledge; and by driving his pestiferous carcase far from the precincts of science, prevent for ever this dragon

of corruption and error again tainting medicine with his hateful and baneful presence. The work which I hold in my hand proves the necessity of my adopting the course, that you have this night permitted me to pursue. It is, gentlemen, a Treatise on the Cholera Morbus, by M. Lombard, of Geneva, and, commencing with my name, he states that the first case of the "new plague" was seen by myself; and after detailing the manner in which the disease arose at Jessore, the writer suddenly drops all the facts which have been accumulated by myself, demonstrating the origin of this dreadful distemper to proceed from the use of vitiated rice; and as if no such facts were in existence, and as if no researches had taken place by me respecting the origin and cause of a disease, that commenced in my own practice, and under my own eyes, the author proceeds to reason upon the existence of cholera as depending solely upon contagion, and its propagation as being wholly inseparable from the same fanciful cause. Thus, standing as my name does at the very outset of M. Lombard's work, I am in a manner rendered responsible for opinions, which are directly the reverse of my own on this most momentous topic; and it must appear to the reader of that production, especially if he should be unacquainted with the discussion that occurred, during the last year, in the Medical Society of London, and if he never should have fallen in with my writings upon the nature and origin of Epidemic Cholera, or *Morbus Oryzeus*,—that I absolutely advocate the doctrine of rice disease having been propagated by infection;—than which a more absolute delusion is not in existence. I therefore, gentlemen, protest against all medical writings, such as this of M. Lombard's, which forsake facts, and reason, without the slightest reference to established and known circumstances, upon a preconceived theory, as if that theory constituted demonstrated and unalterable truth. It may be said, that it is somewhat indecorous to pass comments upon an absent individual; but his book is present, and it is the principles of the work against which I contend.

Gentlemen, I well know that the Asiatic cholera is not contagious. I saw the first case of the malady, which had been brought to the notice of any medical officer, in August, 1817, at Jessore, and consequently am fully entitled and qualified to give an opinion upon this question. The idea of that disease being infectious, or propagated by contagion, is absolutely ridiculous; and I am as positive as that I stand on this spot, or that I see the President in that chair, that the Asiatic cholera is not contagious, and that its propagation proceeds entirely from the use of deteriorated rice—a specimen of which I now lay before you. It is unnecessary for me again to go over the ground, which before the Medical Society I travelled, in the months of last September and October. But it is proper I should men-

tion, that the fact of this deteriorated rice being clarified or bleached has, since the discussion of last year, been fully established by means of documents which have appeared in the *Lancet*. That this rice is manufactured into the form of tapioca and arrow-root there can be no doubt; and hence this part of the subject, which refers to the adulteration of articles recommended by the physician as medicinal aliments for the infant and the invalid, cannot be considered otherwise than as deserving of your profoundest attention. Since last year, also, it has been ascertained that the shelly covering named *kun* and *koora*, which exists between the outer husk and the grain of the rice, is imbued with an oleaginous substance, suspected to contain the constituents that distinguish the croton oil. This fact, then, leads us at once to understand the effects produced by this substance upon the stomach and bowels of those who partake of it for food; and the extent of a disease, produced by the admission of a deleterious substance of this kind, will of course become equally intelligible, when we reflect upon the immense quantities of this deteriorated grain, which are annually imported into this, and other countries, from the East. Again, it is to be observed, that it is not into those places where the grain is first imported, that the *Morbus Oryzeus* necessarily appears, but in those spots where the deteriorated grain is used for food. For example, the vitiated grain being imported into Liverpool, but having been carried by means of the rail-road to Manchester, and given in that town as food to the manufacturers, or at Newcastle, where it was consumed by the colliers, the disorder was manifested previous to its appearance at Liverpool. In like manner the deteriorated grain is imported from India into Greenock, and from that port the rice being carried, by means of the Caledonian canal, through the Highlands of Scotland, there, and when least looked for,—the *Morbus Oryzeus*,—entirely owing to the employment for food of deteriorated rice exported from India, was produced. Hence, wherever the vitiated rice found its way, there the cholera or *Morbus Oryzeus* made its appearance, and nowhere else.

Having thus established the real cause upon which the dreaded and destructive cholera depends for its existence and prevalence, I proceed to explain the principles of the New System of Nosology, which has this evening been laid before the Society. It is proper I should notice, that this system is the natural consequence of the facts, stated by me regarding the terrible results arising from the use of deteriorated grain. This nosology is the inevitable sequel of the Oryzean system, and comprises the conclusions to which I was led from reflection upon the facts, accumulated by me during my researches into the dreadful effects produced by vitiated rice. The work was published in Latin and English, in Hindoostan, so

far back as the year 1821, and a copy transmitted to England by my late friend Dr. Adam, Secretary to the Medical Board of Bengal, was reprinted in one of the medical periodicals of the day, accompanied with commendations passed upon the nosology on account of its originality. But the subject was allowed to drop. The work in which it appeared is at present, I believe, defunct; it never attracted any notice from the medical practitioners of Great Britain, and, consequently this nosology may be considered as wholly new to this Society.

If, gentlemen, contagion be an error, as I contend it is, here is a dreadful and most mischievous error, indeed, permitted to pervade the whole of our science. I view, in common with my medical brethren, with intense interest the proceedings, which the legislature of the country have thought proper to adopt with reference to medical reform. But contemplating, as I do, the baneful doctrine of *contagion*, as a most dreadful and destructive delusion, which tends to the establishment of the horrible quarantine laws, and leads to the violation of every duty of humanity, I admit it is a matter of comparative indifference to me, whether facilities for teaching this error be conferred upon the University of London, or be retained by those of Oxford and Cambridge, Aberdeen, St. Andrew's, Edinburgh, or Glasgow. It is the science itself which requires to be reformed, and this beneficial alteration can alone be effected by the members of the profession themselves. Gentlemen, I have in vain looked into the most ancient authors for a glimpse of the *modern* doctrine of contagion; and I believe that doctrine, as it at present exists, to be first *distinctly* found in the writings of Dr. Mead. By Lady Mary Wortley Montague, who was the first to introduce the practice of inoculation for small-pox into this country, we are informed that parties, similar to those of pleasure in Great Britain, are formed in Turkey for the purpose of inoculation. Such a statement carries absurdity on its face; and as I shall presently show, that although inoculation does prevail all over the East, yet that operation takes place with a view wholly different to any idea of an individual being secured by its effects from contagious variola. The writings of Moses I hold to be the most ancient records in the hands of the present race of men, at least I can myself find none, nor can I hear of any book which can, in the remotest degree, compete with the Pentateuch in point of antiquity. In the Mosaic writings, accordingly, there are statements made regarding a *burning fever*, *inflammation*, and *pestilence*, the identical diseases which are, by modern physicians, maintained to be contagious, yet not the remotest allusion to contagion is traceable throughout the whole of the Pentateuch. Nor is a vestige of the same doctrine discoverable in any part of Scriptures; but, as we shall presently see,

the doctrine of Divine wrath, originating pestilences, being divulged in the Holy Scriptures, this doctrine has been contorted and perverted into the modern dogma of contagion, which, although comprising an absolute perversion of the truth, yet to doubt its existence is reckoned little else than a medical heresy. In the writings of the father of medicine, Hippocrates, not the slightest hint is given of the same fiction. If contagion were a truth, how comes it that the venerable founder of the healing art should have omitted such a conspicuous fact in those splendid aphorisms, each of which appears to contain the concentrated wisdom of ages? In the New Testament, so far from perceiving contagion divulged, we find the Divine Saviour of mankind himself, whom every Christian acknowledges to be Jehovah incarnate, the Deity Loquens, directing it to be the duty of his followers to visit the sick. "I was sick, and ye visited me," is the language of Christ; "I was naked, and ye clothed me," is the doctrine which is commanded by Jesus. Yet what says contagion?—do not visit the sick, for if you do, you will either receive the disease yourself; or convey it to another; do not clothe the naked, for woollen garments are the recipients and communicants of contagion. Hence the doctrine of the Saviour and the doctrine of contagion are diametrically opposed to each other; and as the former is the doctrine of God himself, the contrary doctrine must have been propounded by the author of evil, the Devil, who was a liar from the beginning, and the father of it. And as the tree is known by its fruit, so is this dreadful doctrine, which aggravates the misery and tends so fearfully to the destruction of the human race, distinctly traceable to its proper and mendacious parent,—the father of lies. In the writings of Celsus, who was contemporary with the Apostles, no trace of contagion is discovered; we are equally at a loss to perceive it in Galen. Avicenna, the first Arabian physician, gives no intimation of such an opinion; and Rhazes, who is the first to give any account of the small-pox, makes no mention of such cause of that disease being in existence, and explains the prevalence of variola upon wholly different principles. In a word, no allusion is made to the fiction of contagion till posterior to the Reformation, when an idea was broached, as is understood, with the political intent of preventing the Emperor from approaching the spot where the Pope and Cardinals were assembled, that a formidable malady raged in the town, and would descend on those who came within the consecrated limits. Still this did not comprise the modern notion of contagion; and it is in the writings of Mead, where we distinctly find the doctrine of propagation of disease from one body to another, and the contagion, by means of clothes, &c., conveyed from house to house, and town to town, that I imagine this untenable figment is first un-

doubtedly published. It is commonly asserted, that in the East Indies no contagious malady is in existence; yet throughout Hindoostan, the diseases, considered in this country to be contagious, are as prevalent as in Europe. In the course of practice in India, I have witnessed, and that, too, subsequent to vaccination, the most terrible cases of confluent small-pox I have ever in my life beheld. In Hindoostan I have, with the exception of buboes in the arm-pits and groins, witnessed a distemper, in every respect bearing the most striking resemblance to Egyptian plague; and typhus gravior, commonly named *jungle*, or *bilious fever*, is, in India, of every day occurrence, while terrific cases of measles appear regularly in India as the cold weather sets in. During the time I was in medical charge of the army in Arracan, I witnessed typhus icteroides in its worst form. Cases of that disease, which prevailed amongst the Europeans in that quarter, were officially stated to me by two assistant-surgeons to bear exact resemblance,—in fact, that they constituted a disease precisely identical with yellow fever, which had, by one of those gentlemen, been seen in America, and by the other, in the vicinity of London. Then, since the diseases are prevalent in India, which in Europe are considered to be highly contagious, why should not contagion be there equally prevalent, as it is asserted to be in this country and America? We are told, that this amazing difference is imputable to the effects of climate, yet Hindoostan embraces every variety of climate; and there we have the contagious diseases of Europe and America asserted not to have reference to either infection or contagion. The fact is, that in India prevails the original idea of contagion, which supersedes the word as employed by us, and thus the natives afford an explanation of diseases upon principles, which, I am now about to show, have travelled into Europe, and assumed the form of *contagion*, without the word itself, or our view of *contagion*, being recognisable by them. The primeval idea of the woman, the tree, the serpent, and death being associated, is as well known in the East, as it is in Great Britain. This woman—the great female parent of mankind—is depicted in a two-fold capacity;—in one she is the genial queen of gardens, fruits, corn, and flowers; in the other, she is a terrible destructive demon, introducing death, and presiding over the grave, and hell. Hence, under the former personification, she is Ceres and Proserpine gathering flowers, and in the other is represented as the wife of Pluto, and grisly empress of the infernal regions. This goddess is well known in India, and is universally held in reverence by the natives under the names of Devi, Kalee, and Seetillah. During the prevalence of the cholera, she was worshipped under the denomination of the *Onlah Bebee*, or *Lady Oolah*, or “presiding goddess of upwards and downwards.” She is the goddess of small-

pox, which is named *mallah*. In the ancient Kawi language of the Island of Java, *mallah* signifies “the eye,” and is hence applied to the sun, which luminary is termed *mallah eare*, or “eye of the day,” an expression coincident with *mattare*, translated into Greek by the term *Heliopolis*, or city of the sun, in Egypt; and hence, also, from the same word, *mattare*, the name of the native kingdom of Java, is derived. It may be asked what connexion has small-pox with the sun, the moon, or the stars? The answer is obvious,—the goddess Devi is the moon, Diana, or Hecate: she presides over the stars, and is arrayed in robes decorated with the constellations. When, therefore, this queen of heaven, or night, in her form of Seetillah, descends into the human body, her stars, or planets, must make their appearance, in the same manner that the constellations are attendant on the radiant Urania. These stars and blossoms are, therefore, imagined to be seen in the pustules of small-pox; and terms, in allusion to this appearance of Seetillah, still constitute the leading expressions of medical science, in reference to inflammatory and eruptive diseases. Thus, physicians speak of *the efflorescence* and *star* surrounding a pustule; hence the pustule is said to advance to *maturity*, and to *ripen*, and *dry*, precisely in the mode in which the same terms are applied to fruits and flowers. The notion of the Indians is, therefore, that small-pox, in every instance, is caused by the descent of Seetillah into the body; and the goddess must not be provoked or tempted on the occasion of her visit and appearance in a family. Whilst I held the office of Superintendent of Vaccination at Allahabad in Hindoostan, the greatest obstacles on the part of the natives existed against the introduction of cow-pox. At first, these people asserted that, by the government, a mark was placed on the arms of the children, in order, at a future period, that they should be recognised and claimed for slaves. This idea speedily subsided, and then the real cause of the aversion to cow-pox became disclosed. Inoculation, unless performed with peculiar ceremonies, and under particular circumstances, is conceived to be a provocation offered to Seetillah, the implacable death-dealing goddess. Therefore, if inoculation be performed, unaccompanied with certain propitiatory offerings and superstitious ceremonies, according to the Hindoos, the presence of Seetillah, in her most wrathful form, is to be dreaded; and hence, after the performance of vaccine inoculation upon the arm of a child, I have seen the parents performing a *ponjah* in the centre of a cross-road, with the intent of propitiating the goddess, and deprecating the effusion of wrath which they imagined had been provoked by them, in allowing inoculation without the preceding and accustomed offerings.

The idea, therefore, of small-pox in the shape of a contagious disease emanating from one body and entering into another, is far

removed from the mind of a Hindoo. It is the presence of a presiding goddess, who, at her own free will and pleasure, shifts her habitation when and where she pleases, that produces the disease; and, whenever inoculation takes place voluntarily among themselves, the operation is considered in the light of a propitiation to Seetillah, the person on whom the operation is performed becoming enrolled among the number of her victims or votaries. Hence one great difficulty which existed, and does still exist, to the admission, on the part of a Hindoo, of vaccination being a preventive of small-pox, because, having his own pre-determined and inflexible notions on the subject of *mallah*, its causes and consequences, he is unable to comprehend in what manner inoculation, in any form, can prevent an advent or visit from Seetillah.

The first change which the *Oolah Bebee*, or the lady of small-pox underwent in her progress towards Europe, was from the hands of the Mussulmans. This race is known to have comprised the most furious iconoclasts that probably ever made their appearance in the world. The idols of India were at once their aversion and dread; and the merciless destruction, poured forth by them upon the stocks and stones of Hindoostan, fully proved that the destruction of those images and monuments of idolatry, was as much dictated by their dread of an evil and vindictive influence being resident in those objects of idolatrous veneration, as implicit obedience to the commands of the Koran. The superstitious influence ascribed by the Hindoos to Devi, Kalee, and Seetillah, passed to the hosts of the Mahomedans, by whom it was retained and cherished beneath the form of Roh or Rokh, spirit, or pneuma. This Rokh, in allusion to the fluttering of the Divine Roh, or Spirit, on the surface of the abyss at the period of creation, becomes embodied into the fanciful representation of the rokh, an imaginary bird, whose egg is pregnant with death. This roh, or pneuma, or evil spirit, or pestilential aerial influence, from the Mussulmans next passed into Europe, and finally, according to later notions, and the discoveries attendant on pneumatology, assumed its modern dress of contagion. Such, however, are the changes, and variety of opinions received by modern physicians with reference to the contagious pneuma, fomes, or roh, that Seetillah, were she present in England, would hardly be able to recognise herself in the masquerade forms and Harlequin disguises, which, in the hands of the modern disciples of *Æsculapius*, she has been made to assume. In the midst of this falsification of knowledge, by means of the perversion of science, proceeding from the prevalence of idolatry and superstition, it is remarkable that the true cause, upon which the real origin of pestilence depends, has actually descended to us from remotest antiquity. Thus in Holy Writ, along with the inflammation, and pestilence, and burn-

ing, is associated *mildew*, or the destruction of grain, which is denounced by Jehovah as comprising one of the most tremendous judgments awaiting His rebellious people. In the first book of Samuel is described the pestilence which overtook the people of Bethshemesh, and which destroyed upwards of 50,000 persons. This tremendous visitation occurred at the time of the reaping of the harvest, consequently it happened as those persons, who were reaping their wheat in the valley, were making use of the new grain, and the symptoms of this dreadful distemper, as we learn from Josephus, were accompanied with discharges of undigested grain. The fearful pestilence by which 70,000 persons perished, which is mentioned in the 2nd book of Samuel, and 1st book of Chronicles, also occurred at the period of harvest, for "Ornan was threshing wheat," when the plague stayed. Here, then, we gather from Scripture the association of the origin of plagues and pestilences with *mildew* and the presence of grain. The most ancient pestilence on record, detailed in the writings of classical or profane authors, is the distemper by which, during the reign of King Athamas, Thebes was desolated, and occasioned the Argonautic expedition with the view of obtaining the golden fleece, and consulting the oracle at Colchis. That plague is said to have been occasioned by the wrath of Ino, who, to revenge herself on Nephele, produced the pestilence *by poisoning all the grain which had been sown in the earth*. But, in fact, Nephele is "a cloud;" and here, then, in this tradition of an universal malady arising from a general cause, is shadowed forth the vitiation of grain by means of clouds, showers, and inclement seasons, as well as, in the same legend, is detailed the terrible effects which grain so distempered is capable of occasioning. Josephus records the fearful pestilences which accompanied the famines and neglect of agriculture that prevailed during the Jewish wars. Many similar pestilences, arising from similar causes, are on record, till the days of Justinian, when the tremendous plague occurred that ravaged the Roman empire, and was accompanied by a total neglect and suspension of agricultural operations. The sweating sickness was introduced into England by the army of Henry VII., who were in extremity for want of supplies, and it continued during the period this country was ravaged with the desolating calamity of civil war. It is needless, gentlemen, to multiply instances, but, from the earliest period downwards to the present times, famines, vitiation of crops, and pestilences, proceed hand in hand. The famine, or vitiation of the harvest, first precedes, and the plague occurs precisely in the relation of cause and effect. In the year 1816, the crops, owing to inclement seasons, were injured in Great Britain, and that year was remarkable for the occurrence of typhus fever, small-pox, and varioloid disease, in all their destructive forms. In the following year, the crops, by the agency

of the inclement weather and other causes, were vitiated in Bengal, the great rice mart of the universe, and this vitiation was succeeded by the cholera, which has spread universally coincident with the employment of the vitiated grain; and along with the cholera in India were witnessed small-pox, and typhus-fever, characterised by the most terrible symptoms which attend the progress of these maladies. Mature and great reflection on these facts has, therefore, led me to frame the "*exemplum parvulum nosologici novi*," which is now in your hands. It is based upon the principle that in vegetables, under certain circumstances, a matter exists incapable of assimilating with the animal blood. When this matter, whatever it may be, either excess or deficiency of life, is absorbed into the circulation, disease follows, because nature attempts to expel it from the animal body. If the *vis naturæ* be sufficient for this purpose, the patient recovers, but if the strength of his constitution be unequal to the effort, the patient dies, affected with symptoms which are dependent upon the nature of the organ or viscus to which, in the course of circulation, the noxious vegetable matter is determined. If, for example, the noxious matter be determined to the upper part of the stomach and bowels, and there produce violent inflammation and gangrene, the result is cholera morbus in its worst form; if the inflammation be in minor degree, the disease is typhus gravior or mitior, according to the extent of the inflammation which is present in the villous coats of the alimentary canal. If the determination should be to the liver, then an augmented secretion of bile is the consequence, and the disease assumes the aspect of yellow fever. If the determination be to the lower extremity of the intestines, the consequence is dysentery, if to the eye, ophthalmia, and should the result be gangrene on the surface of the body, the distemper is dry gangrene, and confluent small-pox, and *mal des ardens*.

It is to the presence of this principle in vegetables, comprising matter unassimilable with the animal blood, to which I am desirous of directing the attention of this Society. This doctrine is in fact deducible from highest antiquity, and, whilst it has been overlooked by modern physicians, it is nevertheless in a manner preserved by the Jewish writers of the present day. For one of the most learned followers of the Mosaic Law in London, Mr. Goodman, in a late work, entitled the Faith of Israel, expressly lays down the one principle, that vegetables derive their sustenance from the earth, and animals derive their life from the vegetables. Accordingly this presents us with the real explanation of the phenomena of life, and if the vegetable matter be unassimilable with the blood, it is plain that disease must follow, till its expulsion from the system take place. But of all vegetable matter grain is the substance, from which the principle of life is derived in greatest abundance to ani-

mals, and of the grains which afford subsistence to man, wheat stands in the highest rank, and next to it barley. We have all heard of the nutritious qualities of oatmeal; but let us view the inhabitants of the Highlands of Scotland, whilst living upon that farinaceous aliment. The intellect of these hardy mountaineers never did become fully developed, whilst the Macs, the Camerons, and the Grants, confined to the glens and recesses of their native mountains, subsisted upon oat and barley-meal. While living upon food of that description, the clans were simply marauders, feudal depredators, and plunderers of sheep and cattle, and affected proverbially with contemporaneous distempers. But having been admitted to the Lowlands, and there become partakers of wheaten flour, in the form of fermented bread, the descendants of the Highlanders have been seen endowed with intellect that has rendered them the ornaments of the world, and the boast of literature. Gentlemen, it will be found that the intellect of man is developed exactly in proportion to the consumption of grain for food, and that of all nations, those by whom wheat is consumed, and in the form of fermented bread, are the most distinguished for advancement in civilisation. Hence a distinct gradation takes place in man, from the grain eaters to those who feed on roots. The Hindoos, and other Asiatics, by whom rice and unfermented bread of wheat, barley, and other grains, is consumed, reach a certain stage in civilisation, beyond which they are observed incapable of progressing. On the other hand, the feeders on roots, such as the inhabitants of New Guinea and the aborigines of New Holland, are an unvaried race of wretched savages. Some years ago an Irish sailor was discovered on the desolate shores of an island in the Pacific Ocean; he had subsisted on shell-fish and roots for nearly two years, and had become reduced in that time to the miserable state of a perfect savage. It is consequently a mistake to assert that savagism is the original condition of man. So far from this being the fact, that humiliated state of society clearly exhibits a condition into which man has sunk, in consequence of the neglect of agriculture, and the substitution of roots instead of grain for food. Might not, gentlemen, this fact of a peculiar disposition, derived from vegetable roots, when exclusively used for food, account for much of what passes in a neighbouring island? And might not the encouragement of agriculture, and the cultivation of wheat instead of potatoes, tend more than any legislative enactment, to accomplish the amelioration of the condition of the poor, and diminish the sanguinary excesses which so lamentably prevail in the country to which I allude.

This is, then, gentlemen, the principle upon which the new nosology, I have ventured to submit to you this evening, is founded. In all cases of typhus, small-pox, and plague, the disease originates in a vegetable principle, imbibed either from solid or liquid food, circulating in

the system, and incapable of assimilation with the animal fluids. Hence the worst cases of plague and cholera are identical. This is demonstrated by means of facts contained in the works of Dr. Mead, as contrasted with the account of a case, described by Dr. Mellis, Surgeon of Kishenagut in Bengal. By the latter the instance of a man, affected with cholera, is published in the Calcutta Magazine for the month of November, 1818, in which, upon dissection, gangrene was found existing to a great extent in the intestinal canal. This man died within twenty-four hours from the commencement of the attack: and by Mead it is mentioned, that the worst cases of plague were those in which gangrene in the bowels supervened within twenty-four hours from the first stroke of the disease. Here, then, the cholera of India and the plague, as described by Dr. Mead, are proved to be identical, and consequently both depend upon the same cause, vitiated grain; that being the fact, I hesitate not for a moment to believe, that this subject will be deemed deserving of serious notice from the Medico-Botanical Society. Contagion is at once the bane of mankind and the opprobrium of medicine: and dreadful is it to know, that brave soldiers and sailors, who have been fighting the battles of their country, upon their return to Britain, overwhelmed with disease contracted in the course of service, should, through the operations of the quarantine laws, be excluded from treading the Christian shores of the British empire, lest they should disseminate a distemper, whose origin is wholly dependent upon a cause totally different from contagion, and which malady is liable to be augmented, in all its horrors, by the operation of the very laws that are formed under the mistaken idea, that they tend to its destruction. The importance of the subject upon which I have touched is undeniable; and I conclude with requesting to be allowed to remark, that the absurd vanity of being deemed the author of a new system is far from constituting the motive that has led me thus to trespass upon the notice of the Society. A positive conviction of the utter baselessness of the doctrine of contagion, and the truth of the origin of some of the most terrible diseases to which our race is liable, as propounded by myself, in the pamphlet submitted to your notice, have alone induced me to occupy the time, and intrude on the attention, of the Society, with an attempt at the classification of *morbi Cereales*, or those diseases which are produced by the employment of vitiated grain.

Foreign Medicine.

On the Nerves and Structure of the Iris.

BY M. FARIO, OF VENICE.

SOME anatomists and physiologists attribute to the iris two nervous branches of different

origin, one coming from the third, the other from the fifth pair,—the first presiding over contraction of the pupil, the second over dilatation. The author objects to this hypothesis, on the grounds that the nerves of the iris do not really belong to either of those cerebral nerves, but that they are derived from the ophthalmic ganglion, which certainly receives filaments from those nerves, but constitutes in itself an intermediate centre, where the properties they possessed disappear. These nerves of the iris arise by a common origin from this ganglion, and their antagonist cannot be proved by the experiments instituted in support of that opinion. In some animals these nerves come directly from the cerebral nerves, in which case the movements of the iris seem to be voluntary. Mr. Mayo, having seen the pupil dilate, after the section of the third pair, has thence concluded, that this nerve presides over the contractile motions of the iris; but such an effect might be purely sympathetic with the paralysis of most of the muscles of the eye, brought on by section of the third pair; at all events, we may but conclude, that the ophthalmic ganglion was paralysed in its functions. M. Magendie affirms that section of the fifth pair in rabbits determines a contraction of the pupil, although he thinks that in these animals the fifth pair of nerves sends no branches to the iris. If it were so, what fact would be proved by the experiment? He has been led into error, by supposing that the iris of rabbits receives no branch from the fifth pair; and his experiments are completely at variance with those of M. Fario. The theory of the former being supported by another hypothesis, viz.—that the iris consists of two orders of muscular fibres, one circular, the other radiated, would always be invalidated by the anatomical fact, that no muscular fibres have as yet been demonstrated in the iris. On the contrary, the vascular, spongy, and erectile structure of this membrane, demonstrated by simple inspection and by the microscope, is confirmed by its relations to the choroid. The iris relaxes and enlarges the pupil when the choroid is inflamed; because then the vessels of the latter, being congested, no longer send to the iris a sufficient quantity of blood to render it turgid. However that may be, the following are the principal experiments attempted by the author, the results

of which are curious. He took off the cranium in a young pigeon, divided the membranes, and raised the anterior lobe of the cerebrum, which operation apparently gave excessive pain to the animal and caused slight contraction of the pupil. The trunk of the third pair was then divided, the pupil did not immediately dilate, but in the course of eight minutes; ten minutes after, the fifth, and again, at a similar interval, the optic was cut through; the dilatation did not increase, but, however, the animal was apparently overcome. On another pigeon, section of the ophthalmic nerve, dilatation of the pupil; five minutes after division of the third pair, dilatation increased; and in another five minutes after section of the optic nerve, the pupils became dilated to its greatest degree. On a third pigeon, section of the optic nerve was succeeded by dilatation, which was not augmented by the subsequent section of the third and fifth. When the optic nerve of one eye is divided, the pupil on the opposite side is dilated, which does not happen after section of the third and fifth. Finally, in another pigeon, the right eye was experimented on, and the iris pricked, so as to produce a permanent contraction of the pupil, which was increased by the incisions practised to expose the nerves. Division of the fifth, then, produced no effect: that of the third caused some increase of the dilatation; but the bird died before the experiments could be carried any further. This was repeated on another pigeon, but the third pair was first divided, and produced slight dilatation; division of the fifth increased it a little; and that of the optic nerve made it still more sensitive; but the bird died. The same experiments were tried on rabbits and cats, but their results were neither as marked nor as constant. Section of the optic nerve was always followed by sensible dilatation. As for the contraction of the pupil after division of any of these nerves, it was never noticed in any of these experiments; much more, in one rabbit the author multiplied the irritation of the nerves, especially of the fifth pair, touched them with vinegar, and even with solution of caustic, without giving rise to contraction of the pupil, although this phenomenon was noticed as soon as the iris was pricked through the cornea with a cataract needle. The author allows that many

objections may be made to his experiments, but they are such as to be common with all experiments of the same nature. The uniform result of his trials says much in their favour; and we may, at all events, conclude from them, that there is no sort of antagonism between the different nerves of the iris.

*Encysted Ovarian Dropsy of the right side
—Supposed extra-uterine Pregnancy—
Cæsarean operation—Death.*

BY M. BRICHETEAU.

A woman, 47 years of age, who had long been married, but had no children, came into Hôpital Necker in the month of June. There had been suppression of the catamenia for nine months, and she stated that, at the time of her supposed conception, a violent quarrel had arisen between her and her husband. On her admission the abdomen was prominent, she experienced those pains which are the usual forerunners of parturition. A tumour in the loins on one side could be distinctly felt, resembling in its form the head of a child, in the opposite side, a prominence which could easily be imagined to correspond to the foot of the foetus; the tumour could readily be displaced by pressure. The patient pretended that she could discern in her abdomen the motions of the child; there was also a *bruit*, which was attributed to the action of the placenta. On the first examination per vaginam, the neck of the uterus could not be detected; on the second trial, made the next day by M. Baudelocque, the os uteri was felt under the pubes in a contracted state; on a third examination which was made by the rectum and vagina at the same time, a fluctuating tumour was detected, which could be readily displaced by the finger, and was manifestly connected with that in the abdomen.

The pressure caused by the tumour rendered the use of the catheter necessary; the patient suffered severely, but at intervals, as in labour; she had no fever, nor was her skin hotter than natural. Whenever the abdomen was compressed, the pains assumed an expulsive character, and the woman exhausted herself in vain with repeated efforts. This state of things became more and more aggravated, notwithstanding the employment of the warm baths, fomentations to the abdomen, and blood-

letting. The unfortunate creature could obtain no rest, and her sufferings were so excessive, that she requested an operation might be performed to extract the child she supposed was in the uterus. The state of the tumour was again examined by the medical officers of the hospital; it was generally supposed that the patient had an extra-uterine pregnancy in the right ovary, and that the only chance of relief could be afforded by opening the cyst, which was supposed to contain it. The surgeons consulted for some time together, as to what would be the most proper mode of treatment, if no relief was afforded to the tortures of the patient; they all agreed, that an incision into the vagina, for the purpose of exploring the contents of the tumour, was the only course likely to relieve the symptoms. The absence of peritonitis was thought to encourage this proceeding. At 3, P.M., on the 6th of July, M. Langier, in presence of several surgeons and a great many pupils, after a careful re-examination of the state of the patient, made a slight incision in the posterior wall of the vagina, which did not appear to cause much pain, but was followed by the discharge of about a pint of clear bloody serum; the index finger being introduced into the wound, a cyst was discovered, but no foetus could be found. The patient was carried to bed, and fomentations were kept continually applied to the belly; fever diet alone was allowed. The next day she was much relieved; there was but slight pain in the belly; pulse frequent; skin cool. On the 8th symptoms remained the same, but the pulse had increased to 112 in a minute; both the retention of urine, and the *bruit* returned as before the operation; the patient could only lie on her back, decubitus on the side, bringing on anxiety with severe pain. The abdomen, however, was not at all pained by pressure. Fifteen leeches were applied to the perinæum, and emollient fomentations continued. (Gum water and fever diet.)

9th. Face anxious; pulse more frequent; melancholy forebodings, and continued shudders.

10th. During the night symptoms of peritonitis supervened; twenty leeches were applied to the abdomen, which was so painful as not to bear the slightest pressure.

11th. Great depression; pulse extremely

small; respiration hurried, and in the course of the night she died.

Autopsy.—The abdominal tumour was found to have descended in the pelvis, coagulable lymph had been effused about the inferior surface of the peritoneum; there was serum effused in its cavity, and the convolutions of the intestines were glued together by false membranes. The tumour was uneven; and appeared to be composed of several lobes; on the left side it was pyriform and bore some resemblance to an enlarged uterus; it proved to be this organ itself, in the cavity of which a structure of a lardaceous nature, in size like a large pear, had developed itself; it was entirely covered by the uterus, which had, as it were, expanded into a thin lamina to cover its contents. It communicated with the vagina and with the cervix uteri, the latter being so thin as to leave only a small membranous opening of about two lines in diameter. The right portion of the tumour was composed of several lobes, uneven and ulcerated on its surface, which was here and there covered by loose portions of membrane. These lobes were formed internally by organic degenerations, such as carcinomatous and encephaloid structures, separated from each other by cellular or puriform septa, or by small cysts filled with a dark and ichorous serum. No traces of the ovary remained, which had probably been destroyed by the pressure of the morbid surrounding structures; perhaps the ovary itself had been the first seat of the disease. At the inferior and back part of the pelvis was another mass, which had compressed the bladder against the arch of the pubes, and driven the rectum and the posterior wall of the vagina upwards and backwards. In this part of the tumour were serous cysts, of two or three inches diameter, in close contact externally with the disorganised mass. It was in one of these cavities that the incision had penetrated; another, a little behind it, had not been opened, but contained a great quantity of limpid serum. These two cysts having been distended by fluid, and pressed upon by the tumour above, had been doubtless the cause of the retention of urine, and the excruciating pains which had been complained of by the patient.

It will be important to notice, says M.

of which are curious. He took off the cranium in a young pigeon, divided the membranes, and raised the anterior lobe of the cerebrum, which operation apparently gave excessive pain to the animal and caused slight contraction of the pupil. The trunk of the third pair was then divided, the pupil did not immediately dilate, but in the course of eight minutes; ten minutes after, the fifth, and again, at a similar interval, the optic was cut through; the dilatation did not increase, but, however, the animal was apparently overcome. On another pigeon, section of the ophthalmic nerve, dilatation of the pupil; five minutes after division of the third pair, dilatation increased; and in another five minutes after section of the optic nerve, the pupils became dilated to its greatest degree. On a third pigeon, section of the optic nerve was succeeded by dilatation, which was not augmented by the subsequent section of the third and fifth. When the optic nerve of one eye is divided, the pupil on the opposite side is dilated, which does not happen after section of the third and fifth. Finally, in another pigeon, the right eye was experimented on, and the iris pricked, so as to produce a permanent contraction of the pupil, which was increased by the incisions practised to expose the nerves. Division of the fifth, then, produced no effect: that of the third caused some increase of the dilatation; but the bird died before the experiments could be carried any further. This was repeated on another pigeon, but the third pair was first divided, and produced slight dilatation; division of the fifth increased it a little; and that of the optic nerve made it still more sensitive; but the bird died. The same experiments were tried on rabbits and cats, but their results were neither as marked nor as constant. Section of the optic nerve was always followed by sensible dilatation. As for the contraction of the pupil after division of any of these nerves, it was never noticed in any of these experiments; much more, in one rabbit the author multiplied the irritation of the nerves, especially of the fifth pair, touched them with vinegar, and even with solution of caustic, without giving rise to contraction of the pupil, although this phenomenon was noticed as soon as the iris was pricked through the cornea with a cataract needle. The author allows that many

objections may be made to his experiments, but they are such as to be common with all experiments of the same nature. The uniform result of his trials says much in their favour; and we may, at all events, conclude from them, that there is no sort of antagonism between the different nerves of the iris.

The absence of peritonitis was thought to encourage this proceeding. At 3, P.M., on the 6th of July, M. Langier, in presence of several surgeons and a great many pupils, after a careful re-examination of the state of the patient, made a slight incision in the posterior wall of the vagina, which did not appear to cause much pain, but was followed by the discharge of about a pint of clear bloody serum; the index finger being introduced into the wound, a cyst was discovered, but no foetus could be found. The patient was carried to bed, and fomentations were kept continually applied to the belly; fever diet alone was allowed. The next day she was much relieved; there was but slight pain in the belly; pulse frequent; skin cool. On the 8th symptoms remained the same, but the pulse had increased to 112 in a minute; both the retention of urine, and the *bruit* returned as before the operation; the patient could only lie on her back, decubitus on the side, bringing on anxiety with severe pain. The abdomen, however, was not at all pained by pressure. Fifteen leeches were applied to the perinæum, and emollient fomentations continued. (Gum water and fever diet.)

9th. Face anxious; pulse more frequent; melancholy forebodings, and continued shudderings.

10th. During the night symptoms of peritonitis supervened; twenty leeches were applied to the abdomen, which was so painful as not to bear the slightest pressure.

11th. Great depression; pulse extremely

small; respiration hurried, and in the course of the night she died.

Autopsy.—The abdominal tumour was found to have descended in the pelvis, coagulable lymph had been effused about the inferior surface of the peritoneum; there was serum effused in its cavity, and the convolutions of the intestines were glued together by false membranes. The tumour was uneven; and appeared to be composed of several lobes; on the left side it was pyriform and bore some resemblance to an enlarged uterus; it proved to be this organ itself, in the cavity of which a structure of a lardaceous nature, in size like a large pear, had developed itself; it was entirely covered by the uterus, which had, as it were, expanded into a thin lamina to cover its contents. It communicated with the vagina and with the cervix uteri, the latter being so thin as to leave only a small membranous opening of about two lines in diameter. The right portion of the tumour was composed of several lobes, uneven and ulcerated on its surface, which was here and there covered by loose portions of membrane. These lobes were formed internally by organic degenerations, such as carcinomatous and encephaloid structures, separated from each other by cellular or puriform septa, or by small cysts filled with a dark and ichorous serum. No traces of the ovary remained, which had probably been destroyed by the pressure of the morbid surrounding structures; perhaps the ovary itself had been the first seat of the disease. At the inferior and back part of the pelvis was another mass, which had compressed the bladder against the arch of the pubes, and driven the rectum and the posterior wall of the vagina upwards and backwards. In this part of the tumour were serous cysts, of two or three inches diameter, in close contact externally with the disorganised mass. It was in one of these cavities that the incision had penetrated; another, a little behind it, had not been opened, but contained a great quantity of limpid serum. These two cysts having been distended by fluid, and pressed upon by the tumour above, had been doubtless the cause of the retention of urine, and the excruciating pains which had been complained of by the patient.

It will be important to notice, says M.

Richetagn, that the peritonitis was confined to the external surface of the intestines, that it did not penetrate into the cellular tissue at the lower part of the pelvis, and that the wound made by the incision was beginning to cicatrize. From this it is evident that the peritonitis was not brought on by the operation, and that, notwithstanding the absence of prominent symptoms, the inflammation had previously existed, and was the cause of the dreadful pain; nor can it be said that the operation hastened the death of the unfortunate woman, for she was relieved for two or three days from sufferings so intolerable as to threaten dissolution. Had no peritonitis supervened, and only one cyst been present, a cure might have been expected, and even if there had been an extra-uterine foetus, as seemed very probable, we might have hoped for such a result. The operation, though doubtful, was certainly preferable to an inevitable death. The other signs of pregnancy, coupled with the false placental bruit, which was probably owing to a compression of the aorta by the tumour, had led to the supposition of an extra-uterine pregnancy. The latter symptom, which is generally considered to be one of the most certain, is thus proved to be sometimes fallacious.

[Professor Montgomery and Dr. Kennedy of Dublin, have noticed the various positions which may cause the bruit de soufflet independent of pregnancy.—*Cyclopædia of Medicine, Obstetric Auscultation, &c.*—Eds.]

Reviews.

The Effects of Minute Doses of Mercury.

By A. P. PHILIP, M.D., F.R.S., &c. 12mo. 1854. H. Reushaw.

ON a former occasion we expressed our favourable opinion of this little work, but after a re-perusal of it, we feel so convinced of its value, that we should not do justice to our readers were we not to give them such a specimen of the author's conclusions, as will enable them to judge for themselves. Moreover, there is no medicine so much used as mercury, and none whose mode of action is so little understood. Dr. Philip attests our opinion.

"It is now nearly thirty years since I first began to employ minute and frequently-re-

peated doses of mercury. I was led to them by observing that, in lessening the dose and increasing its frequency, in proportion as we lessen the immediate, we increase the alternative, effects. It had long been my wish to lay before the profession the whole of the circumstances which influence this practice; but these are so numerous, and some of them, from the nature of disease, so complicated, that I found it difficult to arrange the subject in a way that would give to others a clear and full view of it, and was thus till lately deterred from the attempt.

"Having, in the early part of this practice, met with a few fortunate cases, I imagined that it was difficult to assign limits to its beneficial effects in certain description of diseases. By degrees, however, these limits became apparent, but they have left a field more than sufficient to compensate for the pains I have bestowed on the subject. I have found, that with an attention to the circumstances which I am about to state, the minute doses never do harm; and this I believe, under any circumstances, cannot be said of any other mode of exhibiting mercury; and that in a wide range of cases, both original and sympathetic, they effect what cannot be effected by any other means with which we are acquainted. It is particularly grateful to my feelings that I have now obtained the testimony of many of my professional brethren, to confirm my belief that they have been the means of restoring many who could not otherwise have been restored.

"Large doses of mercury cannot be repeated at short intervals without often rendering the remedy as pernicious as the disease, and sometimes more so; and when they are given at distant intervals, the effect of one dose is frequently lost before another is taken; so that it often happens that little or no progress is made in the cure; and there is nothing but temporary relief to compensate for the debilitating effects of each dose; while, with respect to the minute doses, although each does little, this little it does without any strain to the constitution, and the next dose comes before the effect is lost; so that a gradual accumulation of the beneficial effect is obtained, and that, if the circumstances I am about to point out be attended to, without any injurious effects to deduct from it. The part affected is thus gra-

dually solicited to resume its functions, and, though slowly, at length effectually restored.

“ There is no other medicine which has been, and still with many is, the subject of such strong prepossessions as mercury. Some, confining their attention too much to the beneficial effects resulting from it, and which it was found could not otherwise be obtained, were led to an incautious use of it; and thus it naturally happened that others, struck with the mischief it occasionally did in the hands of its admirers, had their attention as exclusively directed to its injurious effects; for, from the nature of things, all medicines capable of much good are also necessarily capable of much evil. Which of our most valuable medicines is not poisonous in larger doses?

“ The public, which, possessed as it is of a thousand eyes and ears, seldom remains long in error, has decided between these opponents; and no other medicine, in those countries where the practice of medicine is best understood, is now in such general employment. It therefore only remains for us to inquire how we can most effectually secure the advantages and avoid the injurious effects of so active a remedy.

“ One of the chief means, we shall find, is lessening the quantity employed, which, as far as I am capable of judging, has in this country been at least ten times that from which its most beneficial employment results. The others are numerous. All who are accustomed to reflect on the endless variety of disease, the various circumstances in which we are placed, the difference of constitution in different individuals, and the power of habit in all, will perceive that the most beneficial employment of such a medicine is a question of a very complicated nature, and one relating not to it alone, but to all others, which, given in combination with it, tend either to improve its beneficial, or correct its injurious, tendencies.

“ It is remarkable that, notwithstanding the general and long-continued employment of mercury, it should not have been known that all its constitutional effects, not excepting complete salivation, may generally be obtained by such doses as half or even the third part of a grain of blue-pill taken three times a day: that is a dose only equal to the twentieth or thirtieth part of a grain of calomel; for a grain of calomel is equal, whether we regard

its purgative, or, when divided into minute parts, its alterative, effects, to ten grains of blue-pill. If such be the case, what should induce us to employ larger quantities, except the disease requires a more rapid effect than can be obtained from such doses, or, from some peculiarity in it or the habit of the patient, the sensibility to their effects is impaired? No other person, as far as I know, has been led to the use of these doses of mercury, which, I think it will be admitted from the facts I am about to state, constitute, in a great variety of cases, its most beneficial employment.

“ To chronic disease the minute doses are peculiarly adapted. A disease which has become habitual, can only be counteracted by a remedy which, without injury, may be rendered habitual also; and in acute diseases, although they are not sufficiently active to effect the cure, we shall find them, in many cases, essentially aiding the more active, and consequently injurious means, and enabling us to lessen both their extent and continuance.”

Our author next describes the sympathetic effects of mercury, and then proceeds to give his opinion of its mode of operation; which every medical practitioner must peruse with interest. The description is graphical, and cannot be abridged with justice to our readers or the author. It is as follows:—

“ *Of the Modus Operandi of Mercury.*— It appears, from every thing we know of the effects of mercury, and the laws of the living animal body, that it acts in two ways. It has a local and general operation, and its general operation is of two kinds. Like all other substances capable of affecting the living animal, it at the same time operates on the part to which it is applied, and on the system in general through the nerves of that part. But, as it is one of those medicines which are capable of being absorbed, it also influences the whole habit, by circulating with the blood, and thus directly acting on the various organs, by its immediate application to them; and although, as we might have foreseen from the laws of the animal economy, it is capable, by its action on the part to which it is applied, of affecting every other part, the nervous system forming the living animal body into a whole, which cannot be impressed in any one

part without all others, more or less, feeling the impression, it is in consequence of its absorption, that it most effectually influences distant parts. Its operation is, more or less, that of a stimulant; for, according as circumstances direct it to particular organs, we find it exciting them to an increased performance of their functions. While it retains the active form in which it is introduced, it seems incapable of remaining in the system. If it be prevented from running off by one excretory, it finds its way by another; thus we see it exciting the skin, kidneys, salivary glands, &c. Like all other metals, in its metallic and insoluble form, it is inert. In the state of quicksilver it may be freely drank without any inconvenience but that which is occasioned by its weight; and it can only remain in the system when deposited in the cellular substance in that form, to which it is reduced by the chemical powers of the constitution; for in whatever state it is given, these powers always reduce it to its original metallic form. It is well known that gold and silver are amalgamated with mercury, if worn by a person whose system is impregnated with it.

“When taken internally it is doubly applied to the stomach and bowels, immediately, and through the medium of the circulation, for we often have to contend with its irritating effects on the alimentary canal, when it is only introduced by the skin. In this canal and the salivary glands alone, its passage excites sensible irritation, which, if considerable, causes inflammation; in the former only superficial, and generally in a slight degree, but in the latter often such as to affect all the neighbouring parts.

“In both cases, as it generally increases the natural secretion of the parts affected, the increased discharge, like all other discharges, tends to relieve the inflammatory action; it is where the discharge is least—that is, where there is some impediment to the free operation of the mercury in increasing the secretion from the part—that the inflammatory tendency is greatest.

“Such are the more prominent effects of mercury introduced into the system; but I have, in my *Inquiry into the Laws of the Vital Functions*, been at much pains to point out that there is no agent capable of affecting the living animal body that does not possess

both a stimulant and sedative power with respect to it, according to the degree in which it is applied, and the state of the body at the time of its application; the stimulant arising from the less, the sedative from the greater, application of it; and that the degree in which agents possess the stimulant and sedative power, although in the same agent always in the same proportion to each other, is, in different agents, in no determinate, but every possible, proportion. Thus, spirit of wine possesses a great degree of stimulant, compared with its sedative tendency, which only appears when it is taken in excess; while tobacco possesses a great degree of the sedative, and little stimulant tendency, which appears only when it is applied in very minute quantity.

“The sedative effect of some agents, as of opium, is chiefly exerted on the sensibility; of others, as tobacco, on the moving powers of the animal system. While the influence of the former, therefore, may be salutary, that of the latter, except under very peculiar circumstances, is always pernicious.

“There may be some objection to using the term sedative for agents of both descriptions. In this sense, however, it is used by writers, although not constantly, but I think it is better thus to employ it than to introduce a new term, as after this explanation no ambiguity can arise from it. Besides, as both act by diminishing the vital powers, it is convenient that there should be an appellation common to both; and what I am about to say will be sufficiently distinct, without a term to designate either alone. By sedative, then, I mean whatever depresses the powers of the system, whether sensitive or motive, and whether it affects both or either, although the more common use of the term confines it to the agents which impair the sensibility.

“No agent can impair the sensitive without more or less impairing the motive powers, because the latter in many instances depend on the former: but it is very possible to impair the motive without causing any diminution of the sensitive powers, and even with the effect of a morbid increase in them, because the derangements which accompany the weakened power of life often prove to the sensitive powers a fruitful source of irritation. Thus, that class of sedatives whose operation

as on the motive powers alone, are often doubly pernicious.

“Mercury, like other agents, possesses the sedative as well as the stimulant property; and its sedative property appears to be wholly exerted on the motive powers—for when it appears to lessen the sensibility, this effect seems to arise merely from its removing some cause of irritation. Its sedative tendency is very different in different constitutions; and in some it exists to a degree that wholly precludes its employment. The sedative effects of mercury, then, as of all other medicines possessing similar properties, are known by its producing a state of debility, with or without more or less nervous irritation, according to the circumstances of the particular case.

“Thus the injurious effects of mercury may be divided into two classes—those which arise from an excess of its stimulant, and those which depend on its sedative effect. By the former it may cause all the evils of extreme irritation; by the latter it tends more directly to impair the powers of life; and these effects admit of every degree, from that of a very mild to that of the most destructive agent, according to the quantity employed, the form in which it is given, the nature of the disease, and the state of the particular constitution.

“Let us now consider what are the virtues of this medicine, which, notwithstanding its injurious tendencies, still render its use in this country more general than that of any other; for it would be absurd to suppose that it had obtained this general employment, without possessing some extraordinary beneficial powers to compensate for its evil tendencies.

“It will readily be supposed that a medicine, possessed of so great a power of exciting the various secreting surfaces, must prove a means of relief to many states of disease, especially those attended with a general failure of power in these surfaces. To this effect, for example, we are in a great degree to ascribe its beneficial operation in fever, particularly when it excites the bowels, or is determined to the skin, the most extensive of all the secreting surfaces; and in the various forms of dropsy, and other cases connected with failure of power in the extreme vessels.

“In most instances, however, the failure in secreting surfaces is but the secondary part of

the disease, depending on some more partial and specific derangement. If, therefore, the beneficial effects of mercury were confined to its influence on the secreting surfaces, the relief afforded by it would in most cases be imperfect and temporary; and this is often the case, when the original derangement is of a nature which it cannot influence.

“But we find in many such cases, that it is often capable of permanent relief; it must, therefore, possess some beneficial tendency besides that of a mere stimulant to those surfaces. It is necessary, therefore, in order to understand the nature of the extensive influence of mercury in the cure of disease, to look for some other principle of action; and in the peculiar effects of this medicine, compared with the well-established laws of our frame, we shall find such a principle.

“Although all substances capable of affecting the living animal act as stimulant or sedative, according to the degree in which they are applied, yet there is in the effect of each something peculiar to itself. Thus we have just seen that the proportion in which they possess the stimulant and sedative powers is different in different agents, and that the latter in some agents is chiefly exerted on the sensitive—in others, on the motive powers. These are differences easily observed and readily classified. But there is an infinite variety both in the stimulant and sedative effects of different agents, which, from their number and indistinctness, cannot be reduced to any general principle of classification; and physicians have attempted nothing further than to divide medicines into those best suited to influence the state of different organs. Thus we speak of aperients, expectorants, diaphoretics, diuretics, &c. and we have no means of knowing the peculiar properties of each particular agent, but by observing the effects it produces.

“The most remarkable of the effects peculiar to mercury, is its influence on the liver. It is not surprising that a medicine which so powerfully influences the secreting organs in general, should influence the secreting power of this organ; but, independently of this effect, it has a specific operation on the liver, a power not merely of exciting its functions, but of correcting the various derangements of that function in a way which it does not possess with respect to any other organ, and which no

other medicine possesses with respect to the liver; and that even to such a degree as not only to restore a healthy state of the bile in various deviations of this fluid, but often even to correct the most formidable change of structure in the organ which secretes it.

"In my Treatise on Indigestion, I have had occasion to point out at length the intimate sympathy which exists between the stomach, liver, and that intestine, which immediately receives the food from the stomach, and where it is mixed with the bile and pancreatic juice, the three chief digestive organs, which so constantly partake of the affections of each other, that all are injured or relieved by causes affecting any one. Thus mercury, possessing no particular power of relieving the affections of the stomach or duodenum, and even ungrateful to both, often becomes indirectly the best means of relieving their derangements, so often caused or supported by a disordered action of the liver.

"When, therefore, we consider that the sympathies of the digestive organs are more extensive than any other, so that there is hardly any disease of which they do not partake, and whose course is not influenced by them; we are at no loss to find one cause of the extensive effects of the medicine which so essentially controls them.

"But a principal cause of this extensive sympathy of the digestive organs is the peculiar sympathy of the liver itself with the chief source of nervous power,—the brain; in consequence of which all the affections of the one are immediately felt by the other. However severe inflammation of the stomach and bowels, the intellects remain unaffected. I have seen it prove fatal within twenty-four hours, the mind remaining entire to the last; while acute inflammation of the liver is generally attended with delirium. Melancholy even takes its name from a morbid state of the bile; and severe blows on the head are more apt to excite inflammation of the liver than of the other thoracic and abdominal organs.

"When it was supposed that the office of the brain was chiefly confined to the mental functions, and that its principal relation to other parts was that of bestowing sensibility on them—when it was supposed incapable of directly influencing either the heart or blood-vessels, on which the vital powers so evidently

depend—we had a very inadequate idea of the importance of this organ in the animal economy; but when we know that it is not only capable of directly influencing the action of the heart and blood-vessels, and that to their minutest ramifications in every part of the system, and that the secreting and other assimilating processes are not merely influenced by, but wholly dependent on it and the spinal marrow, we can easily understand how its affections control all the functions of life; and can feel no surprise that whatever essentially influences it, should also extensively influence the phenomena of disease.

"These are fruitful sources of the influence of the liver in diseased states of the system; but even these are not its only sources. All other parts receive their blood directly from the heart; it receives the principal part of its blood from the other abdominal viscera. It is thus also, as well as by its sympathy with the brain, intimately connected with the whole tract of the alimentary canal, the internal surface of the body, and through it, in consequence of the intimate sympathy which exists between it and the external surface, with this surface also. No affection of either can take place, without more or less affecting it through both the nervous and sanguiferous systems; and by the state of these surfaces, more than any other cause, the phenomena both of health and disease are influenced. The great extent of the liver is also to be ranked among the causes which contribute to its influence in the animal economy, in consequence of which, whatever influences the distribution of the blood in it, more or less influences its distribution in every other part. Such are the conclusions respecting the influence of the liver, to which we should, *a priori*, be led by a knowledge of the structure and functions of our frame, and they are amply confirmed by direct observation.

"All who have had extensive opportunities of observing the phenomena of disease, must be struck with the manner in which the state of the liver influences, and is influenced by them, to whatever class they belong. It is unusual in any formidable disease, whether general or local, not to find the function of the liver more or less disturbed; and wherever it is influenced, the proper treatment of the disease more or less depends on the state

of this organ. It is by no means uncommon to find diseases, particularly of the vital organs, intractable till the accompanying derangement of the liver has been observed and corrected; and I have often in such cases seen, not only the patient, but the medical attendant, surprised at the immediate relief thus obtained:

"When, for example, inflammatory affections of the chest have been but imperfectly relieved by the usual means, and have constantly continued to recur; or the patient has laboured under an obstinate though languid fever, with confusion of mind, and sometimes a low muttering delirium, a fulness and tenderness in the region of the liver have been discovered; on relieving which, by the usual means, the whole of the symptoms have immediately and permanently yielded.

"Thus it is that in warm climates, where the sympathies of our frame are most active, not only in all febrile diseases, but even in all chronic deviations of health, affections of the liver become the leading feature.

"I have for many years past, in every case, whether acute or chronic, been in the habit of examining the region of the stomach and liver as regularly as that of the pulse; and I think all, who will take the trouble to do so, will confess that the one examination is often of as much importance as the other, and in many cases the former the most important of the two.

"It is the sympathy of the liver with the general source of nervous power, and the other circumstances relating to this organ which have been enumerated, that, even more than the sympathies of the digestive organs in general, gives to the medicine, that so powerfully controls it, its extensive influence in the cure of diseases.

"Such I conceive to be the causes which have rendered the employment of mercury so general in the practice of this country; which, resting on more extended as well as more accurate principles, it is not assuming too much to say, is more effective than that of perhaps any other.

"If the state of the liver be so extensively connected with that of all other parts of the system, and, in particular, so powerfully influence the other digestive organs, with all their extensive sympathies; is it surprising that a medicine, which has so great a power

in controlling the affections of this organ, should hold a chief place amongst the means of cure; and that in the country where the practice of medicine is best understood, it should be found in the most general employment?

It will be admitted, from all that has been laid before the reader, that, to say nothing of its effects in the disease for which it was first introduced, the treatment of which chiefly belongs to the surgeon, it is well worth while to inquire into the best mode of employing so essential and powerful a means; and this is the more necessary, because, like other means, capable of great good, it is also capable of great injury. Its beneficial effects have naturally led to too incautious a use of it; by which much mischief has been done, and the remedy itself, with those who either lack opportunities or correct powers of observation, brought into discredit.

"The result of my own experience (and there are few whose attention has been more directed to the subject) is, that, although there are many circumstances under which large doses of mercury are not only beneficial but essential, the quantity, as I have already had occasion to state, employed in this country, has on the whole been at least ten times greater than that from which its most beneficial effects would accrue. It unluckily happens, that, in a large proportion of cases, its most beneficial employment is not always that which produces the most immediate benefit; and in grasping at too much, we often not only lose the advantage of the remedy, but convert it into a source of injury.

"It is a law of its action, that, when it is directed to one outlet, it is less inclined to pass by others; thus, when it is passing off rapidly by the skin, which is known by the scarcity of urine,—if, in consequence of taking cold, or an increased quantity of the medicine, it is thrown on the salivary glands, the usual secretion of urine is restored, indicating that it is no longer powerfully exciting the skin; or perhaps increased, for the salivary glands affording but a narrow outlet, it still in part tends to pass by other channels. It seems to be on this principle, that salivation renders it more powerful with respect to the disease, and particularly that diuretics which did not previously excite the kidneys, now

have this effect; but mercury seldom produces salivation unless the system be highly impregnated with it, and then—to say nothing of the irritation occasioned by the salivation itself, which is often great—its sedative effect is frequently much felt, and the whole powers of the constitution are, for the time, enfeebled by it.

“It was a maxim of the older practitioners, that its beneficial effects are proportioned to the degree of salivation it excites; and I have heard the late Dr. Monro, of Edinburgh, state the quantity of saliva which must be discharged daily, in order to eradicate particular affections. Can we be surprised that, when such maxims reigned, the remedy proved sometimes worse than the disease, and that so strong a prepossession against it has arisen?”

“I have said that before salivation takes place, the system is generally much impregnated with the medicine, for this is not always the case. In particular constitutions the smallest dose immediately affects the salivary glands. Thus, in general, although we find mercury most effectual when it produces salivation, in some habits this occurs so readily, as wholly to preclude its employment, and consequently to render it useless as a remedy. In others the same consequence ensues from the sedative effect, immediately arising from such minute doses, that, from this cause also, its injurious effects alone are attainable.”

The succeeding chapter is on the *modus operandi* of minute and frequently-repeated doses of mercury, which is extremely interesting. But, as our limits will not allow us to copy it, we feel convinced that our practical friends will possess themselves of the original.

Pharmacopœia Homœopathica. Edidit à
F. F. QUIN, M.D., &c., &c. 1834. Lon-
dini: Veneunt S. Highley.

We have now before us the most extraordinary book of this age of intellect and reason; and, were its contents entitled to the slightest credit, our druggists, chemists, and apothecaries might abandon their avocations, inasmuch as the whole *Materia Medica*, according to this incomparable system of therapeutics, may be conveniently carried in the waistcoat pocket. A grain of magnesia or jalap is sufficient to

cure a multitude—a standing army; and as to a grain of calomel, it is more than sufficient to mercurialise all Europe! Nevertheless, the parties practising this system are acquiring more fame and wealth than any physician or surgeon in London at the present moment. Long may they enjoy their reputation, say we, and diffuse the blessings of homœopathy, or, as an inveterate hypochondriac who was cured by it, after travelling through Europe, modestly terms it, the “gospel of medical salvation.” Chemistry and pharmacy are no longer necessary, for all medicines are to be prepared by the addition of spirit of wine and sugar of milk. The composition of all medicines are termed attenuations. The first formula is one grain or drop attenuated with one hundred grains of sugar or drops of milk or spirit of wine, one drop or grain of which is again mixed with the above quantity, and so on for thirty times; and every grain of each admixture is a most powerful medicine.

These medicines are classed as follows:—

- | | |
|-----------------------------|------------------|
| 1. Prima attenuatio | Centesima pars |
| 2. Secunda . . . | Decies millesima |
| I. Tertia . . . | Millionesima |
| II. Sexta . . . | Billionesima |
| III. Nona . . . | Trillionsima |
| IV. Duodecima . . . | Quadrillionsima |
| V. Decima quinta . . . | Quintillionsima |
| VI. Duodevigesima . . . | Sextillionsima |
| VII. Vigesima prima . . . | Septillionsima |
| VIII. Vigesima quarta . . . | Octillionsima |
| IX. Vigesima septima . . . | Nonillionsima |
| X. Trigesima . . . | Decillionsima |

Many of our junior readers may not clearly estimate the minuteness of the doses of this division. We must, therefore, remind them of the first principles of notation. Every one is aware of the terms tens of thousands and hundreds of thousands. The fourth place of a number is called the place of thousands (that is, any number of thousands under ten thousand), the fifth place is tens of thousands the sixth hundreds of thousands, the seventh millions (a million being ten hundred thousand), the eighth place tens of millions, the ninth place hundreds of millions, the tenth place thousands of millions, the eleventh place tens of thousands of millions, the twelfth place hundreds of thousands of millions, and in this order we may conceive places to be continued infinitely from the right hand towards the

left, each following place being ten times the value of the next preceding.

When it is required to write down more places than twelve, the period is called billions, the sixth thousands of billions, the seventh trillions, the eighth thousands of trillions, the ninth quadrillions, &c. Now we request our readers only to bear in mind, that the homoeopaths are not content with the hundred thousand millionth part of a grain of any medicine as a dose, but they advise a thousand billionth, a trillionth, a quadrillionth, and so on nearly to an inappreciable proportion. Notwithstanding the obvious and unparalleled absurdity of this mode of dosing medicines, we have two medical men adopting the system, and a vast number of hypochondriacs proclaiming their miraculous cures by this plan of treatment. These are, of course, ordered to live regularly, and avoid every moral and physical cause of disorder, and then the trillionth of a grain of blue pill, taken night and morning, effects their cure.

There is another advantage in this system, that the prescriber supplies the remedies, and that these are so minute, that a month's medicine may be inclosed in a single letter to the country. Of all the gross kinds of empiricism this is the greatest,—it surpasses animal and metallic magnetism, metallic tractors, celestial beds, the rubbing system of St. John Long, and the puffs of the most notorious and unprincipled quacks that infest this country. Nevertheless, it is patronised as a novelty by the upper classes, and its practitioners, who are only two in this metropolis, are making a golden harvest; and one of them was so much engaged, that he could only take an hour's sleep during a week, so occupied was he in answering letters and furnishing his medicines by return of post. We shall dwell no longer on this humbug system of quackery, but leave our readers to form their own opinions on the subject.

MEDICAL SOCIETY IN THE WEST RIDING OF THE COUNTY OF CORK.

ABOUT five years since a medical society was formed in the West Riding of the county of Cork, by the practitioners in that district, and the members since its establishment have had several important meetings, as well for the

discussion of professional subjects, as the keeping up a friendly intercourse. The rules of the Society are now before us, and appear to be based on liberal principles. The first meeting of the Society for the present year was held in Bandon, on the 6th inst., and the subjects submitted for discussion were, the Origin and Progress of Sarcomatous Tumour, of which a preparation was exhibited, and an exceedingly interesting case of Metastasis of Hæmorrhage, the details of which we hope to be put in possession of. The members of the Society have it in contemplation to publish a periodical (quarterly) for the province of Munster. We wish them success in their undertaking, and shall, when their embryo journal appears, be happy to give our candid opinion on its merits. We wish such societies were general throughout Ireland, as we are convinced they must tend to the benefit both of the profession and of the public.

PRIZES TO MEDICAL STUDENTS.

WE have given in another part of this number an account of the successful candidates for the prizes bestowed by the St. Bartholomew Medical School. We are aware such prizes generally have been subject of comment elsewhere, and have been discouraged as an artifice for practising deception upon the public. It may be that the system of bestowing rewards at a particular school is bad,—that the pupil, who is rewarded as the best in a small class, may possess very little absolute merit,—and may, perhaps, be chosen by his teachers, if they are the examiners, from motives of partiality; and the suspicion of favouritism will always exist where the teachers dispense the rewards. All these allegations and suspicions may be well founded; but as we hold that emulation is the main spring operating upon a youthful and generous mind, we

conceive such a stirring motive to exertion should be introduced into the study of medicine, and fostered, and the defects of its application pointed out and remedied. It is not the successful candidate that alone derives all the benefit of the struggle,—superior merit, where it exists in a happy combination with animal energy, without which genius is trodden to the ground, will always force its way: the higher attainments of knowledge will be acquired by a few for the love of distinction and of science. It is mediocrity that requires to be stimulated; and the true and useful character of the profession will depend upon the skill, not of the few, but of the many.

For these reasons, which might readily be amplified, we are not churlish enough to refuse a few lines of our pages to the names of successful students. But should we find the confidence of young men in the fairness of their examinations abused, there is not an abuse in medicine, at which our indignation has been hurled, which shall have roused us into more bitter hostility than such a depraved dealing with the honesty and generous sentiments of youth. We are glad to see that St. Bartholomew's has imitated King's College and the London University in its resolution to bestow prizes. Private lecturers have been long in the habit of exciting the attention of their pupils in a similar manner.

There is another and no less important view of this subject which has occurred to us. On a former occasion we made some observations on the rules adopted at the College of Surgeons in Dublin for the examinations of candidates. Our readers are aware, that in the latter place the student is regularly examined in a class in each separate branch of his professional knowledge at distinct times,—so that every

year of his course he undergoes an examination in the subjects of the year, and this for the purpose of his degree in surgery. Compare with this the system of attempting to examine a candidate in surgery, throughout his whole course of study, at a single sitting,—when it is left to the caprice of the examiners, who may happen to be present, what corner of the science it may please them to examine concerning:—the worst prepared may slip through, the best prepared may almost fall, and to none is his proper merit given, because the real extent and accuracy of his knowledge is unknown. We think it, therefore, a thing most desirable to engraft upon our system of instruction a system of periodical examination, preliminary to a degree; into which examination every student should enter in his course. These examinations might be also made subservient to the purpose of rewarding the most diligent students. Of course if, as we recommend, they were required of every candidate for a medical degree, they should be under the control and direction of the central medical power. Teachers would cease to be examiners of their own pupils. As to the distribution of rewards, that would depend upon the sources from whence they were derived. If a particular school contributed its own prizes, its own students should alone share them. But, at the same time, we have that confidence in the public spirit of enlightened individuals, that, in the course of a short time, we should expect to see rewards offered to general competition:—and we suggest a small portion of the funds of the College of Surgeons could not be more usefully applied. We know of so many instances of the abuse of College exhibitions, (by which College phrase is understood annual allowances of money for five or seven years generally to the

successful candidates in a certain examination,) that we are no great advocates for that manner of rewarding merit. A sum of money is always an agreeable present;—an annuity too often leads to neglect and idleness. Prizes of this nature are, however, upon a scale of magnificence beyond the measure of ordinary liberality. But as other branches of science, mathematics and so forth, have had their liberal encouragers and benefactors in the Universities, so we fondly hope medicine will not be destitute of liberal patrons, to whom our observations may be applicable.

We have said nothing of the encouragement to be given to those already within the profession, in order to promote and extend the practical knowledge of medicine, and enlarge its boundaries. We may engender very useful habits in the student, we may sow in him the seeds of discovery, we may rouse his inventive genius; but it is to the actual practitioner we must look for the augmentation of a practical science; and, although it may be said, in some measure truly, that the genuine disciple of Hippocrates is pretty sure of that best of patronage, the public support, still we believe more money has been made by the authorship of a popular work with a *very* popular title, whereof our Fellows have published not a few, than by the ablest treatise, purely medical, which is unknown, except to the members of the profession. To such obscurations of talent our profession is peculiarly subject. Of divinity we say nothing. Of law it may be said that, in general, those who enjoy eminent practice give public experience of their fitness; and besides, there is no demand for the power of philosophical deduction in the practice of jurisprudence—it is a system of mere logic. But in medicine, a science of observation never to be exhausted, the judg-

ment of the public, as to the merit of the practitioners, is formed upon the most inaccurate grounds. In law, it matters little to a future race how much talent may have been under a cloud in a preceding age. But in medicine, humanity is interested in calling into action the greatest talents of every age. Prizes, as marks of distinction, may do something towards the due promotion of medicine as a science; and still more may be done by a proper disposal of what may be called medical patronage,—the offices of honour or dignity in the profession, which ought to be in the disposal of responsible authorities.

VALUE OF SCOTCH DEGREES IN ENGLAND.

It is very singular that at this moment a case is pending in the King's Bench, in which a question is for the first time raised, as to the value and effect of a Scotch Degree in this country. The case is Collins against Colnaghi. The plaintiff has, it seems, a St. Andrew's Degree in Physic, and brought an action against the defendant for some slanderous words in reference to his character as a Physician, denying that the plaintiff was a Physician, &c., &c. The point now awaiting the decision of the judges is, whether the circumstance of the plaintiff having a Scotch Degree would enable him to maintain an action for words spoken of him in reference to his character of Physician in this country.

This question is now no more interesting than that a decision upon it should be called for at such a moment.

SIR CHARLES WETHERELL AND THE LONDON UNIVERSITY.

WE opened with some interest the authorised edition of the speech of Sir Charles Wetherell against the London University. We were well aware of the grotesque

humour of this eminent lawyer and statesman. We had often admired the strange melange of sound sense and extravagant incongruous conceits which abound in his speeches; and, upon such a subject, where ardent attachment to his venerable client, the University of Oxford, and as keen contempt of their antagonist and of its public supporters, alike influenced him, we expected no ordinary out-pourings of his peculiar spirit. Although there is enough of Sir Charles's idiosyncrasy in the speech to identify it, we are, on the whole, sadly disappointed in our expectations of a feast of fun for our readers. The best thing in it is the last. Sir Charles thus perorates:—

“My Lords, before I leave this subject, I cannot but remind you of the infinite danger of that principle of liberalism on which this London University is to be founded. It carries with it an absolute contempt of the national church, and what is still more dangerous, a contempt of those feelings of affection and attachment by which the people of this country are bound to it from a sincere belief in the purity of its religion. The King by his charter is to found an *atheistical* institution, which will operate like the liberal proclamation of indulgence which issued from that ill-fated monarch, James II., in conjunction with his coadjutor, Lord Chancellor Jefferies, sometimes the tool of the sovereign, sometimes misled, and sometimes misleading the sovereign, of whose great seal he had the custody. Let any man say whether this is less to injure and insult the established church than was the attempted intrusion of Catholicism by James II.; and not less will the public indignation be excited, and their feelings violated by an attempt to abolish all true religion, and to substitute *perfect infidelity*.”

Should Sir Charles ever think of de-

dicating this work to the University of Oxford, in whose behalf he spoke, we would venture to submit, for a dedication, a form of sound words on a former occasion addressed to that learned body. He may say —“I have brought you some fine biscuits, baked in the oven of charity, carefully conserved for the chickens of the church, the sparrows of the spirit, and the sweet swallows of salvation*.”

ST. BARTHOLOMEW'S HOSPITAL.

ON Wednesday the 14th inst. the annual distribution of prizes was made, in the great hall of this Hospital, to the students of its medical school who had distinguished themselves in the several branches of medical and surgical science.

Sir Henry Hallford, Bart., President of the College of Physicians, who received his early medical education at this Institution, was invited to take the Chair.

The following is the List of the Gentlemen to whom prizes were adjudged:—

MEDICINE.

Charles West, Amersham, Bucks, 1st Prize.

Honorary Certificates were adjudged to H. P. Jones, P. Aldrich, and F. Bell.

CHEMISTRY.

Robert Falkner, Bath, 1st Prize.

Thomas Wilson, Congleton, 2d Prize.

Honorary Certificates.

Wm. Hott, J. E. Henry, J. E. Beveridge, and A. B. Evans.

CLINICAL MEDICINE.

William Baly, Lynn, 1st Prize.

SURGERY.

John Gay, Wellington, Somerset, 1st Prize.

G. W. W. Firth, Norwich, 2nd Prize.

G. W. Bell, Edinburgh, 3rd Prize.

Honorary Certificates.

Percival Leigh and Frederick Bell.

ANATOMY.

William Moore, Plymouth, 1st Prize.

R. H. Meade, Bedford, 2nd Prize.

George W. Bell, Edinburgh, 3rd Prize.

Honorary Certificates.

John Henry Clark, Isaac Guillemard, H. P. Jones, W. J. Square, Thomas Taunton, and Thomas Wilson.

* Scott's Life of Dryden, new edit., p. 6.

CLINICAL SURGERY.

Henry Smith, 1st Prize.

Richard Allen, Leicester, 2nd Prize.

Honorary Certificate.

W. Thackwell, Birmingham.

MIDWIFERY.

Richard B. Ruddock, Stockland, Somerset.

Honorary Certificates.

J. F. Harding, T. Sawyer, J. H. Clarke, T. Wilson, J. S. Birch, D. M'Nicholl, H. P. Jones, T. Holdsworth, J. C. Green, — Millar, — Rogers.

FORENSIC MEDICINE.

Prize—H. P. Jones, Pembroke, S. Wales.

Honorary Certificates.

— Aldrich and S. H. Evans.

BOTANY.

Prize—F. S. Taylor.

Honorary Certificate—Henry Taynton.

FRACTURE OF THE LOWER JAW.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—The following case of fracture of the lower jaw, with the means successfully adopted to obviate the difficulties which presented themselves, will, I trust, prove of sufficient importance for insertion in your valuable pages.

July 21st. J. H——, *ætat.* 9, was thrown from a horse, and received a violent kick on the chin. On examination, I found a perpendicular fracture of the lower jaw on the left side near its angle; on the corresponding portion of the right side was a comminuted perpendicular fracture. Two dentes cuspidati on the right, and the bicuspis on the left side, were knocked out; the front incisors, with their alveolar processes, were broken off and lay under the tongue, forming a horizontal fracture communicating with the perpendicular ones. On the posterior superior angle of the right parietal bone was a lacerated wound of the scalp, produced probably by the fall, and another under the left side of the chin. The intermediate portion of the jaw, drawn down by the action of its muscles, lay loose, and made the mouth appear as wide open as occurs in dislocation, from whence blood, mixed with saliva, was flowing copiously, presenting altogether an appearance most deplorable. I should add, there was considerable hæmorrhage from the right ear.

My much esteemed preceptor, the late Mr. Abernethy, when speaking of fractures of the jaw, used to say, "Well, what is to be done

in such a case?—You must put the bone into its old situation, and then you must keep the jaw still. And for splints, get some thick pasteboard, soak it in water till soft, and shape it to the jaw, and keep it steadily compressed till the pasteboard gets dry." This was the plan first pursued in my case. The wound was dressed with simple cerate, and the bone being put into its "old situation," was secured in a pasteboard splint. The diet to consist of gruel, tea, or toast and water, sucked through a quill.

22nd. Has passed a very restless night. Saliva, mixed with blood, still continues to flow from his mouth. The alveolar processes and teeth have fallen into their former situation; they were again replaced, and the jaw bound up as before. Aperient medicine was given.

23rd. This morning there is considerable fever, with hot dry skin, heaviness, and stupor; the medicine has not acted. Ordered to take a powder of calomel and jalap every hour until stools are produced. The teeth, &c., had again become displaced, though an attempt had been made yesterday to secure them by ligatures of silk to other teeth; they required the same assistance as yesterday, and the intervening portion of bone was more displaced than hertofore.

24th. The bowels have been copiously evacuated, and the unpleasant symptoms of yesterday have disappeared; had some quiet sleep, and is perfectly sensible. A little veal broth was ordered in addition to his diet. The jaw again displaced, and again put into its old situation.

Failing in all my attempts to keep the fractured ends of the bone steadily *in situ*, I took a cast of the boy's jaw in wax, and had a metallic splint, as represented in the drawing, made by Mr. Felton, a very ingenious mechanic in this neighbourhood. In the centre is an upright piece of Britannia metal, which, being flexible, is easily adapted to the form required, and regulated in height by the screw (c).

On the morning of the 28th, the jaw-bone being accurately brought into its old situation, the splint (a a), well padded, was put on, and retained by a broad piece of leather, with two straps on each side, put across the head, and buckled to another piece fastened on the side of the splint at the holes e e. The teeth being also replaced, were confined by the centre

piece. The boy suffered very much from the pain occasioned by resolving the fracture, and pulling the teeth into their proper places; yet in less than half an hour after he was busily engaged sucking the part in his mouth: this had the effect of causing him to retain his saliva, which, up to this time, he had been unable to do. From this period his health continued to be good, and the case went on so favourably, that a cure was effected without leaving any deformity, a circumstance I could not at first have expected.

The apparatus was worn for six weeks, though at the end of five he could bite a hard crust, and masticate his food with as much ease and freedom as before the accident. It was kept on the last week at his own desire, to remove the apprehension which he enter-

tained of the possibility of the fracture giving way when he was eating.

The instrument I consider applicable to all cases of fracture of the lower jaw, the centre piece of course being taken off where its use is not needed; and the great benefit derived from its application in the case related, leads me to hope that, in other hands, it will be found equally serviceable. With this hope, I send the instrument to my respected Demonstrator, Mr. Stanley, of St. Bartholomew's, where cases of this description are of more frequent occurrence than in private country practice.

I am, Gentlemen,
Your obedient servant,
JOHN LEE.

COURT OF KING'S BENCH.

Monday, May 26.

COLLINS v. COLNAGHI.

THIS was an action for slander, tried at the Dorset Assizes, and a verdict found for the plaintiff, with 10*l.* damages.

The plaintiff was a Scotch physician and accoucheur in full practice, and he complained of an injury sustained in his practice by words spoken by the defendant, who was also a physician. The words charged the plaintiff with being an impostor, ignorant of physic, and unfit to practise as a physician.

Sergeant Coleridge moved on a former day for a rule to show cause why the verdict should not set aside and a nonsuit entered, or a new trial had. The application was made on the ground that a Scotch physician was not entitled to practise as a physician in England without the licence of the College of Physicians in London. The jury, he contended, had given damages for an injury sustained by the plaintiff in his practice as a physician, and unless he was legally in the practice of physic, as a qualified M.D., he was not entitled to sustain this action. The prohibition in the universities with respect to degrees in medicine would be nugatory in case the plaintiff having a diploma from a Scotch university could practise in England without a licence. The Acts of Parliament were clearly a bar to such practice, and as the plaintiff had not held the rank of a regular physician he could not support the action.

Mr. Barstow showed cause against the rule, and submitted that the plaintiff, having produced proper evidence of his qualification, namely, a diploma from the University of St. Andrew's, was to be considered a physician, and consequently could maintain the action. The learned Counsel submitted that the evidence proving the plaintiff had obtained his diploma as a physician ought to be received and considered conclusive, unless proof could be shown to the contrary. A person sent to St. Andrew's had proved that he went to that University, where he saw the officer who held the seal of the University, which was the same as that affixed to the plaintiff's diploma. This was sufficient evidence that Dr. Collins was a physician from the College of St. Andrew, and

that he was practising under that qualification when the slander was uttered.

Lord Denman.—You say it was *prima facie* evidence of his practising as a physician.

Mr. Barstow.—I contend that it was sufficient to prove he acted as a physician.

Lord Denman said if a person brought an action for slander injurious to him as an attorney, he was bound to prove he was on the rolls of the Court.

Mr. Barstow cited the cases of *Clark v. Davis*, *Moises v. Thornton*, 8 Term Reports, and another case, to prove that evidence of a Scotch diploma would sustain the qualification of a physician, and therefore it was sufficient to enable the plaintiff to support this action.

Mr. Serg. Coleridge, in reply, contended that a person who complained of slander injurious to the exercise of his profession, was bound, by the practice of the Courts, to prove his qualification. The 3rd Hen. VIII., cap. 2, enacted "That no person within seven miles of the city of London should practise physic without examination before the bishop of the diocese." Subsequent statutes provided that none but graduates of Oxford and Cambridge should practise as physicians without the license of the College of Physicians. The Act of the 5th Anne, for securing the Protestant religion and Presbyterian government in Scotland, provided that the Scotch Universities should continue for the protection of the Church, but there was no provision to make Scotch diplomas legal qualifications to practise physic in England. Upon a general view of all the facts in this case, it seemed that the plaintiff was not in a condition to support the action.

Lord Denman said it was clear, when a person complained of slander injurious to him in the business he was carrying on, that he must prove he was carrying it on legally. The Court thought the learned judge who tried the cause was right in the admission of evidence of the diploma. Unless that evidence had been received great inconvenience would have arisen in a variety of cases. Whether the diploma without a license did not entitle the parties to act as physicians was a question of too much importance to be decided without further consideration.—Judgment postponed.

A similar action was lately commenced in the Common Pleas — *Haycraft v. Benwell*—

and was discontinued on the same grounds as the above; so that it is a question whether a Scotch graduate in physic who practises in England, not being licensed by the Royal College of Physicians of London, is legally entitled to professional reputation. Such a monstrous and unjust state of the laws should no longer continue; and we beg to direct Mr. Warburton's attention to the subject. A physician's reputation may be ruined by slander; it may be reported that he killed his patient; he brings an action for defamation, but the defendant pleads that he is not legally entitled to practise, and to bring an action he must have a legal right; to decide which, the judges must take time to consider, and his prospects may be blasted.

ECLAMPSIA OF YOUNG INFANTS.

M. DUGES explained that this convulsive disease of infancy always depends upon some irritation of the encephalon; that it sometimes is followed by an apoplectic or asphyctic state, and at other times is consecutive to it *. Often while one side of the body is convulsed the other side is paralysed. There is also a strong analogy, if not an absolute identity between infantile eclampsia and the tetanus,

* It not unfrequently happens that the symptoms of eclampsia, of apoplexy, and of asphyxia, are so blended and confused together in new-born children, that it is extremely difficult to distinguish the exciting from the excited disease, or to decide whether they are all of simultaneous occurrence. Very soon after birth, probably the apoplexy generally precedes the eclampsia; and in children more advanced, the latter seems to induce the former.

which has been improperly constituted a peculiar disease, and said to be exclusively belonging to the West Indies. M. Duges has repeatedly witnessed cases of genuine general as well as partial tetanus in infants at home. There are, therefore, according to him, three species of eclampsia, viz. the epileptic, the apoplectic, and the tetanic.

APOTHECARIES' HALL.

NAMES of gentlemen to each of whom the Court of Examiners granted Certificates of Qualification on Thursday, May 22nd:

- Charles Ilderton Croft . . . London.
- Christopher Browing Emmett Hounslow.
- Frederick Foaker . . . Great Baddow.
- Alfred Foote
- Thomas Hayes Jackson . . . East Cowton.
- William Thomas Richardson . London.
- James Wilkes Birmingham.

BOOKS.

An Introductory Lecture on Diseases of the Eye, delivered at the Birmingham Eye Infirmary. By RICHARD MIDDLEMORE, M.R.C.S. 8vo. pp. 36. 1834. J. C. Barlow.

An excellent lecture, evincing great experience on the author's part with diseases of the eye.

CORRESPONDENTS.

The illness of the gentleman who reports Dr. Stokes's Lectures prevents us from giving one this week. We expect to resume them in our next.

VOL. V.

LECTURES ON THE PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY, BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE XCII., DELIVERED APRIL 22, 1833.

GENTLEMEN,—*Cancer of the tongue* commonly begins as an irregular, rugged, unyielding knob, generally situated in the anterior third of this organ, midway between its raphe and its edge, the mucous surface being puckered and rigid, and the patient experiencing severe pains in the part, which shoot towards the ear. Sometimes the knob acquires considerable size before ulceration commences. It is alleged, that persons, about the age of forty, are most subject to cancerous disease of the tongue. The glands of the neck after a time become swollen and indurated, and profuse bleedings are disposed to take place from time to time, whereby the patient becomes extremely weakened and reduced.

There are two methods of extirpating cancerous portions of the tongue; one by the knife; the other by a double ligature passed through the centre of the part by means of a sharp pointed curved needle fixed in a handle, one portion of the ligature being firmly tied over one side of the organ; and the other portion over the other side. In doing this operation, some surgeons first take hold of the tongue with a pair of hook forceps, so as to fix it. The objection to the knife is the hæmorrhage, which, if profuse, would require some extraordinary means for its suppression, such as the application of the actual cautery, or even securing the lingual artery as it passes over the cornu of the os hyoides. When the extirpation of a cancerous induration can be accomplished by removing a piece of this organ in the shape of the letter V; the best mode of stopping the bleeding is to bring the sides of the wound closely together with a suture.

VOL. V.

Gentlemen, you should be aware that relapses are frequent after operations on cancerous tongues; a fact that will make you cautious in the judgment you give respecting the chances of a cure. Be sure not to promise too much.

Let me next speak of *dividing the frænum of the tongue*. I may at once tell you, gentlemen, that children are not so frequently tongue-tied as nurses and mothers imagine; and you may be sure, that when once an infant has been able to suck properly, whatever may be its present inability to do so, it does not proceed from the confinement of the tongue by the frænum, but probably from the large size of the nipple, excoriation of the lips, or other causes, which should be investigated.

When the frænum really ties the tongue too closely to the bottom of the mouth, the surgeon will find that he cannot raise the tongue to the palate with his fingers. Sometimes, however, the frænum is really so short that it interferes with the requisite movements of that organ in sucking, deglutition, and the articulation of words. The surgeon is then called upon to divide it, which may be done with a pair of sharp scissors, care being taken to direct the incision downwards, so as not to injure the raninal vessels.

An immoderate cut gives rise to two dangers; one is, that of hæmorrhage; the other, is that of the tongue being left so unfixed, that it may be thrown back into the pharynx in the act of deglutition, so as to cause suffocation. A similar danger has been exemplified after the operation of removing the lower jaw.

With respect to hæmorrhage, children are constantly disposed to suck and swallow whatever comes into their mouths, and hence they sometimes die with their stomachs full of blood, even when only the branches of the raninal artery are wounded, and not the trunk itself. Nay, it is alleged that the veins have sometimes yielded a dangerous quantity of blood, that has been swallowed in this manner.

Ranula is a tumour situated under the tongue, and commonly believed to arise from

P P

a dilatation of the duct of the sub-maxillary salivary gland. The swelling is usually situated on one side of the frænum, and, when large, extends forwards under the apex of the tongue. Its contents are generally a glairy fluid, resembling white of egg; but if the tumour has been of long standing, their consistence may be much thicker, and even blended with calcareous matter. Neglected *ranulae* may attain a considerable size, and not only obstruct the movement of the tongue, but even produce serious annoyance and mischief to the teeth and lower jaw-bone by their pressure. In general, however, when they have become as large as a walnut, they burst; the opening heals up, and then they fill and burst again.

No doubt some *ranulae* do arise from obstruction of the duct, the orifice of which, therefore, should be examined; and if a piece of calculus can be felt with a probe, it should be removed; this alone would lead to a cure. In ordinary cases, you may cure the disease by opening the swelling and snipping off a portion of the sac, so as to prevent the part from closing again. Merely opening the cyst, without the excision of a portion of it, will not suffice. It is also a good plan to apply a bit of lint, dipped in a strong solution of lunar caustic, to its inner surface. I have lately been attending a young lady for a *ranula*, that would not yield to any ordinary modes of treatment. I opened it, and removed a considerable piece of cyst, filling the cavity with lint, but this plan failed. I then cut away a second piece of the cyst, and dressed the cavity with lint dipped in a solution of nitrate of silver: this also was followed by a relapse. I then passed a seton through the *ranula*, and kept it applied for two or three weeks in vain. Lastly, I made a small opening, and put into it a little silver tube, which was worn about five or six weeks, and the disease never returned. The latter treatment of *ranula* by puncturing it, and placing in the opening a small tube not quite half an inch long, and made with a rim, by which it is retained in the part, is frequently adopted by Dupuytren.

Tonsils.—When the tonsils are so considerably swollen, from an attack of acute inflammation, as seriously to obstruct deglutition and respiration, they should be freely scarified, after which, the bleeding from them, assisted by venesection, leeches, and other antiphlogistic means, will in general quickly bring down the enlargement.

If the same inconvenience should arise from the formation of matter, the abscess should be opened with a double-edged bistoury, the blade of which may be partly covered with lint to keep the edges from wounding the tongue.

Gentlemen, the tonsils are also liable to a chronic enlargement, more especially in scrofulous subjects. They may, indeed, swell to

such a magnitude as to close the aperture between the mouth and pharynx, and create a total impediment to swallowing, and much difficulty of breathing.

If these enlargements resist the internal use of iodine, or small doses of sublimate with tinct. rhei et cinchon., and the application of lunar caustic, or nitric acid, the tonsils, or rather the redundant portion of them, should be extirpated by means of a ligature or cutting instrument. Chelseden's plan of passing a ligature through a diseased tonsil, by means of a crooked needle fixed in a handle, and with an eye near its point, is not a bad method; but the removal may be safely performed with a hook and large scalpel, for the hæmorrhage is never serious.

Elongation of the Uvula.—The uvula is sometimes thickened and considerably elongated, producing great uneasiness about the throat, and irritation of the epiglottis. If the disease cannot be remedied by astringent gargles, the best plan is to snip off the superfluous length of the part with a pair of scissors.

Diseases of the Gums.—The gums in the natural and healthy state are not very sensible: they may be divided with a lancet without much pain; and the pressure of hard substances against them in mastication is not productive of any injury. When, however, they become inflamed, in consequence of decayed teeth, a cold, or any other cause, they cannot be touched, or pressed upon, in the slightest degree, without the patient being put to a great deal of suffering.

Some of the diseases of the gums originate from those of the teeth, while others have no connexion with this cause.

The *Gum-Boil*, or *Parulis*, is merely an abscess of the gums, generally arising from the irritation of a diseased tooth, though sometimes from disease of the alveolar process, or from splinters of this part left after the extraction of a decayed tooth. These abscesses are to be treated on common principles, and opened with a lancet as soon as matter is formed; afterwards, when the part has become quiet, the decayed tooth, if there be one, should be taken out.

If the gum-boil becomes fistulous, it must be freely laid open, and a solution of lunar caustic applied.

Epulis; or, Excrescence from the Gums.—The fibro-vascular texture of the gums is much disposed to produce fungous and other excrescences. Any kind of irritation, as that of bad teeth, or a severe blow, will sometimes lead to the growth of considerable tumours from the gums; and occasionally they arise without any manifest exciting cause.

The texture of an epulis is generally soft, spongy, and vascular, but sometimes hard, fibrous, incompressible, and not endued with much vascularity.

A soft vascular epulis mostly originates from the gum itself; while that which has a

fibrous or fibro-cartilaginous structure frequently grows from the alveolar process. When the excrescence first makes its appearance between sound teeth, which it afterwards loosens and forces out, you may conclude, that the disease originates from the periosteum and interior of the socket.

As tumours of the epulis kind have no disposition to recede, and, when they originate from the periosteum or bone, are disposed to assume a malignant character, I cannot too strongly insist upon the necessity of an early operation for their complete removal. The knife is the best means for the purpose. Any teeth in the way should be first extracted; the whole substance of the swelling removed; the bone and periosteum scraped; and even a portion of the jaw removed with Hey's saws, or Liston's cutting forceps, if found to be diseased. In France, the cautery is usually applied after the removal of a cancerous epulis.

The manner of removing the diseased portion of alveolar process is, to make a perpendicular cut through the bone on each side of the tumour with a fine saw, when its separation may be completed with a strong pair of forceps. The bleeding is profuse, but may be stopped by pressing on the wound a dossil of lint dipped in the tincture of muriated iron, the application of which, or of a solution of lunar caustic, may be repeated, if necessary, at each succeeding dressing.

Polypi of the Nose.—They are swellings arising from the mucous membrane of the nose, and generally consisting of a soft substance easily torn, streaked with a few vessels, and of a light yellowish or grey colour, and not endued with much sensibility. The disease is most common in persons between forty and fifty, though occasionally met with in younger subjects. The mucous membrane of the nose is particularly often the seat of them. The polypi, which have the character now enumerated, are not of a malignant nature, and whatever inconvenience may be produced by them is caused by their obstructing the nostril, and by their pressure on the adjacent parts. They are commonly of a pyriform shape, though, if they are large, their figure is in a great measure determined by that of the cavity in which they grow; but whatever may be their shape, they are invariably connected to the mucous membrane by a narrow stalk or pedicle, sometimes termed their *root*. They rarely or never grow from the septum nasi, but usually from a point at or near the upper os spongiosum.

The polypi, whose texture corresponds to what I have mentioned, are those mostly met with, and often named *soft* or *gelatinous polypi*; or occasionally *mucous polypi*, from their structure bearing a considerable resemblance to the mucous membrane from which they originate; or *benign polypi*, in consequence of their having no disposition to assume a dangerous morbid action. Sometimes they are of a firmer consistence and fibrous texture,

when they are termed *fleshy polypi*; but these are more frequently noticed in the uterus than in the cavity of the nose. Another kind of disease, gentlemen, is improperly called the *malignant polypus*, because it is not truly a polypous excrescence at all, but a tumour, partaking in every respect of the nature of fungus hæmatodes, or medullary sarcoma.

In many cases, several polypi of different sizes occur in one or both nostrils. Sometimes you meet with only one; and, in particular examples, the nostrils are filled with a peculiar kind of polypi, consisting of cysts or vesicles, filled with a colourless fluid: these are *vesicular* or *hydatid polypi*, as they are termed, and are not uncommon in children, and very young persons.

Truly cancerous polypi are said, occasionally, to take place in elderly persons. I believe they are very uncommon: the malignant polypi, which I have seen, were evidently specimens of medullary sarcoma.

The common pendulous soft benign kind of polypus, as I have already informed you, generally grows from the external side of the cavity of the nose, and, in many examples, from the mucous membrane covering the ossa spongiosa. The growth of a polypus from the septum narium, if it ever occur at all, is so uncommon, that some surgeons of the most extensive practice have never seen an instance of it. The commencement of the disease is attended with a feeling of obstruction in the nose, like what is usually felt in an ordinary catarrh, the obstruction being more considerable in wet than in dry weather. These polypi, when under a certain size, may be made to advance or recede by the force of the breath in inspiration and expiration. The sound of the voice is nasal, and there is generally some uneasiness felt about the frontal sinuses.

Sometimes, when a polypus becomes large, it passes towards the velum pendulum palati, over which a part of it hangs towards the pharynx; or if it originate towards the back of the nares, it may take the same direction, instead of towards the nostril. In certain examples, you will see polypi projecting in both directions.

Common polypi cannot be cured by local applications; caustic only acts upon their surface, and cannot get to their root. They grow indeed faster than any caustic can destroy the superficial parts of them.

Extraction, excision, and the ligature are the three means of curing nasal polypi. Extraction is the method usually preferred, and is accomplished with forceps made for the purpose, and of different shapes and sizes. Some are slightly curved, and formed with oval excavations on the inside of the ends of the blades, and also with an aperture in each of them. Others are straight, and the inner surfaces of the blades furnished with projections, or teeth. Occasionally polypus forceps are made with serrated blades, which, when

shut, meet in the manner of a suture of the cranium.

The patient being seated opposite a strong light, the surgeon first examines the extent and situation of the polypus with a probe, endeavouring in particular to make out the point of its attachment and the place of the pedicle. This cannot always be done, but you know that the os spongiosum superius, and the outer and upper side of the nostril, are the common situations for the attachment of the polypus. You, therefore, convey the forceps in that direction, and endeavour to seize the pedicle. If you succeed thus far, the best plan is not to pull it directly outwards by a jerk, but to twist the tumour from its connexion.

The hæmorrhage from soft benign polypi is never dangerous, though sometimes copious.

As this is a disease very likely to return, and, unless a layer of bone come away, we are never certain that a portion of the root may not be left behind, it is prudent, after the operation, to direct the patient to inject two or three times a-day up the nostril a strong astringent lotion, containing alum, or the muriate of ammonia.

When a polypus projects backward, towards the throat, it is sometimes taken hold of with a pair of curved forceps, introduced from the mouth, and extracted. But you will frequently find another part extending forwards, which you may first begin with. In this manner you may perhaps succeed in breaking the pedicle, and both portions may then be readily extracted. Much of the operation is necessarily performed, as it were, in the dark; for, after the bleeding begins, nothing can be seen.

Supposing you get out only a fragment of the polypus at first, you should not stop, but try to extract the rest, either piecemeal or in one mass, just as you find practicable.

Excision is a plan occasionally applied to large polypi extending back towards the throat, and having a pedicle, the situation of which can be felt and reached with a pair of long probe-pointed scissors. The bleeding need not be feared; but, as far as my experience goes, you seldom know the precise situation of the pedicle, or can reach it sufficiently well with scissors, to make this method very advisable.

The *ligature* has also been applied to similar polypi extending towards the throat. The noose of a ligature, or piece of wire, is introduced through the nostril to the back of the throat, where it is put over the tumour with the aid of a pair of forceps. The ends of the ligature, or wire, hanging out of the nostril, are then passed through a double canula and twisted. It is a practice rarely adopted in this country. The best instruments for this operation are those of Græfe.

Vesicular or *hydatid* polypi generally grow again. You may clear the nostril from them but they return. One plan, to which they

will sometimes yield, is that of applying strong astringent lotions to them. They should first be removed, and the lotion then applied by means of lint.

With respect to the malignant kinds of polypi, they are out of the power of surgery; all that can be done is to lessen the patient's sufferings by narcotic medicines, opium, hyoscyamus, and hemlock.

Wounds of the Throat are cases of frequent occurrence in persons who attempt to commit suicide. Some merely penetrate the integuments, and are not of any particular importance. Others extend more deeply, and divide some of the primary branches of the external carotid, especially the lingual and the superior thyroid arteries. Others make an opening into the mouth by separating the os hyoides, tongue, and epiglottis, from the thyroid cartilage; while others are situated lower down, so as to penetrate the thyroid cartilage, or betwixt that cartilage and the cricoid, and sometimes through these into the œsophagus. You will meet with more wounds of these parts, than of the trachea itself; for persons who aim at suicide generally make the wound high up in the neck, and, unless they cut with great determination and violence, they do not reach the carotid, or internal jugular vein. Some individuals, however, in a desperate state, reach these vessels, even high up in the neck, dividing nearly every thing down to the vertebræ. Under these circumstances, they are, of course, immediately destroyed by hæmorrhage.

In ordinary cases, when there is much bleeding, it is from the lingual, or superior thyroid artery. Then also the patient, if not promptly assisted, may die from loss of blood, but more frequently he faints, and this is followed by a temporary stoppage of the hæmorrhage; and time is thus afforded for a surgeon to be sent for.

I have known a patient die in about twenty minutes after cutting his throat, though no artery of any size was wounded, and the hæmorrhage on the whole was very trifling. Thus one of my patients in the King's Bench cut his throat last autumn, dividing the trachea, and the external jugular vein. As he did this when he was alone in his room, the occurrence was not known to any other person for nearly twenty minutes after it had taken place, and when the gentleman who assists me in the duty arrived, the patient was at his last gasp. On examination after death it was found, that no large artery was cut, but the stream of blood from the external jugular vein had passed into the trachea, and caused suffocation.

I have also lately had another patient in the same place, who, after the nurse had retired to rest, took out his razor and cut his throat. A girl accidentally entered the infirmary directly afterwards, and seeing the stream of blood which went as far as the middle of the room, she gave the alarm, and a surgeon in the prison immediately secured the superior thyroid

artery that had been divided. In all cases of this kind the bleeding vessels are to be secured by ligature. The edges of the wound are then to be brought together by position. For this purpose the patient is to be put in bed with his head and shoulders raised, and the chin inclined towards the sternum. This posture is to be maintained by a bandage passed round the night-cap, to which it must be fastened, while its ends are to be sewed to a band round the chest. Gentlemen, I scarcely need say that the patient requires to be continually watched in order to prevent him from doing further violence to himself.

Sutures for keeping the edges of a wound in the trachea together on account of the irritation which they cause, and the impossibility of uniting wounds of that tube by the first intention, I think, are not so often employed by modern surgeons, as by their predecessors. When the division of the trachea is extensive, one or two stitches may, however, be passed, without transfixing the mucous membrane; but, generally speaking, position is the great means of keeping the parts together.

When the wound is a severe one, or when it penetrates the mouth, or œsophagus, an elastic gum catheter should be passed down the latter canal, and all food and medicines introduced into the stomach by means of a syringe. You will thus prevent the disturbance of the wound that would otherwise be produced by the action of deglutition. Bleeding and other antiphlogistic means are frequently necessary.

During my service in the army, I had opportunities of seeing many extraordinary wounds of the throat and neck. Thus, after the battle of Waterloo, one man was brought into my hospital, who had received the thrust of a lance in the throat, by which the mouth was laid open, the tongue dreadfully lacerated, and all the primary branches of the external carotid were wounded, and consequently it became necessary to tie the common carotid artery. This operation, performed by Mr. Collier, succeeded in suppressing the bleeding, and the patient recovered. At the attack on Bergen-op-Zoom, I saw a soldier the whole of whose lower jaw, with the soft parts attached to it, had been carried away by a grape-shot. This poor fellow recovered, and was much indebted for this favourable result to the aid derived from elastic gum catheters. In another example, a musket-ball had injured the carotid, in the lower part of the neck, which gave way about ten minutes after the soldier had been placed in the hospital, and he died of the pressure of the effused blood on the trachea, so suddenly, that there was no time to make any attempt to save him.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS AND CHILDREN,

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE XIX.

Influence of Morals, Seasons, and Climates on Infantile Mortality—its State at Different Periods—Causes of its Diminution—Decrease of Small-pox—Proportional Mortality of the Sexes—and of Infants and Adults—Infantile Therapeutics—Difficulties of determining the proper Doses of Medicines—Medical Posology—Ancient and Modern Doses—Rules for Prescribing Medicines.

GENTLEMEN,—The most fertile source of infantile mortality is illegitimate unions. In such cases proper parental care is scarcely ever afforded to infants, and debility, disease, and death, are the usual consequences. It is difficult to ascertain the proportion of illegitimate to legitimate births in this country, but it must be very considerable. According to Mr. Robertson, it is 1 in 12 in Manchester, 1 in 20 in Sweden and Finland, 1 in 3 at Stockholm, 1 in 11 after the revolution in France, and since that period, above 1 in 3 in Paris, or 36 per cent.

The mortality of illegitimate infants is immense. According to Dr. Caspar, it was 15 per cent. at Gottingen, 1 in 12 in Berlin, from 1819 to 1822. "For 10 legitimate infants who die in the first month, there are lost 24 natural children. In the second and third months the proportion is 2 to 1. In the second quarter it is $1\frac{1}{2}$ to 1. In the two remaining quarters of the first year, it is $\frac{1}{2}$ to 1. In the second year $1\frac{1}{2}$; in the third and fourth $1\frac{1}{2}$; in the fifth, sixth, and seventh, $1\frac{1}{4}$; and of the total number of natural children, only one-tenth or one-ninth pass the age of puberty."

The comparative mortality of the sexes after birth may be estimated from the following statements. Of 20,117 births in the Dublin Lying-in Hospital, 10,647 were boys, and 9,470 girls. The deaths of the males exceeded that of the females by 694.

Infantile mortality is influenced by sea so and though accurate returns have not been obtained, it appears by tables kept in London, at Glasgow, and Liverpool, that the greatest number of deaths occurred in the following order of the seasons:—in London, autumn, spring, winter, summer; at Glasgow, winter, autumn, summer, and spring; at Liverpool, autumn, summer, winter, and spring. The largest mortality of autumn may perhaps be attributed to the great prevalence of bowel complaints at that season, to which children are so very liable.

The seasons have much influence upon

fecundity, and an immense number of facts have proved that there is the widest difference between the seasons of the greatest fecundity in different climates. It is generally considered, however, that autumn is the least favourable period of the year to the reproduction of the species. The end of winter and beginning of spring are the most favourable periods of the year to conception. The mortality of infants in savage countries is, of course, much greater than in civilised nations, and it is also larger among dry-nursed or hand-fed children, and those of hired wet-nursed, than among those who are suckled. In proof of this statement, the deaths have wonderfully diminished in foundling hospitals since lactation is afforded.

If we contrast the comparative mortality of children before and since the commencement of the present century, we shall find the actual deaths, under the age of ten years, universally less than they were in the former period. On the average of the six years preceding 1803, 1 out of 43,666 died annually in this country; but on the average of the ten years preceding 1811, the mortality had fallen to 1 out of 47,697. Mr. Milne ascribes the improvement to vaccination. In 1821 the annual mortality was 1 of 52.7.

"So great an increase of infantile life," says Mr. Robertson, "does not depend alone on vaccination, but upon many causes, of which, nevertheless, vaccination is the most prominent; of other causes, improved habits of living, and cleanliness among the lower orders, the more enlightened domestic management of the sick, particularly in febrile cases, and better medical treatment, are the most remarkable."

The decrease of mortality under the age of ten, is equally remarkable in France. In 1780 half the children died within the first two years. In 1825 the proportion was 38.3. In the former period 55.5 died under the age of 10; in the latter 47.7 only. Of 100 births 21.5 attained the age of 50 in the first period, and, in 1826, 32.5. (*Arch. Gen. de Med.* 1826.)

Since the introduction of vaccination, the mortality in the registers has diminished under the age of two years; and increased between 2 and 10. This is accounted for by the fact, that, as small-pox generally committed its ravages under two years of age, a greater number of children now survive to the age of four or five, and the number of this age being greater than before, measles, scarlatina, hooping-cough, and croup, which always occurred later than small-pox, find proportionally more victims. Dr. Watt, of Glasgow, considered that, as small-pox was now nearly extinct, measles had become more dangerous. He supposed that small-pox improved the constitution, and eradicated deviations from health, and secured the system from other diseases. It is surprising to observe that Sir Gilbert Blane, Mr. Milne, and the late Dr. Duncan inclined to

this opinion, though every one's experience and observation must have proved it erroneous. Most medical practitioners, I imagine, must have observed the evils resulting from small-pox, the evolution of scrofula, the formation of abscesses in different parts, the excitation of tubercles in the lungs, the suppuration of the joints, the loss of vision, &c., consequent to that horrible disease. Besides, the fatality of small-pox was often as great as that of plague; and the profession in all countries have hailed the Jennerian discovery as one of the greatest ever made. Those, who have written on small-pox, adduce the amplest proofs of its fatality, and of its evil consequences or sequelæ. I might cite many writers, but I shall content myself with one of the most eminent, whom I am proud to call my friend. Dr. Sanders, of Edinburgh, in his account of a variolous epidemic, observes, "great numbers, whom the disease did not deprive of life, were much disfigured, and rendered irrecoverable invalids. In some were hideous scars; in others the eyes, ears, and mouth were destroyed; some were lame from inveterate ulcers; others laboured under pernicious internal disorders; and it is certain that water in the head has suddenly destroyed many who seemed to be recovering from the most benign small-pox." If this be true, and no practitioner of experience will, I believe, deny it, we cannot admit the opinion, that "small-pox, when in full force, improved the constitution." For myself I am astonished that any eminent member of the profession could maintain such a doctrine, neither can I assent to the opinion of the above authorities, that the increased mortality of measles is the effect of vaccination.

I feel convinced that vaccination produces no permanently morbid effects upon the constitution; and the concurrent testimony of the Vaccine Boards has long since established the validity of this position. Those who entertain the opposite opinion should have shown (and they have not as yet done so), that a greater number die of measles now than before the discovery of vaccination.

M. Robertson well observes, that small-pox cut off all the delicate children and left the strong and vigorous only to encounter other diseases. But now vaccination preserves all children, and leaves the delicate to survive, consequently these will suffer most from infantile diseases, whether measles, scarlatina, croup, hydrocephalus, &c. There cannot be a doubt, I imagine, but many infirm children are now attacked by measles, &c., who formerly would have been destroyed by small-pox. Moreover, the measles does not now destroy nine-tenths of the children attacked, as was the case with epidemic small-pox; it therefore is not such a formidable disease.

It is lamentable to know that there are persons who diffuse the poison of small-pox, and that medical men are found to participate in this outrage on society. This is an indictable offence, but prosecutions are so seldom

instituted, that the law is scarcely enforced. Some assert, that the legislature could not think of interfering with the liberty of the subject, by enacting a law for the diffusion of vaccination and the extinction of small-pox; but I feel convinced such a law would be most beneficial to society; and there are several precedents in favour of it, which, in many civil and criminal cases, are much more outrageous to the liberty of the subject. I need scarcely observe, that there was no hesitation in passing a law for the prevention of cholera in 1832, founded on the erroneous notion of the contagiousness of that disease, and which outraged the best feelings of humanity. But owing to the supineness of our corporations, the state of medical police is the most imperfect in Europe; and we therefore cannot be surprised at the numerous abuses which are allowed to exist, to the great injury of the public.

It is true, that the heads of the profession have patronised vaccination; and it is the bounden duty of every practitioner to encourage it,—to point out the evil consequences of small-pox,—which cannot fail to convince parents of the danger of that disease, and to impress upon their minds the mildness and anti-variola property of vaccination.

It must be admitted, that a modified kind of small-pox may occur after vaccination; but it is a mild disease, does not deform the countenance, or destroy the eyesight, or induce the long catalogue of distressing and dangerous complaints already detailed.

There is another interesting topic connected with the comparative mortality of infants, which deserves to be noticed.

It appears, by the registries of births in most countries, that more males are born than females; and also, that more of the former die under the age of ten years than of the latter. In England and Wales, for a period of twenty-nine years, for every 10,426 males there were 10,000 females born; in France, 1000 to 938; in the Low Countries, 1000 to 947; in Naples, 1000 to 956. The greater proportion of males was observed wherever the subject has been investigated. It is to be remembered, that more males than females are still-born, and therefore the mortality is greater than the above.

It is generally admitted that polygamy perpetuates a superabundance of the female sex, and this was urged as a reason for the sanction of a plurality of wives. It is also determined that polygamous animals produce more of the female sex—ewes, she-goats, heifers, than rams, he-goats, or bulls. The same result is observed among birds. (Harvey, *de Generatione*; Willoughby, *Ornithol.*) “A man,” says M. Virey, “who cohabits with several women is enfeebled by multiplied enjoyments, whilst his spouse, who, if I may use the expression, does not possess more than the fourth or third of a man, ought to predominate in the act of generation. It therefore results, that she sur-

nishes the advantage of her sex in propagation, and produces more females than males. This is the effect which generally follows in those unions in which the husband is relatively the most feeble.” (Dict. des Sciences Med., Art. FECONDATION.) Hippocrates was of this opinion. (De Genitura.) Forster gives many examples of this fact among the different polygamous nations which he visited. (Obs. on the Human Species, in the Second Voyage of Capt. Cooke.)

In those countries, on the contrary, where the people live without wars, emigration, or excessively laborious employments, and enjoy naval and other commerce, there is a superabundance of males among the monogamous, more especially in cold climates. This predominance is observed in all northern nations; and wherever Europeans pass into other countries.

It is held by some, that the sex of the most vigorous parent is transmitted to the foetus (Virey, Marc, Velpeau, Duges, Girou); and that males are procreated by vigorous and well-nourished parents, and females by those who are feeble and delicate. (Leroy, Bailly, Velpeau, &c.) This may be true as a general rule, but it is liable to many exceptions. I have enquired about the comparative number of male and female children in different families, and have frequently been informed that, though the ladies appeared more delicate than their husbands, females predominated.

Mr. Milne is of opinion, that females are more numerous when the parents are young, and when the offspring is illegitimate; and he instances Wales, where marriages are contracted late in life, compared to England, and the proportion of male births to female is greater in the latter than in the former.

The number of births for twenty-seven years in the Dublin Lying-in Hospital was 20,117, of which 10,647 were males and 9470 females,—a proportion about 9 to 8.

From the preceding statements, it appears that the average mortality of children is in the proportion of 1 in 4 or 5, while, according to a late writer on medical statistics, that of adults is the following:—

“The annual deaths, on an average, throughout the whole of England and Wales, are nearly one for every sixty inhabitants. In the Pays de Vaud the average mortality is 1 in 49. Sweden and Holland present the same standard, or nearly 1 in 48. Next on the list is Russia, where the mortality is 1 in 41. In France 1 dies annually out of every 40—a proportion similar to that of London. It is calculated, that in France about one half of those born live to 20 years, while a third live to 45 years. The lowest annual mortality is at the age of 10, when it is only 1 in 130. At the age of 40 it is 1 in 53. The probable duration of life in France, at the age of 50, is 23 years. The mortality increases among the poor, and diminishes among the

affluent. In the wealthy departments of France, life is protracted 12 years beyond its course in those who are poor. According to Dr. Hawkins, a recent writer on medical statistics, the conservative tendency of easy circumstances is strongly evinced in England. In proof of the same, is the very inferior degree of mortality and disease which occurs among persons insured at the various life-offices. It was found in 1810, that the deaths, which had occurred among 63,000 persons, insured during 30 years, were only 1 in every 81, 12 being in the proportion of only 2 to 3 of what had been anticipated from the ordinary tables of the probabilities of life. Among these *selected* lives, the mortality of the women was still less than that of the men; females in the middle classes enjoying a remarkable exemption from fatigue and harrass. Of 1000 members of the University Club, only 35 died in three years, or about 1 in 90 annually. It is stated, that of 10,000 pupils, who passed in different years through Pestalozzi's institution, in Switzerland, not one died during his residence there. They were chiefly youths, but of all countries, constitutions, and ages; generally, it is to be observed, in easy circumstances. Pestalozzi, also, paid particular attention to their bodily exercises. On the scale of comparative mortality, Austria follows France; the annual mortality being in the proportion of 1 in 38. In Prussia and Naples it ranges from 1 in 33 to 35. The average mortality of the principal cities of the south of Europe is as follows:—Leghorn, 1 in 35; Madrid, 1 in 29; Rome, 1 in 25; Palermo, 1 in 31.

“At Geneva, in Switzerland, correct tables of deaths have been preserved since 1560, and the results are in the highest degree curious and satisfactory. It appears that, at the time of the reformation, half the children born did not reach 4 years of age: in the 18th century it increased to above 27 years. We arrive hence at the remarkable conclusion, that, in the space of about three hundred years, the probability of prolonged life to a citizen of Geneva at his birth, has become five time greater. The *mean life* was thus: in one century, eighteen years; in the next, it grew to twenty three; in the middle of the next, it rose to thirty-two; and, finally, during the present century, from 1815 to 1826, it amounts to thirty-six years.”—*Journal of Health*, No. 7, 1830.

The following account was presented to the Academy of Sciences in Paris, in September, 1833.

“M. Moreau de Jonnes stated some interesting results of his inquiries. It appears that the difference in the mortality of different countries is much greater, than the difference in the number of births—the maximum of the former exceeding the minimum nearly three-fold [22, 59], whereas the maximum of reproduction is not higher than double the minimum. The mortality in the Roman

states, in the old Venetian territories, in Greece and Turkey amounts to 1 in 30,—in the Low Countries, in France and in Prussia, 1 in 39—in Switzerland, Austria, Spain and Portugal, 1 in 40—in Russia and Poland, 1 in 44—in Germany, Denmark, and Sweden, 1 in 45—in Norway, 1 in 48—in Ireland, 1 in 53—in England, 1 in 58—and in Scotland, 1 in 59. The two leading causes which influence the population of a country, are its climate, and the degree of its civilisation. A cold climate is certainly more favourable to life than a warm one; and if we examine the rate of mortality in countries within the torrid zone, it is much higher than in one of more temperature; thus in Batavia, it amounts to 1 in 26—in Trinidad, 1 in 27—in Martinique, 1 in 28—at Bombay, 1 in 20—at Havannah, 1 in 33. Heberden rated the mortality in the island of Madeira at 1 in 50. To illustrate the beneficial effects of civilisation, the following details are very interesting. In Sweden, from the year 1754 to 1763, the mortality was 1 in 34; from 1820 to 1825, it was only 1 in 45. In Great Britain, from 1787 to 1789, it was 1 in 43. In France, in 1776, it was 1 in 25½.

“The medium of mortality throughout Europe was calculated many years ago at 1 in 36.”

I have said that the seasons have great influence on the bills of mortality. This was observed by the Father of Physic and all his eminent successors. It is admitted on all sides, that the greatest mortality in this country is in spring and in the month of April, and in July and August the number of deaths for the year are fewest.

A great deal will depend on abundance or famine, warmth and cold, and the prevalence of epidemics, but no certain results on mortality have as yet been arrived at in this country for the want of accurate registries.

It is highly gratifying to observe the decrease of mortality in all civilised countries during the last century, which is chiefly to be ascribed to the diffusion of knowledge,—the great source of the improvement of the moral and physical state of mankind. The comforts and happiness of mankind have been greatly augmented, the science of medicine vastly improved, and many formidable and destructive diseases completely prevented.

Scurvy, plague, small-pox, syphilis, rickets, scrofula, dysentery, miliary, spotted, and intermittent typhus fevers are greatly diminished, and some of them seldom noticed.

Great are the improvements which have been made in the healthfulness and comforts of the people of this country, but much remains to be done.

“There are,” says Mr. Robertson, the laborious author, from whose valuable work I have derived so much information, “many hurtful prejudices to be eradicated, especially in the domestic management of children and of the sick. There is great room for advance-

ment in the knowledge and treatment of diseases, but particularly in the cultivation of infantile medicine. Our medical police, too, if it be worthy of the name, is singularly defective; in this respect we are behind every other European state, a circumstance too well illustrated, among other proofs, by the continued prevalence of the small-pox in all our large towns, when it has for some years been wholly, or nearly, extinguished in most civilised countries. To these might be added grave defects of an economic kind, particularly in the parochial management of the poor, the administration of many of our public charities, and in the want of a general efficient system of education; what has been done in this latter respect being in a very great degree inadequate, at least in popular districts. We should hardly err in affirming, that the rate of infantile mortality will be found to be, *cæteris paribus*, in the ratio of the ignorance and improvidence of the population; a consideration which gives no little weight to the defects above mentioned."

It must be highly consoling to the philanthropic mind of this writer, that the legislature is at length about to remodel the medical police of this country, and to correct the manifold defects which he has so graphically described. But the evils he so graphically deplored were, in his opinion, capable of mitigations, or removal. He says, "It is consoling to reflect, that, where so much remains to be done in the great cause of human improvement and happiness, every one may do something. Whoever, in his particular sphere, assiduously inculcates sobriety, cleanliness, industry, and forethought, and is on the watch to correct hurtful prejudices and practices, especially in all that concerns the physical education of the young, performs duties which are not less important, because they are humble and unobtrusive. It certainly does not thence follow that their effects will be limited. The most effective virtues are those which operate at first in small circles: for, as he that is guilty of a moral injury, to even a single human being, can never calculate what may be the extent and duration of the evil to which he has given impulse; so he who is instrumental in improving one individual, however lowly that individual's condition, can as little estimate either the extent or duration of the benefit."—(*Observations on the Mortality and Physical Education of Children*. By John Robertson, M.R.C.S., Surgeon to the Manchester Lying-in Hospital. 1827.)

The next part of our subject is the consideration of the rules to be observed in the administration of therapeutics to infants.

I have been repeatedly solicited by the gentlemen who have attended these lectures to arrange a table of doses of medicines for children, but this cannot be done. The doses of remedies for adults are by no means determined, nor can they ever be rendered absolutely fixed, on account of the differences of temperament,

habit, and constitution. The effects of medicines vary according to age, sex, habit, temperament, in consequence of peculiarities of constitution, state of health, stage of disease, sensibility, climate, and season. Hence the great difficulty of determining or fixing the doses of medicines. There are some constitutions which suffer severely from the ordinary doses, while habit will enable us to increase the quantity to an extraordinary extent. The extract of hemlock has been given to the extent of an ounce daily in cancer, though the dose fixed in books is from 3 to 20 grains. It is also recorded, that nine fluid ounces of laudanum were taken daily without inducing sleep. Again, salivation has been caused by a grain of calomel, and another patient may take 500 without a similar effect. M. Cotteau saw a patient in the hospital at Tours, who was poisoned by the sixteenth part of a grain of tartarised antimony, though we now give large doses of this remedy in inflammation of the lungs with the best result.

The ancients were unacquainted with chemical analysis, and gave medicines composed of many ingredients, which they supposed to be simple, though the active principle was combined with a great quantity of useless matter.

Hippocrates employed simple remedies for the most part, which are now found to be compound by analysis, but he did not give a table of quantities.

Dioscorides was one of the first writers who attempted medical posology, or doses of medicines.

Galend did much for pharmacy, but his compound formulæ were very much increased by *Ætius*, *Rhazes*, *Avicenna*, *Averrhoes*, and others, who adopted the poly-pharmacy of the Egyptians and Arabians. Nevertheless the doses were not fixed, and were so uncertain as to be ridiculed by *Paracelsus*, whose gross prejudices, confident ignorance, and superstitious ideas led him to offer the most violent diatribes to them. The introduction of alchemy complicated pharmacy more than ever, and its progress was very slow, notwithstanding the advance of chemistry, since the time of *Stahl* and *Boerhaave*. It remains for the moderns, aided by chemistry and pharmacology, to perfect the art of dosing medicines.

It appears very easy at a first view to compose a medical posology, or exact table of doses, and that it ought to be sufficient for the attainment of this end, to compile from works on materia medica, practice of medicine, pharmacology, and selections of formulæ. But the doses of most medicines are very uncertain, they differ in different works, though most writers copy each other, and follow a blind routine. All of them adopt the table of *Juncker*, given by *Gaubius*, and there are many solid reasons to prove that this is liable to numerous exceptions. The vague appreciations of doses, mentioned by writers on materia medica, are of little use in practice, unless for

the guidance of students. Every country has its pharmacopœia, but not one contains the whole of the medicines in use, or the same doses. The difficulty of determining correct doses arises from the modifications which medicines undergo by age, sex, climate, &c. Some writers fix the dose of calomel from two to six grains, others from two to twenty, more advise it, under certain circumstances, in scruple doses. In general it is said, that a grain or two is sufficient for an infant, and that a larger quantity is hurtful; but should croup or hydrocephalus attack it, then the remedy has been urged to the amount of one hundred, or five hundred grains. I might adduce a vast number of similar illustrations, which show the inaccuracy of doses given in books. These in general are too small, but they are enormous if contrasted with the homœopathic quantities, with the hundredth thousandth millionth part of a grain, or drop of our medicines. While different ages, sexes, constitutions, idiosyncrasies, diseases, climates, and seasons exist, we must vary our doses of medicines. Posological tables cannot remove our difficulties. It is of little use to us to follow any one of them, except to those commencing the practice of medicine.

Juncker gives the following general rules for internal medicines, according to Gaubius. (*De Methodo Concinnandi Formulas Medicamentorum*, 1739):—

Fix the efficacious dose for a man of adult age at—	1	or 1 drachm
From 14 to 21 years	$\frac{2}{3}$	or 2 scruples
7 to 14	$\frac{1}{2}$	or half drachm
4 to 7	$\frac{1}{3}$	or 1 scruple
4 .	$\frac{1}{4}$	or 15 grains
3 .	$\frac{1}{6}$	or half scruple
2 .	$\frac{1}{8}$	or 8 grains
1 .	$\frac{1}{12}$	or 5 grains

This table is generally adopted by British writers on *Materia Medica*, while the French modify it in a slight degree.

MM. Bricheau, Chevallier, and Cottereau, in their work entitled, *L'Art de doser les Medicaments, selon des differens Ages, &c.*, 1829, propose the following posology. During 1 year, $\frac{1}{2}$ of the dose of adults, from 1 to 3, $\frac{1}{3}$, from 3 to 7, $\frac{1}{4}$, from 7 to 14, $\frac{1}{5}$, from 20 to 60 the dose for adults.

MM. Edwards and Vavasseur, in their *Nouveau Formulaire Pratique des Hopitaux, &c.*, 1834, fix the doses as follow:—

The dose for an adult	1
Under 1 year	$\frac{1}{12}$ to $\frac{1}{8}$
At 2 years	$\frac{1}{6}$
3 years	$\frac{1}{4}$
4 years	$\frac{1}{3}$
7 years	$\frac{1}{2}$
14 years	$\frac{1}{3}$
20 years	$\frac{1}{2}$
From 20 to 60 years	1

Above this age we follow the inverse gradation.

There are certain rules with regard to prescribing medicines which have been given with great precision by Gaubius, which I shall notice succinctly, as they are generally adopted, and must be referred to in infantile therapeutics.

A prudent physician prescribes nothing unless he can assign a satisfactory reason for doing so; hence he never acts at random, or until he has first accurately deduced the indication of treatment.

He first determines whether the diseases require medicines or not.

When he judges that the powers of nature are sufficient to effect a cure, that the disease is incurable, or that the cure would bring on a greater disease, he refrains from prescribing, lest he should either injure the patient, or uselessly torment him. *Medici, plus interdum quiete, quàm movendo et agendo, proficiunt.*

In many chronic and incurable cases, medicines are necessary, as it would be inhuman to desert the sick. This precaution is particular to be observed in the treatment of diseases of women and young girls.

If the indication commands the physician to act, he is to determine what he is to do, the means he is to employ, &c., which he will know by the established precepts of science.

He is always to bear in mind that the great and first end of his art is, that the cure is safe, quick, and agreeable (*Tutò, Cito, et Jucundè* *). Hence the most efficacious and appropriate remedies, not only in substance but in form, are to be chosen.

Those only whose action is safe and without danger are to be prescribed; sometimes, in desperate cases, dangerous remedies may be tried, but always with caution and judgment, and with the prediction of the uncertainty of the result.

So, new medicines not sufficiently explored are not to be ordered, when the same effects can be obtained by the aid of remedies which practice has sanctioned; the former must be used with great prudence, lest the prescribers incur censure.

We ought to avoid as much as possible all effete, obsolete and decomposable medicines, lest nausea should be produced, the effect frustrated, the sick uselessly fatigued, or dangerous accidents produced. It is therefore better to order medicines from the most celebrated shops; because, in such case, their sale is quicker, they are better prepared, and the integrity and skill of the apothecary commend them.

Those which are prepared with difficulty ought not to be prescribed unless we are cer-

* All Doctors in Medicine are sworn, on obtaining their degrees, to practise in this manner. The members of the College of Surgeons and Society of Apothecaries in this country are not.

tain of the honour and dexterity of the compounder.

We should be sparing in the use of expensive medicines, when cheaper ones are equally efficacious. The rich sometimes estimate the value of a remedy from its price, and the influence of the imagination is not to be despised.

Exotic medicines should not be preferred to indigenous, when both are equally efficacious, for these are less liable to adulterations.

Those whose names, tastes, and qualities are generally known, ought to be mixed with others, lest they frighten the sick, or diminish their confidence. Disagreeable, nauseous, and unpleasant medicines are to be avoided, or combined in small quantities with others, so that their properties may be disguised as much as possible. It is better not to exhibit any remedy at all than one which nature abhors; a rule that is to be particularly observed in cases of delicate women, infants, &c. The idiosyncrasy or peculiarity of the constitution should be known. Castor oil acts as a poison on some persons, as attested by Edwards and Vavasseur; and powder of crabs-eyes acted in the same manner, according to the testimony of Gaubius.

The physician should study simplicity in prescribing remedies, avoid bulk and number, for nature is the parent of simplicity.

It is, in general, objectionable to combine a great number of medicines in one compound, as they may decompose each other, and destroy their usual effects.

Whatever form of medicine the sick prefers, it should be prescribed. Some object to pills, powders, &c., others prefer them. There are some medicines which must be prescribed in a certain form, as calomel, which cannot be given in a thin fluid. Infants should not be ordered pills, bulky powders, or medicines with a strong odour or flavour, and all their medicines should be sweetened when this can be done.

The temperaments modify the progress and characters of diseases, and also medicines. Individuals who are strong and robust are generally of a sanguine temperament, and require bleeding and antiphlogistic treatment, which would be highly injurious to the delicate, irritable, and nervous, who are mostly of a lymphatic or nervous temperament, and who generally stand in need of tonics and antispasmodics. This rule, however, is far from being invariable.

Habit has also a great influence on the doses of medicines. Every one knows that opium may be gradually increased to an enormous quantity, and so with other medicines.

When a medicine does good, it ought to be continued until another is indicated, and it is bad to change it without reason. Some persons are constantly changing medicines before they have given them time to act, which gives rise to the impression that they do not understand the nature of the disease, and are trying experiments. In chronic and nervous cases,

it is sometimes necessary to change the appearance of the medicine.

"A physician should write his prescription legibly," says Gaubius, "for now-a-days the art of compounding medicines is entrusted to mere tyros, clerks, shopmen, and other incompetent persons; and hence there is great danger to the patient, and injury to the reputation of the physician."

In all cases before we prescribe, we should maturely consider the physiological and pathological condition of the alimentary canal, for a medicine which would be inoffensive at one time, might induce fatal consequences at another.

The doses of medicines are different, according to the power of each; and no fixed rule can be established with respect to them, for experience alone is our guide. The quantities must vary according to the effects they are intended to produce; and according to age, sex, temperament, climate, season, disease, &c. Tartarised antimony may be given as an emetic, diaphoretic, aperient, or nauseant. In all cases the dose must be proportioned to the age and strength of the patient. The body is more feeble in infancy, childhood, and adolescence, than at the adult age, and therefore the doses must differ to obtain the same effect in a man and in an infant. In all cases we should begin with a small or a medium dose, for it is much better to be obliged to repeat it, than to treat its excessive effects.

The constitution of woman is weaker than that of man, and the dose of medicine must be smaller for her, though it is not easy to fix the proportion. The smallest dose may excite great disturbance on account of the varied peculiarities of constitution. These can only be discovered by accident or time; but, when known, they should always be attended to.

Medicines ought to be administered when the stomach is empty; according to many, an hour before a repast, or when digestion is over. If taken immediately before food or drink their effects will be modified or nullified. The dose should be repeated before the effect of a former one has ceased, for otherwise we should be always commencing a cure, but never accomplishing it.

Those patients, who do not take their medicines regularly, are often astonished, when persuaded to do so, at the beneficial effects which are speedily produced. This is remarkable in cases of dyspepsia accompanied by constipation.

Every experienced practitioner is aware of the powerful effects of alterative medicine, or of small doses when taken regularly.

At our next meeting I shall describe those rules respecting therapeutics which apply to infants, and the best mode of prescribing for them. I shall also give the best formulæ for infantile diseases, and attempt to arrange a *Pharmacopœia Infantilis*.

CLINICAL LECTURES

ON THE
SURGICAL ANATOMY AND TREATMENT OF
THE UTERUS AND ITS APPENDAGES.

BY M. LISFRANC,

PRINCIPAL SURGEON OF THE HOSPITAL OF
LA PITIE, PARIS.

LECTURE III.

Diseases of the Uterus—General Considerations on the Symptoms and Treatment—Sub-Inflammation without Engorgement—Simple Hypertrophy of the Uterus—Simple Engorgement—Scirrhus Engorgement—Curableness of Scirrhus, &c., &c.

I SHALL finish my remarks on the diseases of the uterus, and their treatment, by dividing them into two parts: first, I shall speak of the sub-inflammations and engorgements of this organ, and afterwards of its scirrhus state; secondly, of the different ulcerations, vegetations, and different tumours to which this organ is liable.

I. *General Considerations.*—It has been frequently repeated, that diseases do not always betray themselves externally by symptoms equivalent to their severity: this general remark is more particularly applicable to affections of the uterus: this organ is frequently found excavated by deep ulcerations, and in such a state of degeneration, that all aid is useless; at which time the general health does not appear to be affected, the skin continues natural, the countenance blooming, and scarcely any external symptoms exist, which indicate disease about the organs of generation. There have been many patients in the ward of St. Augustin, who have presented horrid examples of this description. On the other hand, I have known women, with very slight disease, become thin, experience severe pains, and rapidly decay; demanding, at the commencement, a minute exploration of the indications of the disease, which, in general, begins in the following way:—

The female, from time to time, experiences a slight flooding, unattended by pains; at other times she suffers from leucorrhœa, which continues during the intervals of menstruation; the breasts become slightly tumefied, which symptom the patient very frequently believes to be an indication of health; she feels, after walking, or riding for a short distance in a carriage, pains about the loins; such great uneasiness is felt in the erect position, accompanied with twitchings in the lumbar region, that she is obliged to sit down; coitus is sometimes followed by a small sanguineous discharge, and determines slight pains, which either in a short time disappear altogether, or continue during one, two, or even three days.

The disease will sometimes stop here, and

spontaneously disappear; but more frequently the leucorrhœa increases, pains supervene, and are rarely felt about the uterus itself, but generally towards the broad and round ligaments, about the loins, and even extend to the posterior part of the thigh, and the back part of the foot, and which more than once have been mistaken for sciatica. They extend also towards the umbilical and lumbar regions, and frequently towards the rectum: they take place especially when the cervix uteri is carried backwards by a slight antiversion of the uterus, and presses on this intestine. The floodings return at shorter intervals, the tumefaction of the breasts subside, and they at length become atrophied; symptoms of gastro-enteritis appear, the patient becomes affected with intermittent fever, the accessions of which return more or less frequently, or there is nervous lassitude, with true hysterical paroxysms; the skin is parched and yellow, the digestive function becomes deranged, corpulency disappears, and the countenance changes.

It is seldom that the disease advances thus far, without some practitioner being consulted, after which the patient follows a certain and regular course. But at other times, as I have before said, though the general health appears good, the latent disease rapidly proceeds, and often very unexpectedly declares itself in an alarming manner. There is loss of appetite, severe pains, which cause restlessness and deprive the patient of all sleep, frequent floodings, the skin becomes dry and terrestrious, and in seven or eight days we see those females who, not long before, were so plump and ruddy, become in an anæmiated state. Lastly, a colliquative diarrhœa arrives to terminate the scene, which is protracted, rarely more than one or two months after the first appearance of the symptoms. Death will sometimes take place in twenty-four hours from perforation of the uterus and peritoneum.

I meet with at least twenty examples every year of affections of the uterus, which take this invidious character. I was called this year to visit the wife of a professional man. This lady, still young, was healthful and blooming, and might be considered as one of the finest women in Paris. Professor Moreau, who had already examined her, expressed his desire for my advice. On the introduction of the finger, I found the uterus reduced to a state of putrefaction, presenting one mass of foetid slough, into which it was easy to penetrate. There no longer existed any resource. It was necessary to inform the family of it, who imagined our prognosis to be unfavourable, and that we were ignorant of the disease. However, in a few months afterwards, they unfortunately became convinced of the accuracy of our judgment, by the patient falling a victim to this affection.

Let us suppose a practitioner is consulted, whatever are the affections revealed to him by

vaginal examination, or the speculum, there are different kinds of discharges. But if the patient complains of pain or weight about the pelvis after their cessation, which indicates uterine congestion, a revulsive bleeding, with an anodyne injection, frequently carries off, as if by enchantment, these pains.

If the pains, in place of following the menstruation, precede it, we must wait until the middle of the month. When the pains are independent of menstruation, and return in its intervals, we may repeat these bleedings two or three times in the month. The weakness resulting very frequently from the pains, which deprive the patient of appetite and sleep, far from being a contra-indication, requires bleeding as the best remedy.

There are certain idiosyncrasies which compel us to modify these precepts. Thus we have seen, in treating of proper remedies for the reproduction of menstruation, that, in some robust women, bleeding frequently promotes it immediately, whilst in others a revulsive bleeding will produce flooding. I am at the present time treating a lady, from whom taking a few ounces of blood produced this result. These are rare exceptions without doubt; nevertheless it is necessary to bear them in mind, since, in these instances, both general and local blood-letting should be rejected.

Some women, naturally nervous, cannot lose blood, without experiencing many disordered symptoms. We must then diminish the blood to the fourth of a palette (five ounces), and by this means occasionally succeed; but if, nevertheless, these symptoms supervene, it is necessary to renounce altogether the emissions of blood.

Putting aside these cases, bleeding, combined with narcotics, is a sure remedy for dispersing these pains;—I will say even it is the best of narcotics. This opinion is by no means new; for Stahl has observed, that in all cancerous affections, in which the veins became ruptured, the patients always found remarkable alleviation from it. You must have frequently seen me in the wards prescribe a revulsive blood-letting for twenty females, and at least fifteen have found much ease from it. Their pains cease for a time, of greater or less extent, unless some unforeseen circumstances, such as a moral affection or change of weather, arrive to counteract its effect. In this same ward, I kept alive for the space of two years a patient who was attacked with a very extensive disease of the uterus, in calming the pains much less with narcotics than by small bleedings, varied according to the strength of the patient, from a quarter of a palette to a palette.

When there exists an advanced disorganisation, accompanied with a discharge of a cancerous ichor, extremely small bleedings are indicated, for fear of favouring the absorption of this ichor. If the female be very debilitated, —if she present any indifference to surround-

ing objects,—a tendency to repose or stupor; in short, if there be reason to suspect a commencement of adynamia, bleeding might precipitate the fatal termination; and hence it is absolutely incumbent on you to abstain from its employment.

Cupping, blisters, &c.—I shall repeat here what I have previously said on local blood-letting. Employed in the acute stages, cupping and blisters only add to the congestion, which is plainly shown by their efficacy in the reproduction of the menses. Other counter-irritants merit the same reproach; and are scarcely adapted, even for the chronic state, either to disperse a simple congestion, unattended by pain, or to excite the vital properties in indurated tissues.

We place, then, the seton on a level with, and a little above, the anterior superior spine of the ileum, through the abdominal parietes, and the issue or moxa at the inferior and lateral part of the spinal column. Great precaution is necessary in the employment of these remedies, for, in some nervous women, the general irritation, which they produce, proves more injurious than beneficial.

Compression.—This is a useful remedy, but difficult in its application, and requires a thorough knowledge of its indication. Pessaries have been recommended in chronic engorgement of the uterus, into which the uterine neck protrudes, and the womb is compressed by its own weight; but, before the application, it is important to be certain that there exists neither inflammation of the vagina, bladder, or uterus, that would be aggravated by the presence of a foreign body. Such are the precautions necessary to bear in mind: if there exists pain it is necessary to abstain from it, and should the application of the pessary renew the pain and excite fever, it must immediately be withdrawn.

Beverages and the internal employment of medicines.—In the acute state we prescribe emollient drinks in abundance; in the chronic, decoctions of the *saponaria officinalis*, *scabiosa arvensis*, *rumex patientia*, or even extracts of these plants, provided they can be borne by the digestive organs. You can also in these cases have recourse to iodine, with advantage, conium, and other discutient preparations; but it is important, then, to watch, with the greatest care, the state of the digestive organs. Very frequently gastro-enteritis accompanies affections of the uterus, sometimes latent, but at others so severe as to obscure the diagnosis of the principal affection; it is here that discutients become dangerous. In how many instances have incurable patients, who might yet have lived a long time in comparative tranquillity, fallen victims to active preparations administered by empirics! I so much dread this complication of gastro-enteritis, that I even dare not administer the mildest laxatives by the mouth. In a number of cases, fearing to carry this apprehension to too great an extent, I have endeavoured to employ for ex-

ample, discutients in larger doses than ordinary, and in almost every case supervening symptoms have recalled me to my first reserve.

The employment of discutient frictions are less dangerous when of the hydriod. of potass or mercurial ointment, &c.; but it is important to wait always for the chronic state, for fear of aggravating the inflammation, if it still exists.

One word in conclusion concerning the exhibition of conium. We employ it as a discutient and narcotic; and for this purpose in general, its extract is preferred. Nothing hence is more treacherous, for in three-fourths of the druggists' shops these extracts of plants are composed of materials chiefly carbonaceous, and consequently possess no virtue; and it is well known, that M. Orfila has been able to swallow thirty grains with impunity. I prefer the powder, which I commence with at first in grain doses, doubling this quantity at the expiration of fifteen days, and subsequently increase it to as much as three or four grains. Sometimes it produces a slight inconvenience at the throat, and even occasions slight diarrhoea. It is then necessary to discontinue it, and endeavour above all things to prevent an attack of gastro-enteritis.

II. *Sub-inflammation without perceptible engorgement of the Uterus.*—You will be frequently consulted by women who experience darting pains about the region of the womb, in whom the least exercise, standing in the erect position, walking, or even riding in a carriage, fatigues excessively. Coitus is extremely painful; they complain of a sensation of smarting, accompanied with a burning heat within the pelvis, or, to use their own expression, *they feel as if they had fire in the womb*. There exists, besides, a turgescence of the abdomen, a sense of weight in the lumbar and iliac regions; even the efforts in the water-closet frequently cause pain. It appears to these women that they have some foreign body which incommodes them, and would, as it were, be expelled; nevertheless, there is neither prolapsus nor deviation of the uterus; the menstruation continues as ordinary, and there exists no other discharge; and the pains are sometimes remitting, but more frequently intermitting.

If, in this condition, we have recourse to vaginal examination, we find the neck a little more dilated than ordinary, but the consistence and volume of the uterus are not at all altered, neither does the application of the speculum point out any ulcerations about the neck, but its introduction, as well as that of the finger, produces pain, either at the same moment or shortly afterwards.

This affection is frequently considered as a simple result, from an idiosyncrasy of the patient, which are declared to be purely nervous, practitioners confine themselves to palliatives, or even abstain from these altogether, and the disease makes progress. But then, should this be only a nervous affection, is it

less urgent to combat it? Do we not frequently see, in some organs, a fluxation determined by nervous pains? I regard this state as a sub-inflammation without engorgement, and have not a moment in its treatment, but have recourse to the antiphlogistic and narcotic system, as I have just been stating to you.

III. *Hypertrophy.*—Simple hypertrophy of the uterus gives rise to the general symptoms already noticed; but other indications are necessary to recognise its existence, which are especially shown by the examination *per vaginam*. Thus we discover excessive heat about the internal surface of the vagina and uterine neck; the parts are, in general, very sensitive, much more so than in scirrhus engorgement; the uterus gives the same sensation to the finger as when it contains an embryo of four or six weeks; in fact, pregnancy, attracting the fluids towards this organ, determines in it a physiological hypertrophy, which may guide us in detecting a morbid hypertrophy. If you wish to obtain a comparative idea of the sensation by vaginal examination under these circumstances, you must remember that which is given in undegenerated lipoma; or by the breast of a young female who has suddenly expired; or, finally, that of a body slightly compressible, consistent, elastic, and of a spongy nature.

Engorgement may exist at the same time, both on the body and neck of the uterus, or separately on either of these parts, but not diffused so as to present little lumps, as in scirrhus; and, in every case, the weight of the organ is more or less augmented.

Here a question, sufficiently important, presents itself for discussion. The increased weight of the uterus fatigues, and elongates the broad ligaments, and these, participating in the diseased action of the uterus, have lost their elasticity, and consequently increase the weight of the organ. Hence it follows that every kind of engorgement, whatever may be its nature, is always accompanied with more or less prolapsus of the uterus, this prolapsus being the immediate effect of engorgement. This, then, is what is necessary for us to combat, and, in the majority of cases, by overcoming it you replace the uterus to its normal position, or very near it. I strongly urge this point;—therefore beg particularly to call your attention to it, the more so, as in ordinary practice practitioners act contrary, and treat solely the prolapsus, which they attribute to a relaxation of the broad ligaments; hence there may be a species of prolapsus without preceding engorgement, which I cannot absolutely deny, but these cases must be very rare, since the immense number of diseases of the uterus that I have treated, I have not yet met with one example.

The healthy uterus may otherwise be easily displaced from exertion of the female. Thus, when the speculum applied and kept in proper position merely by the thumb, in order to prevent its falling from its own gravity, and

the female bears down, the instrument becomes expelled with force, and the neck will sometimes descend to within an inch of the orifice of the vagina; consequently, in engorgements, it is essential to prevent the women from making efforts on going to the water-closet, and recourse must be had to clysters, since the prolapsus, already established, may continue through the influence of this pathological condition.

You must not confound simple hypertrophy of the uterus with a contrary condition of this organ. It is such an extreme softening of this tissue, that it sinks under the pressure of the finger, as an atheromatous tumour, or as the rind of a rotten apple; there no longer exists that spongy elastic tissue, giving the sensation of a fatty tumour, or breast. It is something of a pulsatous liquid substance; the tissues are converted beneath their envelopment into a sort of reddish brown pap, analogous to that which results from the friction of a cannon-ball. Sometimes this state is accompanied with superficial ulceration, at other times it exists without it. This is the latent cancer.

An accurate diagnosis is here of the highest importance, since simple hypertrophy does not require operation, but the latent cancer, rapid and fatal in its march, leaves no other resource than a complete extirpation of the affected parts; we may combine also to the differential symptoms already spoken of, that hypertrophy is generally of recent date, whilst, on the contrary, cancer is of long duration. Hypertrophy, too, frequently attacks the neck, and even the entire surface of the uterus, and cancer is limited for a long time to one spot of this organ. I shall urge this point on the uterine pathology the more, as I believe it to be essentially new, and moreover as the facts on which it has been founded, have been verified in this operating theatre, where I have frequently pointed out, and even placed in the hands of my hearers the anatomical parts, after the extirpation of the neck of the uterus, necrositated by cancer.

Simple hypertrophy may exist either with or without pain, consequently presenting two therapeutical indications. In the first, it is necessary to have recourse to antiphlogistics, total repose, emollient clysters nearly cold, injections also emollient of the same temperature, general baths, small bleedings from the arm, emollient beverage, &c. &c.; and, above all things, tranquillity of the diseased organs; the diet should consist of milk, vegetable, poultry, and fish; of course taking into consideration the habit and temperament of each individual.

This is simple treatment, but ought to be scrupulously and tenaciously observed. Diseases of the uterus are much more tedious to combat than those of all other organs; for, in the first place, you can do nothing the seven or eight days previous to the menses, or during the presence of this discharge, and

moreover this periodical congestion, although it physiologically influences in an unfavourable manner, increases the diseased and permanent action. The female and her medical attendant must therefore possess great patience, as the time necessary to effect a cure varies from one to three months. I will observe to you here, that you must not judge of the progress of cure by the state of the pains, for I have often seen the latter increase in proportion as the engorgements diminish. When hypertrophy is unaccompanied with pain, and there only remains a slight sense of uneasiness and weight within the pelvis, the disease has arrived at its chronic stage; here, also, it is necessary to employ general bleeding and cold-baths if they can be borne, ascending shower-baths, at first simple and afterwards medicinal.

It is in this case, that about fifteen leeches, applied around the uterine neck, are useful in hastening resolution, whilst recourse must be had to moderate exercise, simple or dry-cupping, and shower baths directed about the pelvis. Inasmuch as there is induration, bitter, but not discutient decoctions, may be prescribed. If excoriations be suspected, the speculum may be introduced without danger, since it is no longer counter-indicated by the presence of inflammation, and their cauterisation will prove a beneficial remedy.

In a word, the treatment should be altogether antiphlogistic in the first case, and in the second, stimulant and revulsive; the only precaution necessary to be taken, is to ascertain that the excitation does not pass beyond a certain limit, reproducing the chronic stage, and reclaiming a repetition of the antiphlogistics.

Simple engorgement—scirrhus engorgement.—I shall describe these two diseases together, inasmuch as the treatment is the same for both, and differential diagnosis is important only as regards the prognosis. In both cases vaginal examination reveals an uterus increased in size, either in totality, in its neck only, or in the body of this organ; its volume sometimes becomes enormously augmented, pain may be absent, or present itself equally severe in both instances, so that the destructive symptoms are limited to the following:—

1st. Simple engorgement is less hard, and presents on examination an uniform surface, whilst scirrhus offers little tumefied inequalities.

2nd. In scirrhus the mucous membrane of the neck is of a dull white colour, which I have never observed in simple engorgement.

3rd. Scirrhus is more slowly developed; thus, if the disease be only of two months' duration, particularly if it succeeds an abortion, natural labour, sudden suppression of the menses, I immediately know it is not of a scirrhus nature.

4th. Lastly, simple engorgement requires only a treatment of one month or six weeks, whilst scirrhus demands a much longer

time for its cure, even if the most appropriate remedies be administered.

The treatment varies according as the affection be acute, that is to say, accompanied with pains, smarting, and heat, or be arrived at its chronic stage. In the first, antiphlogistics must be employed; in the second, resolutes, and discutients administered, either externally or internally; should the disease prove obstinate, I have recourse to moxas, setons, and issues.

Is scirrhus really capable of being cured?—I myself have not the slightest doubt on this subject. Do we not see tumours of the breast and lymphatic ganglion, presenting all the characters of scirrhus, yield daily to an appropriate treatment? Hence these cures may be as readily obtained in uterine affections.

Doubtless it would be wrong to designate by the name of scirrhus every species of hard and unequal tumour, exciting pain only from the pressure and traction it exercises on the neighbouring parts. In fact, these indurations, these inequalities, accompanied even with vegetations and tubercles, are found in certain ulcers of the legs in old people, without implying the existence of cancer. Why, therefore, should not the same thing occur within the uterus? I confess, for a long time I participated in this error, but experience has now completely undeceived me. Six years since I condemned two females for an affection of the uterus, which presented all the above named characters. They are now perfectly cured, and enjoy an excellent state of health, and that which is more remarkable, is that nature alone effected the cure*.

Simple as well as scirrhus engorgement may be complicated with vegetations, ulcerations, &c. But, however, even when the diagnosis is obscure you must not be discouraged. I was sometime since consulted by two females labouring under an enormous uterine engorgement, accompanied with all these affections, in whom I ultimately succeeded in obtaining a radical cure.

SECRET SPECIFIC FOR SCROFULA.

“THERE are numbers of medical secrets which are very much boasted of, but as they are out of my line, I can form no opinion if they are really of value. I know of one medical secret, which is of great importance; and as its value has happened accidentally to come fully to my knowledge, I can speak very posi-

* These observations prove the great difficulty which exists in recognising the existence of scirrhus, and consequently in deciding in so positive a manner on the question of its curability.

tively upon it. It is a peculiar medicine and a mode of treatment, by which the king's evil, or scrofula, is effectually and certainly cured, so as never to break out again. My only child was so afflicted with scrofula, as to be in danger of becoming blind, and crippled in his limbs; I had the best advice, and followed it strictly, until I found that his case was quite out of the reach of any medical assistance in England; and then I took him to France, to try the skill of that school, but it proved no better, and I was quite in despair. Hearing of this secret treatment, which is practised by a Mrs. Anne Knight, at Dover-house, near Arundel, in Sussex, I made very full inquiries into its efficacy, and found that she possesses a certain specific for all scrofulous cases which are not of too long standing. As I felt very averse to submitting my child to any secret treatment, I took great pains previously to satisfy myself of the results of former cases. One was a woman, who had been cured thirty-six years ago by Mrs. Knight's husband, and has never had any return of illness; she has since married, and had two children, now grown up, and quite healthy; one of them has a large family, all very healthy children. Another woman was cured permanently by Mrs. Knight about twenty-eight years ago, and has since married, and had eleven children, of whom nine are living and grown up; they are all most healthy persons. A young man, now twenty-three years of age, was perfectly cured when a child of between three and four years old, and has ever since been quite strong. A young lady, about twenty-five, daughter of a very respectable man in London, was cured thirteen years ago, and has enjoyed very good health ever since. A young man was cured about the same time as the last, and is now twenty-five, a very fine healthy person. I visited the above individuals, and each one told me of several other cases of persons who had been patients of Mrs. Knight's at the same time with themselves, and were all, to their knowledge, cured permanently; and none could tell me of any instance of failure or relapse. Cases of cures of less standing, but equally certain and effectual, were very numerous. The marks and scars that I saw on these persons, showed that they had been severely afflicted; they all stated that they have now very strong health. My

child has been under Mrs. Knight's treatment more than a year, and is now nearly cured, and a number of other patients have, to my knowledge, been cured by Mrs. Knight, during the time I have attended her with my child. This valuable secret is in the sole possession of Mrs. Knight, who is arrived at an age when she is very likely to die without making any disclosure; and without the communication of that skill and discrimination which she possesses (and which I believe to be necessary for the successful practice), the mere disclosure of the secret of the medicines she uses, would be only a part of the advantage that would arise from complete instructions being given to all medical practitioners, none of whom can now cure the scrofula at all. The secret has been in her family for a great number of years; but she has given it perfection, by finding out how to apply the peculiar medicines more successfully than her predecessors. Mrs. Knight has not communicated it to her children, because they have not had a medical education, and they would not be allowed to practise by the College of Surgeons. She was herself in practice long before their Act of Parliament was passed, or else she would not be allowed by law to do what no physician knows how to do. I would recommend most strongly to Parliament to direct an inquiry respecting this secret, that when its value is proved, as I know it can be, a purchase may be made, and all medical men instructed in it, for the public benefit.

“ It would be a very good measure to reserve a portion of the revenue derived from the granting of patents, to accumulate and form a fund for the purchase of valuable secret inventions, like Mrs. Knight's, which are not likely to be disclosed by the inducement of any patent law, however complete; and also to reward individuals like Mr. Woolf, whose inventions have not come into use during the terms of their patent, but afterwards become of national importance.

• • • • •

“ Independently of the risk of such secrets being lost altogether, it is a great public loss to keep them locked up; for they cannot be extensively practised in secret, and the possessors must lay a very heavy tax on the little business they do execute in secret, with their own hands; also, the processes would be more likely to

get improved, if they were made publicly known; and new applications of the inventions would be made, which are not done whilst they are kept secret. Hence, I think, that public purchases of many inventions should always be contemplated, and a fund should be provided for that purpose. There are many other inventions where a secure patent would be preferable to attempting to preserve secrecy, although a patent, under our present law, is not preferable. It is scarcely possible to practise some secrets to a profitable extent, for any length of time, without losing them in the end; for the precautions that must be taken to ensure the secrecy, must tend to cramp and limit the exercise of the invention so much, that only a small proportion of the profit can be realised, that might be made by an open use of it, under a patent, if it were secured by law and for a long term. The medical secret of Mrs. Knight is an instance of the pernicious tendency of secrecy; for although the secret has been safely kept in that family for the greater part of a century, they have taken every possible precaution, and by that care have so limited their practice, as to have only gained a very common maintenance by it; they have refused to send out medicines, for fear of analysis, but stand by to see them taken; they have employed no assistants to compound the medicines; and hence ten or a dozen patients at a time are as many as can be treated with success. Mrs. Knight has rarely had so many as she could have managed, because the better class of persons have a great aversion to a secret mode of treatment by a woman, and will not go into the inquiries that I did, as to its merits. Mrs. Knight's family never put the secret into writing, for fear of accident, and hence it has always been subject to be lost by the sudden death of the possessor for the time. Hundreds of valuable lives have been lost by the scrofula, and most excessive misery endured, which might have been avoided, if this specific had been made generally known to all practitioners thirty years ago; and probably it might be applied to other uses in medicine.”—*Minutes of Evidence before Select Committee of the House of Commons on the law relative to Patents for Inventions. Printed June, 1829. Evidence of Mr. John Farey, Civil Engineer.*—p. 135.

Foreign Medicine.**HÔPITAL DES ENFANS MALADES.**

A General Review of the Clinical Lectures, delivered by M. BAUDELOCQUE during the three months of January February, and March, of the present year.

Ataxo-dynamic Fever cured by Tonics—Small-Pox succeeded by Scarlatina, with gangrenous Inflammation of the Throat—Acute articular Rheumatism rapidly cured without sanguine Evacuations—Pneumonia cured by Diaphoresis—Erythematous Laryngitis resembling Croup—Pneumo-Thorax—Diseased Liver resembling Phthisis Pulmonalis.

Ataxo-dynamic Fever—Exasperation of the Symptoms under the Influence of Antiphlogistics—Cure obtained by the Tonic Treatment.

MILLET, a boy, eight years of age, of weakly constitution, admitted on the 6th of March, was attacked, on the 26th of February, without any apparent cause, with pains in the head and abdomen, attended with general depression, moroseness, and loss of appetite, which symptoms soon assumed a severer character, and were followed by vomiting and delirium; epistaxis supervened, and the sense of hearing became considerably impaired. Leeches were applied over the epigastrium, and behind the ears, also blisters to the lower extremities, without any improvement to the state of the patient, but rather aggravation of the nervous symptoms after each application of leeches.

On the 7th of March, decubitus on the right side, flexion of the limbs, paleness and emaciation of the face, stupor, idiotish smile, vague delirium, screaming, incoherent answers, dryness of the nares, pupils slightly dilated and contractile, dryness of the tongue and lips, excessive thirst, abdomen collapsed and painful on pressure, constipation, involuntary discharge of urine, skin warm and dry, pulse 140, small; respiration 24 in a minute, râle sibilant.

Treatment.—Lemonade, laxatives, and emollient fomentations.

From this to the 12th, great amelioration of all the symptoms. Milk and broth allowed.

On the 18th, a relapse, brought on from imprudence; violent relaxation of the bowels; stools of a light yellow; delirium and intense fever. Sinapisms to the feet.

28th. Great improvement; intelligence restored; tongue moist; return of appetite. Nourishing diet.

From this time the symptoms gradually diminished, and the patient by the end of April had perfectly recovered.

The above case illustrates the impropriety of the strict use of antiphlogistics, especially of sanguineous evacuations in cases of low malignant fever. In this instance the symptoms were greatly aggravated by such treatment, and the patient reduced to the lowest stage of debility and emaciation. No sooner, however, was a strengthening plan adopted, than the patient progressively recovered.

Variola and Scarlatina supervening simultaneously in a Patient afflicted with Purpura Haemorrhagica—Gangrenous Inflammation of the Throat, unaccompanied with Pain—Death—Necropsy.

Basquyre, a boy of strong constitution, aged 13, was attacked in the middle of January last with purpura hæmorrhagica, which did not prevent him from pursuing his usual occupations, until the 8th of February, when he was seized on getting up in the morning with shiverings, succeeded by heat and fever, general uneasiness, cephalalgia, pains in the limbs, and in the lumbar region. In the course of the day bilious vomiting came on; and the next day dry cough, pain in the right side, and diarrhœa supervened.

On the 10th he came into the hospital with the following symptoms: decubitus on the back; great depression; redness and tumefaction of the face, eruption of papulæ over the body generally; scarlatine redness of the superior extremities; confluent patches of purpura on the neck, upper part of the trunk, and on the thighs; skin warm; pulse 124, regular and small; respiration 32; lips dry and chapped; breath foetid; thirst excessive; anorexia; no vomiting; three liquid and bloody evacuations by stool; incessant dry cough, without any cause detectible by auscultation or percussion.

(℞. Ipecacu. gr. xxiv., ant. tart. gr. j., to be taken at two doses. Mucilaginous drink,

emollient clysters, fever diet.) This medicine produced copious vomiting, and liquid alvine dejections.

12th. The variolous eruption has partially subsided; papulae of the face are scarcely visible; some vesicles upon the arms present distinctly the central depression. The scarlatina has assumed a violet hue; purpura unchanged; no pain in the abdomen; no nausea or vomiting; other symptoms much the same. Pulse 120; skin rather warm, and great depression. (Decoction of cinchona, four pints, two drachms of the julep of acetate of ammonia; broth diet.)

In the evening great agitation and violent delirium, lasting for the greater part of the night, then followed by excessive drowsiness.

On the 13th somnolency; cadaverous hue of the head, neck, and fore-arms; neither of the eruptions can be distinguished on any of these parts. Orthopnoea; respiration 60; voice extinct; breath horribly foetid; pulse small, thready, 184. The limbs still retain their warmth. (Blisters to the lower extremities.)

The patient gradually sinks, and in three hours falls a victim to this disease.

Necropsy.—The amygdalae, velum palati, pharynx, and internal surface of the larynx, covered with a layer of brownish sloughs, exhaling a gangrenous odour; the parts underneath are of a violet hue; around the glottis, and on the tongue are found some variolous pustules; the trachea and its ramifications contain a greyish fluid, also of a gangrenous smell, and their mucous membrane presents patches of ecchymosis. No remarkable appearance either in the lungs, pleurae, or heart. Mucous membrane of the stomach covered with a multitude of small ecchymoses, resembling the stains of purpura on the skin; small intestines contain a greenish fluid, several lumbrici, also a few patches of ecchymoses. The glands of Reyer are prominent, greyish, and reticulated; caecum and transverse arch of the colon contain hard fecal matter, and two or three ecchymotic patches about the size of a sixpence; liver of a light yellow colour, and bladder distended with a great quantity of urine mixed with blood; contents of the cranium healthy.

This boy was of a strong constitution, and from the account given by his relatives, no

clue could be obtained to the attack of purpura, which preceded the invasion of small-pox and scarlatina. The two latter presented nothing remarkable in their premonitory symptoms, but the progress of their eruption was very irregular. Such a combination of two febrile exanthemata is at all times extremely unfavourable, and proves almost invariably fatal in the Hôpital des Enfants, where it has repeatedly occurred. The gangrenous state of the throat could not be ascertained during life, owing to the impossibility of exploring that region, and the absence of all pain, even during external pressure. It cannot be attributed to the inflammation of the pharynx and larynx, but ought to be referred to the general state of the patient; it was of the same nature as those sloughs on the back of the sacrum, taking place during typhoid fevers, and that gangrene of the mouth which manifests itself in children who have been long confined in hospitals, like the Hôpital des Enfants. In the majority of cases it is not preceded by symptoms of phlegmasia; the typhoid state of this patient was quite independent of any alteration of structure in the brain, or digestive apparatus; the former was found after death to be in a normal state, and the ecchymosis in the latter invariably accompanies purpura haemorrhagica.

Acute Articular Rheumatism quickly subsiding without Sanguine Evacuations.

A boy, 14 years of age, who had previously enjoyed good health, was admitted on the 11th of March, complaining of a rheumatic affection of the left ankle and both knees, symptoms were heat of skin; pulse 120; tumefaction of the left foot without pain; swelling of both knees, with acute pain increased by pressure, or the slightest motion; tongue natural; thirst excessive; anorexia; pain in the right hypochondrium; bowels open for the first time for the last five days;—infusion of couch grass, (*chien-dent*), white looch, with two drachms of the white oxide of antimony, frictions of soothing embrocations to the painful parts;—fever diet.

Under this treatment the rheumatic affection continued, alternately attacking the muscles and joints of the limbs, but with less pain in the left hypochondrium, though with some diarrhoea. (The white oxide of antimony ex-

hibited in a mucilaginous vehicle, the looch being discontinued to ascertain which of the two the latter symptom is owing to.) On the 18th, diarrhoea diminished, but rheumatic symptoms the same. (The above treatment suspended, and the employment of warm-baths substituted.) From this date to the 24th, the pains and stiffness of the limbs gradually subsided; skin and pulse natural. Owing to change of weather on the 25th he had a slight relapse, after this the symptoms gradually diminished, and he was discharged from the hospital on the 10th of April quite well.

The antimony in this case afforded no alleviation, the disease was left to nature, and was cured rapidly. Medical men are too fond of the repeated employment of blood-letting in these affections, thereby causing, in many cases, protraction of convalescence, and not unfrequently giving rise to serous infiltrations. Sydenham, who was blamed by his contemporaries for a predilection in favour of blood-letting, recommends four bleedings at most in the acutest stage of rheumatism; yet many practitioners of the present day are not loth to open a vein six or seven times in the course of a few days for these affections. Brady, in a letter to his friend Sydenham, says "*In curatione rheumatismi frequentem phlebotomiam et largâ manu celebratam tanquam necessariam proposuisti. Quærerem ego an non rejectâ tam severâ et tam crudeli methodo, alia non humani sanguinis adeo prodiga, nec minùs certè inveniri possit.*"

GENERAL RULES FOR THE PRESERVATION OF HEALTH.

Air.—Exposure to cold and damp air is to be carefully avoided. Cold is the commonest cause of all diseases, and the greatest source of mortality.

Dress.—The clothing should be suited to the state of the weather, and always sufficient to keep the surface of the body moderately warm. Woollen or cotton dresses should be worn next the skin as a flannel waistcoat, drawers, and warm stockings. The habit of wearing this description of dress when once contracted must not be given up; but in warm weather a lighter description may be substituted.

Captain Parry's crew withstood intense cold

by warm clothing. The head should be kept cool, and therefore a heavy wig, or a warm night-cap ought not to be worn. When the head is kept too warm in infancy and advanced age, there is a determination of blood to it; which induces hydrocephalus, vertigo or giddiness, apoplexy, or paralysis.

The warmth of the feet and lower limbs directs the blood to these parts, and diminishes it in the head. Damp rooms, beds, linen, of course, are to be avoided. Constriction or pressure on the neck, chest, or abdomen, causes determination of blood to the head, impedes the breathing, predisposes to chest complaints and apoplexy*. Tight lacing is the cause of spinal distortions in women, and other deformities which endanger their own lives, and those of their infants during parturition.

Sleep.—The old proverb, "early to bed and early to rise," &c., is invaluable. Eight or nine hours' sleep are necessary in this case, notwithstanding the axiom of the once celebrated Salernian school, "*septem horas dormire sat est, juvenique senique.*" This is an error. Seven hours' sleep is too little for young or old.

Warm beds are extremely prejudicial to health on many accounts, and those which are hard or moderately elastic are preferable.

The head and shoulders should be moderately raised, and the best position is the right side, as it facilitates the passage of the contents of the stomach into the bowels, and affords free expansion to the lungs, a good respiration, and a sound sleep.

Either side is preferable to lying on the back. When a person of sedentary habit goes to sleep on the back, the respiration and circulation of the blood through the heart and arteries are impeded; the consequences of which will be disturbed sleep, sense of weight on the chest, called night-mare, unpleasant dreams, falling from precipices, &c., and determination of blood to the head, which always occurs when the breathing is embarrassed or interrupted.

* A German writer, named Fault, condemns breeches and trousers, on account of the pressure of their waistbands; and gravely advises mankind to substitute the Scotch kilt. The world, I think, will not agree to this.

Sleeping by day is contrary to nature and physiology, and hence such repose is disturbed and unrefreshing; it is not sweet, sound, and invigorating.

When an individual sleeps after dinner, he is nervous, debilitated, has taken too much food, or is predisposed to apoplexy.

Sleep is very much disturbed by late suppers, because digestion cannot be completed for two or three hours, the stomach is distended, the lungs cannot expand sufficiently, respiration is impeded, and the consequences described in the third last paragraph, night-mare, disturbed sleep, weariness next morning, lassitude and heaviness during the day, are experienced.

Loitering in bed after waking causes relaxation and debility.

Diet.—A strict observance of temperance establishes health, and prolongs life.

The plainest food, most simply prepared, is the best.

The red meats, as venison, beef, mutton, and hare are the most nutritious and easily digested, when the health is vigorous; but as they excite the pulse, and induce a slight degree of fever, they are improper for convalescents or valetudinarians. The white meats are less exciting, and hence called lighter, but they are not so nutritious as the former.

Fatty and oily aliments, as pork, geese, ducks, eels, fats, oils, cocoa, should be used sparingly, as they disagree with the nervous, bilious, and hypochondriacal.

Farinaceous aliment, as bread, potato, arrow-root, sago, tapioca, &c., are highly nutritious.

Mucilaginous aliments, as carrots, turnips, parsnips, cabbages, asparagus, afford very little nutriment, cause flatulence, and must be taken with pepper.

It is a popular and correct opinion, that aliments, which are relished by a healthy person, are generally wholesome.

The best mode of cooking meat is roasting; it is held that a pound of roast meat contains more nutriment than two pounds of boiled.

Fried or baked meats are objectionable.

Animal food should be masticated well, so as to mix it with the saliva, for if presented to the stomach half-chewed, it cannot be properly acted on by the gastric juice, and the result will be indigestion, flatulence, lowness of spirits, heaviness, tendency to sleep, &c.

When the teeth are bad, the meat should be cut very small, and broths, soups, and jellies substituted for it; as these contain much nutriment, and are presented in a state of semi-digestion, if I may use the term.

Ripe fruits are wholesome. Their excessive use causes numerous diseases in this country, and in the East and West Indies.

Drinks.—It is bad to drink freely at, or during dinner, as the gastric fluid will be too much diluted, and rendered unfit for dissolving the food in the stomach.

Water is the best drink, to which a glass of sherry or Madeira may be added. Toast water is also good.

Malt liquor is generally adulterated with stupefying drugs, and is injurious, unless in a small quantity. Home-brewed ale, the old *vinum Britannicum*, is a wholesome beverage. Table-beer may be used in moderation.

Spirits.—Whiskey, brandy, rum, and gin, &c., are useful in small quantities.

Wines.—Sherry, Madeira, or Port are the best, but others are good when relished. Two or three glasses at or during dinner are beneficial, by stimulating the stomach, and causing it to secrete gastric fluid more copiously. The French take wine at dinner, the English after dinner. The French are right.

Food should be taken to satiety, and masticated well.

It is bad to take exercise for two hours after a repast, as it impedes digestion.

Repletion, or over-feeding, is followed by heaviness, giddiness, lassitude, inclination to sleep, distension of the abdomen and flatulence.

Tea.—Black tea is a safe exhilarating beverage, but should not be taken too strong, or late in the evening. When used too freely, it causes nervousness, giddiness, want of sleep, trembling, agitation, anxiety, hypochondriasis, and melancholy. Tissot called a teapot, Pandora's box. Green tea is the most injurious.

Coffee, "the intellectual beverage," agrees with many much better than tea, and often relieves asthma when medicines fail. It may be used once a-day with advantage. The modern custom of taking tea or coffee shortly after dinner is good, as digestion is promoted by it. Late suppers are to be avoided, as they cause disturbed sleep, night-mare, predisposition to chest and head complaints. "Ut tibi somnus levis, sit tibi cœna brevis,"

is a good maxim,—a light supper ensures a tranquil repose.

Natural evacuations—Nature intends the bowels to act once in twenty-four hours, and that excrementitious matter should be of a deep yellow colour, and of proper consistence. When dark, black, green, white, or any other colour but the above mentioned, there is imperfect digestion, and a necessity for small doses of blue pill at night, and tonics during the day.

The urine should be evacuated whenever there is a desire, and always in the erect posture. The evacuation of the urine on either side or on the back is injurious, and may induce or aggravate diseases of the bladder and kidneys, which are the most distressing and fatal.

The urine may deposit sediments of various colours, red, white, black, green, yellow, &c. Of these the red is the commonest, it is composed of lithic acid, and is speedily corrected by soda water, magnesia, or lime water.

The white or yellowish-white sediment consists of phosphates or alkaline salts; and is corrected by proper doses of diluted sulphuric, nitric, or muriatic acids.

These sediments may be of frequent or rare occurrence, and may alternate very often. They are caused by deficient digestion, and may come on suddenly.

Exercise.—Exercise is as essential to health as air, food, or raiment; it circulates the blood throughout the whole body for the nourishment of all parts. Walking is the best mode of exercise. A sedentary life is the bane of millions, and the prolific source of a variety of diseases. It causes indigestion in all its Protean forms, lowness of spirits, confinement of the bowels, determination of blood to the organs in the head, chest, and abdomen. Exercise for an hour or two daily should be taken in the open air, or when the weather is unfavourable, in a chamber, by walking up and down. Exercise in the country, or that afforded by gardening, is recommended in preference to all other kinds, by physicians and poets, as we find in the works of Homer, Horace, and Virgil.

"Fortunatus est ille deos qui novit agrestes,
Panemque, Sylvanumque senem, nymphasque
suroris."

Cicero walked for an hour or two daily;

Hippocrates, Celsus, Galen, Pliny, and a host of others, attained considerable longevity by exercise, and especially by walking.

The intellectual faculties, the passions, the mind ought to be regulated so that there may be

"Mens sana in corpore sano."

The extremes of temperature in warm climates must be carefully avoided by Europeans. So also the free use of fruits, acids, &c., which induce bowel complaints, bilious attacks, spasms in the stomach and bowels, cholera, yellow fever, &c.

"In medio tutissimus ibis."

The observance of the foregoing rules will secure health, and leave little to be done by medicine.

"— Servare modum, finemque tueri,
Naturam sequi."

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY.

The annual competition for the Clinical Prizes in the medical department of this Institution was held on the 3rd of May, when the following gentlemen were declared the successful candidates by Dr. Graves:—

First Clinical Prize—Mr. King Ellison, of Liverpool.

Second Clinical Prize—Mr. James Johnson, of Lancaster.

Third Clinical Prize—Mr. Andrews, Belfast.

The Clinical Certificates were granted to Messrs. Berthon, Sullivan, Parker, Clarke, &c.

The public examination for the stethoscope prize, given by Dr. Stokes, was then proceeded with, when the following gentlemen appeared as candidates:—Messrs. Aldridge, Berthon, Clarke, Ellison, and Parkes.

On the termination of the examination, three of the candidates were found so nearly equal in answering, that it was determined to hold another examination, in order to award the prize. The three gentlemen, whose answering was so excellent, were Messrs. Ellison, Aldridge, and Berthon.

At the adjourned examination, held at Dr. Stokes's house, in which every stethoscopic sign, as well as those afforded by percussion and auscultation, were required, Mr. King Ellison, after a most arduous and close contest, obtained the prize.

PATENT MEDICINES AND NOSTRUMS.

There will be found in another part of this number a very singular extract from a volume of Parliamentary Papers, which is not within the reach of the general reader. We allude to the extract from the evidence of Mr. Farey before the Select Committee upon Patents in the year 1829. Mr. Farey is a gentleman well known as an eminent practical civil engineer, who is intimately acquainted with the law of patents. There are few unprofessional persons, to whose judgment and discrimination we would pay greater deference, even upon a medical subject. Some of our professional readers may perhaps have opportunities of investigating the nature of Mrs. Knight's treatment of scrofula, and her supposed specific for its cure, to whose beneficial effects Mr. Farey has borne testimony. Mr. Farey is, however, plainly mistaken in his notions of medical law, as it affects Mrs. Knight's practice.

How far it is possible or advisable to check the trade in medical secrets, or nostrums, and in patent medicines, is a question upon which some difference of opinion is entertained. It is a matter which must occupy the attention of the Parliamentary Committee, and we conceive it may be of some service to direct its attention, and that of the profession, to a document in which very material evidence upon patents in general and upon secrets in trade is to be found. We refer to the report already alluded to.

We shall extract from this interesting volume such portions as bear more immediately upon medicine.

It appears that the following parliamentary rewards have been given for medical discoveries since the year 1788:—

To Dr. Jenner, for promulgating his discoveries of the vaccine inoculation in 1802, a reward of 10,000*l.*, and in 1807 a further reward of 20,000*l.*; and to Dr. Smyth, for his discovery of the nitric fumigation to prevent the communication of contagion in 1819, the sum of 5,258*l.*

In the appendix of cases in the law courts, the first that relates to medicine is *Newbery against James* in 1816. This was the case of the celebrated fever powder of Dr. James, for which a patent was obtained in 1747. Dr. James, the grandfather of the defendant, made agreements with Mr. Newbery, the father of the plaintiff, in 1747 and 1755, that Dr. James, his executors, &c. should exclusively prepare the medicine for Mr. Newbery, his executors, &c., who should exclusively have the sale. Those agreements were to continue for an indefinite period, and had been acted upon till very lately. Upon an application to dissolve an injunction Lord Eldon observed:—“The patent for the fever powder is long expired, and it is required to enforce an agreement, by which the parties, independently of that patent, covenanted not to sell the patent article, except through each other's hands. The specification ought to enable all the world now to use the invention.” His Lordship dissolved the injunction.

The next case is *Williams against Williams*, which was an application to dissolve an injunction to restrain the defendants from divulging the secret composition of certain medicines for curing diseases of the eye, and from selling the medicines. In this case, the plaintiff stated that he was sole owner of the recipes of the medicine, and that he communicated the secret to

his son, and put him in possession of his stock, with the intention of taking him into partnership when of age. The son declined the partnership, and threatened to expose the secret. In answer to the allegations of his father, he stated that he had been instructed in it in early life by his mother, who had derived the secret from another, and had communicated it to her husband, the plaintiff. Lord Eldon observed, that so far as the injunction went to restrain the son from communicating the secret upon general principles, he did not think the Court ought to struggle to protect this sort of secret in medicine. The Court is bound to protect patentees, but that is because they have published their secrets. The injunction was dissolved.

The next case referred to is Canham against Jones, which was an application to restrain the defendant from making and selling a medicine called "Velno's Vegetable Syrup," of which the plaintiff claimed to be the sole proprietor: but an injunction was refused.

The only other case we have to cite from the appendix to complete our list is Savory against Price. In 1815 Savory obtained a patent for making artificial Seidlitz Water. The specification gave three distinct recipes for preparing the ingredients, and then directed two scruples of each of the three ingredients to be dissolved in half a pint of water, in order to produce the imitation of Seidlitz Water. It appeared in evidence, that the three recipes were only common processes for preparing Rochelle Salts, carbonate of soda, and tartaric acid; and those three substances being used as directed, constituted the patent Seidlitz Powder. The specification did not give any name to the ingredients. Upon an action for an infringement of the patent, Lord Tenterden (then Lord

Chief Justice Abbott) observed, that, by reading this specification, we are led to suppose a laborious process necessary to the production of the ingredients, when, in fact, we might go to any chemist's shop and buy the same things ready made. It was accordingly decided that the patent could not be supported.

Such is a concise account of all the cases we have found in the Appendix relating to medical secrets or patents. We shall resume this subject on another occasion.

STATE OF MEDICAL LAWS.

WE have received a petition of Dr. Haycraft to both houses of parliament, which makes out a very strong case of individual hardship arising out of the condition of the existing medical laws. In our last number we alluded to this gentleman's case. He is a dissenter, and, in consequence, disqualified from admission into the English Universities. He has, however, taken his medical degree at the University of Edinburgh; and, under the sanction of that degree, in common with many eminent and useful members of the profession, he practises in England. Conceiving himself libelled in his professional capacity, he endeavours to seek redress by exposing the calumny; but, at last, through the dread of that costly experiment of ascertaining "what is law," by the result of a trial, he is obliged to discontinue his action, because serious doubts are ascertained whether a degree from an University possessing one of the best medical schools in the empire is sufficient, in England, to support an action for an injury done to the reputation of its possessor as a physician.

We sympathise with Dr. Haycraft upon the uncertainty, and more than probable

injustice, of the law, without at all entering into the merits of his action. But the evil has been so generally felt and acknowledged, that it would be useless to devote more of our space to one instance of its oppressive operation.

**CHAIRS OF CHEMISTRY AND BOTANY
AT OXFORD.**

DR. DAUBENY, who has been for several years Professor of Chemistry at Oxford, has lately accepted the Botanical Chair at that University, in the place of a person who, in the words of the *Athenæum*, "unfortunately was not a botanist although a botanical professor; and, in whose hands the Chair became a nullity, and the botanic garden a wilderness." Such is the neglect with which this important branch of natural science has been treated at the first university of the kingdom, with its princely revenues and aristocratic students, that there is the utmost difficulty in raising funds for the renovation of the garden. Dr. Daubeny's well-known talents and liberality will undoubtedly do much for the restoration of botany in the University. But what a discredit to the arrogant pretensions of that learned body, to be compelled to disclose such humiliating details!

Of the Chair of Chemistry, and of the encouragement that science receives at the University, Dr. Daubeny will speak for himself.

"That entire devotion of mind to the pursuits of science which has enabled Rose, Mitscherlich, Stromeyer, and Thomson to reach the eminence upon which they stand, can hardly be looked to from the Professor in *this University*, who, unless he should be fortunate enough to possess some independent resources, must consent to regard the pursuit of chemistry

as a subordinate object to that of medical practice; seeing that the most assiduous discharge of his duties as professor, the most felicitous mode of expounding the truths of science in his capacity of lecturer, and even the most signal success as an experimentalist, can never, under the existing regulations, enable him to realise from his professorship *a pittance sufficient to meet even the most moderate views in life* *."

Reviews.

The Liverpool Medical Journal. Published monthly, under the Superintendence of an Association of Physicians and Surgeons, chiefly attached to the Medical Charities of Liverpool. No. II. June. Liverpool: W. Grapel. London: Henry Renshaw.

THE favourable opinion we expressed of the first number of this periodical was fully warranted by the practical value of its contents, and those of the present fasciculus afford further confirmation of the fact. The contributors to the work are gentlemen extensively engaged in the practice of the healing art; and their communications bear internal evidence of actual observation at the bed-side. The editors display integrity, independence, and high talent; and their journal, in point of practical original communications, is second to none in these countries. It confirms the opinions we have repeatedly avowed in our pages, that "sound chirurgical knowledge" is not confined to the monopolists of modern Babylon. The prosecution of the study of the healing art in different countries has enabled us to observe, that there are zealous and eminent cultivators of medicine in all nations, and in all sections of nations; and this conviction led us to publish provincial, French, Irish, and Scotch lectures, whilst our sagacious contemporaries, long before us in the field, could never even allude to them. They have, at the eleventh hour, however, imitated our

* An Inaugural Lecture on the study of Botany, &c. By Dr. Daubeny. London: 1834.

example in this respect; but, as yet, they have not condescended to notice the valuable periodical before us. We might expatiate on this theme, but compassion for imbecility restrains us. We allude to our hebdomadal rivals, not to our quarterly contemporaries, who, like ourselves, venerate science wherever it is to be found.

It would be unwise and impolitic on our parts to institute a comparison between the London Medical Journals and those published in such obscure places as Dublin, Edinburgh, and Liverpool; but truth and honesty compel us to remark, that we Babylonians stand in need of that co-operation, experience, and talent, which are portrayed in the pages published in distant and benighted parts of this kingdom. Here we have faction and party, jealousy, discord, and dissension, medical school against school, society against society, journal against journal,—opportunities the most extensive neglected in consequence of monopoly and incompetency,—all confusion. But we must pause, and turn to the work before us. We admire and esteem it, and anxiously wish that our hospital and dispensary brethren in this city would imitate the laudable example set to them. We are of opinion that every large city and town in the United Kingdom should contribute something to the advancement of medical science. Though we have expressed a most favourable judgment on our Liverpool contemporary, we must declare that, like every thing human, it is fallible. We shall give some examples.

Mr. Banner, our esteemed correspondent, gives, among many admirable and instructive clinical reports, the following, on which we must offer some remarks. In the first paper in the number before us, he details the following case of uterine hæmorrhage in the early months of gestation.

"CASE 2.—Mrs. —, aged 28, of delicate habit of body, married at the age of 19, had given birth to four living children, and had miscarried twice. She was delivered of her last child ten months previous to my visit; and was affected with a discharge of blood from the vagina, accompanied with slight, dull, aching pain in the back. She occasionally parted with small coagula: the discharge continued eleven days, sometimes more, sometimes less. It was on the 26th of

the month that it first commenced; she had then gone eight or nine days beyond the usual period for the catamenial discharge; this discharge had been regular for some months previous to this, but finding on the present occasion, that it was excessive in quantity, and attended with greater pain than usual, she became alarmed. On my first visit (on the second day), the patient was restless; complained of heat of skin, and thirst. The pulse was quick; the discharge florid, small in quantity, but constant. She had parted with several clots and shreds, which had been thrown away. She had been employed in her household affairs, and had not made any alteration in her mode of living. She was desired to remain in the recumbent position; febrifuge medicine was ordered, with acid drinks.

"Symptoms continued with little alteration, and the patient became gradually weaker, until the tenth day, when I was called to her at 4 o'clock in the morning. The hæmorrhage had increased; the pulse had become more irritable; the patient more restless. Forty minims of laudanum were given, and cold affusion applied. The discharge shortly diminished, and the patient became tranquil and slept a little.

"7 A.M.—The discharge continues, though slight; irritability much abated. A cold enema was administered, which remained with the patient some time, and the discharge ceased entirely for an hour, when it again recurred.

"Enemata of cold water were administered every two hours; they had now, however, lost the desired effect; and at the time of voiding them (always attended with considerable tenesmus) several small coagula were parted with, and the patient complained of feeling distress from their use. The pulse, though very weak, was regular. Cold application continued to the abdomen and thighs, and small quantities of soda water given, to allay the vomiting which had now commenced.

"On the morning of the eleventh day, the physician and surgeons who were in attendance, finding the patient weaker, the pulse small, quick, and irritable, the breathing slow, and countenance anxious, administered two grains of solid opium, and repeated it every

two hours: three doses were given; the effect was to increase the pulse in strength, and reduce it in frequency: the discharge continued to flow, however, though in small quantity. The ergot of rye was now given in scruple doses, and repeated every fifteen minutes, until five doses had been given. Injections of ice water were thrown into the vagina at intervals. The effect of the ergot of rye was to produce a very slight increased action in the uterus, and with it an increase of hæmorrhage, with distressing vomiting. At noon the pulse was scarcely perceptible; there was great listlessness, with stupor, (probably from the effects of the opium,) occasional hiccough, and almost constant vomiting. By the frequent administration of injections of ice water, the hæmorrhage again decreased; nevertheless the patient began to sink fast. Brandy in small quantities was given; notwithstanding, the pulse could be felt only at intervals; the breathing was oppressed; the eye half closed, and glassy; the urine was parted with involuntarily, and hiccough became a frequent symptom. In this extremity an examination, *per vaginam*, was determined on. The finger was introduced with great caution; the os uteri was found dilated sufficiently for its admission: from within the neck of the uterus was hanging a fine membrane, which was adherent; this was gently disengaged; the uterus slightly acted. Ice water was again injected, and afterwards a plug was introduced. During the whole of this operation the patient was unconscious; the pulse could not be felt at the wrist, and the breathing was only observed by an occasional gasp. It was considered as the only chance of saving the patient, that the operation of transfusion should be performed, which was accordingly done, and the patient recovered. From the time the membrane was removed, the hæmorrhage ceased.

"In the case just related, there is every reason to suppose, that, had the hand been introduced earlier, the cause of the hæmorrhage would have been removed, and much suffering prevented; and though transfusion was the immediate restorative, yet had the membrane remained as the exciting cause, the operation would have been useless, as hæmorrhage would have, in all probability, again returned. After the exciting cause has been

removed, and the usual means for stopping the hæmorrhage tried, without producing the desired effect, syncope is the result, which must be considered as the last effort of nature to stay the hæmorrhage. It is a symptom, generally speaking, that can be regulated. It occasionally happens, however, that all efforts are ineffectual, and the patient sinks, unless we have recourse to the only remaining chance, namely, the operation of transfusion. So great a chance does the operation of transfusion give, that in all cases of hæmorrhage (the exciting cause having been removed), where the patient dies without its having been had recourse to, I should not hesitate to say, that *every* means within the surgeon's power had not been tried."

Were we consulted in this case we should have acted differently. The discharge of coagula would have convinced us that the case was one of abortion. The menstrual fluid does not coagulate, the fluid in this case did; therefore it was not menstrual. What was it then?—We answer, blood, which, under the circumstances of the case, was caused by abortion. The discharge occurred nine days after the expected menstrual period; but the patient might have conceived three days after the last period; and the hæmorrhage, in our opinion, arose from an abortion of one, two, three, four, five, or six weeks of utero-gestation. Were we consulted, we should have acted thus:—As the evacuation was sanguineous, and not catamenial, and as the patient was so young, we should, in the first instance, have instituted a vaginal examination, ascertained the exact state of the os uteri, given sedatives, and plugged the vagina. This treatment would have been preventive, at all events. If the ovum had not been expelled, hæmorrhage, or abortion, would have been prevented; and if it had, which might have been the case, no evil could have resulted by removing the plug or tampon, at the expiration of twenty-four hours, and then cleansing the vagina and os uteri by an aluminous injection. The plug, if judiciously and properly applied, would have caused coagulum, and arrested the hæmorrhage.

We are informed, that on the morning of the eleventh day the physicians and surgeons exhibited opium very freely as a stimulant. This was good practice under the existing

circumstances, but would have been unnecessary were our plan of treatment adopted. The ergot of rye was given when the vital powers were reduced to the lowest ebb, and consequently could have produced little effect.

When the patient was dying, ice water was injected, and the plug introduced. Both were employed too late, in our humble judgment. Lastly, transfusion was resorted to, and saved the patient's life. We conscientiously believe, however, that this valuable operation need not have been performed, had the practice we have recommended been employed. It is said, that had the *hand* been introduced earlier, "the cause of the hæmorrhage would have been removed." The introduction of the hand, under such circumstances, appears to us unjustifiable. The patient could not have been pregnant more than five or six weeks at most; and the introduction of the hand into the vagina must have been productive of great pain, and, in fact, no more than a finger could have been passed into the os uteri at this stage of utero-gestation. We request our readers to consider the size of the gravid uterus at the fifth or sixth week of pregnancy, and of the vagina under such circumstances.

We have thrown down the glove to more celebrated obstetricians than our Liverpool contemporaries on this point of practice; and they honestly acknowledged its untenability.

Suppose a membrane had been developed in the os uteri, how, we beg to inquire, could it produce such profuse hæmorrhage? Let the scientific reader remember the pathology of adventitious membranes of this extent, and then answer our question.

We have differed, *toto cælo*, from the narrator of the preceding case, but we leave our profession to pronounce judgment. We are entitled to our opinion as well as Mr. Banner; and we consider ourselves fully as, indeed perhaps more, fallible than he is. Neither can we assent to the following conclusion:—

"Many remedies have been recommended, for the purpose of producing increased action in the uterus. The one at present most in use is the ergot of rye. That this medicine has the power of acting on the uterus, is proved by the assertions of many eminent individuals. Its effects, however, may be considered uncertain. I judge thus from the very contradictory reports

we have of its powers. In the few opportunities I have had of witnessing its effects, the operation was most unsatisfactory and uncertain, particularly in that state of uterus which exists in abortion. The fact, that since its introduction, as a means of producing increased action in the uterus, there has been a great increase in the number of still-born children, ought alone to make men pause ere they administer it. This mortality may be accounted for by the violent action of the uterus, brought on by its use, before the passages are sufficiently dilated for the expulsion. So long as there is slight action in the uterus, this remedy seems to increase it; but where all action has ceased, it is more than useless; for the nausea and vomiting which it generally produces have the most distressing effects, and generally tend to weaken the patient. Although the foetus, placenta, and membranes be thrown off entire, it sometimes happens that even here it is necessary to introduce the hand, and ascertain the cause of hæmorrhage."

We deny that the effects of genuine ergot of rye are uncertain. The fact is, that not one practitioner in a thousand is aware of the proper manner of keeping it. Eternal thanks to the London College of Physicians, who know nothing about it! their incomparable Pharmacopœia, which is super-excellent according to Dr. Paris, in his evidence at the House of Commons, is silent with respect to it! The result is, that the profession in general is unacquainted with its natural and medicinal effects; and hence the discrepant opinions on its value. We are, however, as convinced of its remedial effects as we are of opium or mercury; and we deny that its judicious use has increased the number of children. Neither can we assent to the doctrine, that "so long as there is slight action of the uterus this remedy seems to increase it, but where all action has ceased it is more than useless; for the nausea and vomiting which it generally produces have the most distressing effects, and generally tend to weaken the patient." It is well known that this remedy is now unfortunately used most criminally, and will irritate the unimpregnated as well as the gravid uterus, from the moment of conception.

In thus differing in opinion from Mr. Banner we intend him no disrespect, and we

beg to remind him, that doctors have disagreed from the beginning of the chapter. We leave the practical obstetricians to form their own conclusions. He quotes a case detailed by our able and talented friend, Dr. Malins, in support of his opinion, on which we must offer a comment.

Dr. Malin observes,—“I should be sorry to seem the too ready advocate of any kind of artificial interference in the practice of midwifery; but, as respects the introduction of the hand, multiplied experience has shown it to be generally effective; and, when cautiously and quietly performed, generally safe. The periods of gestation, also, to which it is applicable, should not be limited or absolutely defined, since more must evidently depend on the state of the genital passages, and the qualities of the operator, than on the number of months which the pregnancy has reached. The ill effects, attributed by Dr. Lee to this practice, may be considered to flow, not from its proper use, but from its abuse; either from recklessness and violence in its performance, or from subsequent neglect of means fitted to restore or preserve the tranquillity of the system.”

Our friend does not appear to us to be sufficiently precise in his premises. If he means that the hand can be introduced with safety, in the generality of cases, in the early months of pregnancy (before the sixth month for instance), we cannot at all agree with him. Perhaps he means into the vagina, if so, a primiparous woman will suffer severely, or even most of those who have no children. A moment's reflection on the state of the genitals, and the development of the gravid uterus during the early months of utero-gestation, must, we feel assured, convince our valued and learned friend of the validity of our opinion. We can assure him, that one of the most renowned obstetricians in this kingdom, who entertained a similar opinion, on which we offered comments similar to the above, has admitted their validity and justness. We follow nature and observation; but we offer our opinions with diffidence and respect for those who happen to differ from us.

Here we must terminate our notice of our Liverpool contemporary for the present, but shall resume it. Did we not entertain a high opinion of its contents, we should not have

expressed our sentiments so early or so freely. For both the gentlemen whose cases we have criticised, we entertain sincere respect; and if we differ from them with respect to the statements placed before us, it is with pain we do so; but, adopting the motto of the work in which they have written, which has long been our own, they will, we know, excuse us:

“*Amicus Socrates, amicus Plato, sed magis amica Veritas.*”

Both are well known as judicious and experienced practitioners; but, like all members of our and other learned professions, they cannot be surprised if some individuals differ with them in opinion.

HÔTEL DIEU.

Wound by Laceration of the Palm of the Right Hand — Phlegmonous Erysipelas of the Fore-Arm and Arm—Energetic Treatment—Amelioration.

BY M. DUPUYTREN.

JEAN BUTRUX, a printer, 48 years of age, of lymphatic temperament, had the palm of his hand lacerated by a fragment of a broken bottle. At the end of three days (21st April), having neglected the wound, the skin of the hand became red and erysipelatos. He was attacked with shivering, lassitude, anxiousness, followed by a pricking sensation in the part, and was at this time admitted into the Hôtel Dieu. The skin surrounding the wound was raised by the tumefaction of the subjacent cellular tissue, forming a hard and extensive tumour. The pain was pungent, and there was burning heat; pulse hard and frequent; cephalalgia, and considerable fever. M. Dupuytren proposed to obtain resolution, or, at all events, to diminish the abundance of the suppuration, to prevent the detachment of the skin, the formation of large abscesses, and termination by gangrene. A considerable number of leeches was applied, purgatives were exhibited, and a large blister placed over the erysipelas, which had already extended to the arm. These prompt and energetic measures gradually restored the arm to its natural size in two days; but the disease was too far advanced on the fore-arm; and, notwithstanding the active treatment employed, the phleg-

monous erysipelas terminated by suppuration. The surgeon then hastened to open the abscesses; he ordered the dressings to be frequently renewed, and the pus to be allowed to escape as soon as collected. He recommended methodical compression to be exerted over these parts, which as yet were in a state of engorgement, and some emollient decoction to be injected into the sinuosities of the abscesses. The fore-arm was kept in an elevated position. Besides this external treatment, acidulated drinks and emollient clysters were prescribed, and poultices applied to the affected part. From the beginning of the suppuration the fever was diminished, and the weakness which it had left behind had been combated by the tonic treatment. The same dressings were continued till the wounds were clean and covered with healthy granulations; after which light compresses with cerate were applied, and the wound kept covered as much as possible.

Fracture of the Ribs, with Laceration of the Lung, followed by Pneumonia—Cure.

BY M. SANSON,

Hivelin, coachman, 45 years of age, rather weakly constitution, was admitted on the 2nd of February. A coach had passed over the right side of his chest; at the moment of the accident he had fainted, and had remained in that state two hours on the public road, after which he was conveyed to an inn, and brought to himself by the usual remedies. On his admission into the hospital, the 3rd and 4th ribs of the right side were found fractured about their centre; respiration was short and frequent, producing acute pain about the region of the affected part; this was much increased by cough; countenance flushed and anxious; pulse full and frequent; no hæmoptysis since the accident. Copious blood-letting was had recourse to, resolute compresses *parti dolenti*, and a bandage properly tightened around the body. (Mucilaginous drink, fever diet.)

3rd. Much pain on respiration; face flushed; skin hot; much thirst; pulse not so full, 110. The patient could not bear auscultation, but dulness of sound was ascertained on the right side; twelve ounces of blood were extracted.

5th. Respiration short and frequent; skin

very hot; pulse small, hard, and quick; crepitous rattle at the seat of the fracture. Eight ounces of blood were taken immediately, and four to be repeated in the evening.

6th. Considerable hæmoptysis came on, mixed with sputa; tongue dry, much thirst; pulse small, from 120 to 130. Six ounces of blood were again taken from the arm.

15th. Several bleedings were necessary between the intervening days. Hæmoptysis gradually diminished; much sputa, indicating the second stage of pulmonary inflammation; pulse extremely small, but very rapid; life of the patient is almost despaired of. Blood-letting has been pushed as far as the system could bear it, and only one means remained to arrest the pneumonia, viz. tartarised antimony in large doses. Its efficacy, however, had only been ascertained in cases of spontaneous inflammation of the lung; its exhibition was thought to be of too doubtful result, and was therefore not resorted to.

M. Sanson confined himself to ordering a small quantity of chicken-broth. On the 19th the hæmoptysis had completely ceased; some diarrhoea supervened. 24th. Some amendment was perceived, and from this time to the 2nd of March, the symptoms gradually improved; the pain in the right side only occurred on coughing; the purulent sputa were very abundant; the appetite returned; and in the course of a fortnight the patient gained strength, and went out on the 24th quite cured but still rather weak.

Fracture of the Acromial End of the Clavicle.

A labourer, 33 years of age, of good constitution, came into this hospital on the 11th of April, for fracture of the clavicle, caused by falling and striking his right shoulder against a block of wood. Upon his admission, the signs of a transverse fracture were not to be easily detected, either by inspection or examination; but when the patient was told to carry his hand to his head, he could only accomplish it by bending the elbow, and leaning the head to the affected side. The integuments over the fracture were hardly raised by the point of the internal fragment, consequently there could be but little displacement. In the treatment of these fractures, says M. Dupuytren, Desault was the first to show, that it was not sufficient to draw

the external fragment backwards, but that it must also be raised, to be brought on a level with the internal one; he therefore constructed a bandage, which answers both these indications, and which is too well known to need any explanation; with its use five and twenty or thirty days are in most cases sufficient to produce consolidation. In this case it has already been applied eighteen days, but M. Dupuytren, having found that less consolidation than usual had taken place, has removed it, and applied it with greater care a second time.

EGYPTIAN SURGERY.

From a Report by CLOT BEY of Cairo.

Elephantiasis of the Scrotum.

THIS the author calls *œdema-sarca*, from Severin. He operated for this disease on five individuals: in one, the tumour weighed 80 pounds; the testicles being diseased were removed at the same time. In another, the tumour weighed 60 pounds, and was complicated with two hydroceles; the testicles, however, were preserved. The third was also complicated with two hydroceles, besides inguinal hernia of the left side: these cases, together with the fourth, were successful; but the fifth was in a state of marasmus, and had several urinary fistulæ. The operation terminated fatally.

BOOKS.

A Series of Anatomical Plates in Lithography, with References and Physiological Comments, illustrating the Structures of the Different Parts of the Human Body. Edited by JONES QUAIN, M.D., Professor of Anatomy in the University of London. Fasciculus XIII. Taylor.

The Principles and Practice of Obstetric Medicine, in a Series of Systematic Dissertations on Midwifery, and on the Diseases of Women and Children. Illustrated by numerous Plates. By DAVID D. DAVIS, M.D., Professor of Midwifery in the University of London. Part XXXII. Taylor.

The Surgical Anatomy of the Arteries of the Leg and Foot, being the continuation of Mr. Dermott's large plates, highly coloured, and the size of nature.

The plates are remarkably well executed, and the cheapest we have seen.

Ossa Humana; or the Bones of the Human Body, drawn from Nature. By R. B. CUMMING, Pupil of St. George's Hospital. Royal 4to. Two Plates. London, 1834. Sustenance.

The representations are accurate, and the lithographs well executed.

Physiognomy founded on Physiology, as applied to the various Countries, Professions, and Individuals: with an Appendix on the Bones at Hythe—the skulls of the ancient inhabitants of Britain, and its invaders. By ALEXANDER WALKER, formerly Lecturer on Anatomy and Physiology at Edinburgh. Illustrated by Engravings. 8vo. pp. 286. London, 1834. Smith, Elder, and Co.

A very curious and instructive work, which abounds with matter interesting to the reading part of the public.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE XCIII., DELIVERED APRIL 23, 1833.

GENTLEMEN,—*Wounds of the chest.*—When you consider the important organs contained in the chest, you would hardly suppose it possible for a bullet or a sword to pass across it without inflicting a mortal wound. Yet recoveries from injuries of this kind are frequent, and this notwithstanding the cases were complicated with a wound of the lungs. Nay, facts are recorded, which leave no doubt, that even wounds of the heart itself are not always fatal, balls having been found encysted in the substance of the heart after death from other causes, long after the receipt of the wound.

When in respiration the air passes alternately into and out of a wound in the parietes of the chest, you know, of course, that the weapon must have penetrated beyond the pleura costalis. In the expansion of the thorax by the muscles of inspiration, the air enters the wound; in its contraction by the muscles of expiration, the air is pressed out in a more or less forcible current. When the communication between the cavity of the pleura and the atmospheric air is free and ample, the lung generally collapses, unless prevented by adhesions; and the knowledge of this circumstance led to the belief, that if direct openings were made simultaneously into both cavities of the pleura, the patient would inevitably die of asphyxia produced by the collapse of both lungs. Experience proves, however, that this is not the fact, and that recoveries may follow wounds penetrating the two sides of the chest, even where the admission of air to the cavities of the pleura is free and direct. Now, gentlemen, there are three chief sources of danger in all examples of penetrating wounds of the chest.

1. You have the risk of profuse internal

hæmorrhage, by which the patient is sometimes destroyed at once; or by which he is more slowly cut off, generally in consequence of the extravasation in the pleura producing too much pressure on the lungs, or becoming combined with inflammation of those organs.

2. Then, gentlemen, other patients fall victims to inflammation within the chest, without any effusion of blood, though sometimes the inflammation is followed by abscess, or, as it is here called, *emphyema*.

3. Another cause of danger, gentlemen, where the lungs are wounded, is *emphysema*, or the inflation of the cellular tissue, sometimes of the greater part of it throughout the body, occasioned by the influence of the alternate expansion and contraction of the chest in respiration. The expansion, or act of inspiration, draws the air first from the breach in the lung into the cavity of the pleura, and thence it is propelled into the cellular membrane adjoining the wound in the side, by the diminution in the capacity of the chest in each expiration. In other words, each inspiration draws it out of the rent in the lung into the cavity of the pleura, and each expiration pumps or compresses it out of that cavity into the cellular tissue, for it cannot return into the air cells, on account of their being already full of air themselves.

The symptoms of a wound of the lungs are, bloody expectoration immediately after the receipt of the injury, great difficulty of breathing, a feeling of suffocation, and a sudden alteration of the countenance, in which you will remark paleness and anxiety. Here the immediate danger is either from the quantity of blood, withdrawn from the circulation by internal hæmorrhage, or from the passage of that fluid into the bronchiæ and air-cells of the lungs, or into the cavity of the pleura, so as to cause suffocation. Hence wounds of the root or upper part of the lungs are always the most dangerous.

With regard to the treatment of wounds of the chest, I may observe, that it is a general rule to close all such wounds without delay. You ought, however, to extract any splinters of a broken rib, a ball, a portion of the cl

or any other extraneous substance which lie near the surface, and can be easily reached without too much irritation of the parts. With respect to a wounded intercostal artery, all the best modern practitioners disapprove of the introduction of various instruments and contrivances into the wound or chest for the suppression of the bleeding. Dr. Hennen had heard of examples, in which the intercostal artery was taken up with a tenaculum. But supposing this were not practicable, I believe that less danger would arise from closing the wound and applying a compress over it, than from the introduction of extraneous substances round or within the rib. I have lately been attending a young gentleman, one of whose intercostal arteries was wounded by a small knife. The result was a prodigious effusion of blood under the muscles of the back, followed by large collections of matter, and very urgent danger; but in the end the boy recovered. No attempt was made to secure the vessel. About eight ounces of blood flowed out of the orifice of the wound directly after the accident; the outward hæmorrhage then ceased, but the blood accumulated in the cellular tissue; great swelling ensued, and in about eight days such a quantity of matter and putrid blood was suddenly discharged from the external wound, that the patient lay in a kind of pond, extending from his feet to his neck. Incisions were occasionally practised to facilitate the exit of the matter. It was some months before the discharge ceased, and the wound closed. Leeches and venesection were also freely employed in the early and inflammatory stage.

In all penetrating wounds of the chest, and especially those extending into the lungs, the free use of the lancet is the only thing which can be depended upon in the beginning of the treatment. It is by this means that internal hæmorrhage is to be checked; and the inflammation of the lungs is to be prevented or subdued. Here, as in certain injuries of the head, moderate bleeding will not suffice. You may perhaps be required to bleed the patient more than once a-day for six or eight days in succession. The first bleeding should be copious; and, if the patient faint, you should not give him cordials, but allow him to revive gradually without them.

When the oppression of breathing returns, and the pulse rises, accompanied by pain in the chest, and spitting of blood, venesection should be performed again; and thus the lancet is to be used as often as the state of the circulation, the pain and oppression of breathing, or other circumstances call for it. If you neglect this rule, you are certain of losing the patient.

When the paroxysms of pain, the sense of suffocation, and the internal hæmorrhage are lessened, but the cough is severe, you may prescribe digitalis, or hyoscyamus, with small doses of the acetate of morphia, and saline medicines.

When much cough and pain in the chest continue, after bleeding has been carried as far as practicable, a blister may often be applied to the chest with great benefit; and, perhaps, leeches, or cupping, might yet be ventured upon, though venesection itself were not any longer proper.

When matter forms in the cavity of the pleura, after a wound of the chest, constituting empyema, or when the extravasation of blood in the chest causes urgent danger by its pressure, the indication is to make an outlet for the discharge of such fluids; but, if the wound should not be closed, you ought to avail yourselves of the opening already existing for this purpose; and, with this view, direct the patient to lie in a posture that will render the wound depending.

In former days, gentlemen, when blood was extravasated in the chest, surgeons used to make themselves particularly officious about its evacuation, sometimes using tubes and syringes for the purpose. But, at present, we never hear of such schemes in actual practice, to which they are little suited. This part of surgery, gentlemen, may sometimes be attended with a great deal of perplexity; for you have two dangers to contend against,—one is that of letting the patient die of suffocation from the pressure of the blood on the lungs and diaphragm, if no opening be made for its discharge; the other is that of seeing him fall a victim to continued hæmorrhage if such opening be made. I believe, however, that the experience of all the best army surgeons, who are the most experienced judges of this subject, will justify me in saying, that you will generally act with most prudence when you do not hastily adopt schemes and contrivances for discharging blood from the chest, but rely upon rigorous antiphlogistic treatment. The diagnosis also is rarely so clear, with regard to an extravasation of blood, as to justify the performance of an operation for its evacuation. At all events, you should not be in too great a hurry to make an opening in the chest, but give nature an opportunity of doing her best, under the assistance of the treatment which I have advised.

Sometimes wounds of the chest are complicated with protrusion of a portion of the lungs: one such case was brought to me at Brussels after the battle of Waterloo. The protruded piece of lung was of a long, narrow, tongue-like form, and severely contused. The wound had been made with a lance. I thought at first of cutting the protrusion off, but the bleeding made a ligature more safe. The patient, I believe, did not ultimately recover.

Emphysema, or the inflation of the general cellular tissue, is more frequent after a fractured rib with wounded lung, than after a common penetrating wound of the chest, because the air has no outlet, the skin being entire.

The symptoms of emphysema are great oppression of the breathing, inability to lie

down, or a preference to an upright or sitting posture; a colourless, elastic, crackling tumour, beginning near the wound or fractured rib; and often extending with great rapidity over the body, so as to cause sometimes an enormous distension of the cellular tissue of every part and region. The chief cause of danger, however, is not this diffusion of air in the common cellular membrane, but its insinuation into the interlobular cellular tissue of the lungs, and its accumulation in the cavity of the pleura, two circumstances causing a perilous obstruction of the function of respiration. Emphysema is also frequently combined with the danger depending upon inflammation, effusion of blood, or lodgment of foreign bodies in the chest.

The treatment varies according to the degree of emphysema, and the urgency of the symptoms arising from it. In slight cases, it may be sufficient to make a few punctures, in the swelling, near the wound, or over the broken part of the rib. These will prevent the air from extending itself widely; but, as I have said, this is not the chief danger. The risk proceeds from the accumulation of air in the cavity of the pleura, a state indicated by a metallic tinkling sound, compared to the dropping of shot into a porcelain basin; and, therefore, when small scarifications do not give relief, and there is reason to believe that air is confined in the chest, you should make a deeper and freer incision over the broken part of the rib, or enlarge the original wound, and puncture the pleura costalis.

Slight scarifications and a bandage round the chest will tend to prevent the increase of emphysema in the common cellular membrane: and may indeed be of important utility in hindering its extension into this texture so far as to reach the interlobular cellular substance of the lungs. Yet, in more aggravated cases, I believe with Baron Dupuytren, they are inefficient means, and that the pressure of the bandage really makes the state of the breathing worse. In urgent or rapidly increasing cases, therefore, I believe, the most prudent plan is to make an incision, and then cautiously puncture the pleura costalis.

In cases of emphysema, the place for the incision and puncture is determined by the fracture, or original wound, where the air first escapes from the chest; but, when the intention is to let out blood, water, or purulent matter, you divide the integuments over the space between the sixth and seventh ribs, where the indigitations of the serratus major anticus meet those of the obliquus externus, and cautiously puncture the pleura.

No surgeons of common sense ever think of plunging a trocar into the chest, or performing paracentesis; a proceeding so much spoken of in old works on surgery. When you make an incision, be sure to let it be away from the lower edge of the rib, where the chief branch of the intercostal artery runs.

Diseases of the Breast.—Gentlemen, I believe, we have no better classification of the diseases of the breast, than that adopted by Sir Astley Cooper; namely,

First, into diseases, which are *the result of common inflammation*, whether it be *acute*, or *chronic*.

Secondly, into complaints which arise from *peculiar or specific action*, but which are *not malignant*, and *do not contaminate other structures*.

Thirdly, into those, which not only consist in *local, malignant, and specific actions*, but which are *connected with a peculiar and unhealthy state of the constitution*, and affect with similar disease, besides the part originally attacked, others in the neighbourhood, and even sometimes remote parts.

The first class of diseases comprehends:

1. *Acute inflammation* of the breast, and the *milk abscess*.

2. *Chronic inflammation*, terminating at length in *suppuration*.

3. The *lacteal tumour*, so called by Sir Astley Cooper, on account of its arising from obstruction of one of the lactiferous tubes, as an effect of chronic inflammation. I will first speak, gentlemen,

Of Acute Inflammation and Milk Abscess.

—You know perfectly well that women, during the period of suckling, are particularly liable to inflammation and suppuration of the breast, whence the term *milk abscess*. The inflammation is of the phlegmonous kind, exhibiting all its usual characters; but, on account of the sensitive nature of the part, and the envelopment of it in a dense cellular or fascial membrane that does not readily yield to inflammatory swelling, the suffering is uncommonly severe. A solid swelling is produced, succeeded by a blush of inflammation on its surface, and at length a prominence and smoothness in one particular situation, where you will be able to feel the fluctuation of matter.

The most frequent cause of the *milk abscess* is the great determination of blood to the breast each time the child is about to suck, by nurses called the *draught*, combined with the mechanical irritation, to which the part is continually subjected. The origin of such abscesses is sometimes promoted by the child not being put to the breast soon enough after birth; consequently the breast becomes too full; and this state, influenced by the stimulating diet often pressed upon mothers by nurses, soon ends in acute inflammation.

If you meet with acute inflammation of the breast in its early stage, you may sometimes bring about resolution by employing cold evaporating lotions, leeches, and purgative medicines. Amongst the causes of this complaint, I have mentioned the mechanical irritation and disturbance of the breast in suckling. Hence, I always advise the mother not to allow the child to suck the inflamed breast; and, if it be necessary to draw the milk from it, re-

commend the use of a glass tube made for the purpose.

When an abscess cannot be prevented from forming, cold applications are to be discontinued, and emollient poultices and poppyhead fomentations substituted for them.

With respect to the question of opening the abscess, I may observe, that if the collection of matter be superficial, not attended with extreme pain, and quick in its progress to the surface, you may let it burst of itself; but when the abscess is deep, its progress tedious, and the pain severe, accompanied by much fever, the matter should be let out. However, even under these circumstances, it is rarely judged advisable to cut through a great thickness of parts, or to attempt to make an opening unless the fluctuation of the matter can be plainly felt.

Gentlemen, you will meet with some cases which are exceedingly obstinate, in consequence of several abscesses following one another in succession. Here the administration of opium and the sulphate of quinine will be found beneficial; and when a deep-seated abscess leads to the formation of sinuses in various directions, which continue to discharge matter for a long time, if they cannot be healed by pressure, you may follow Sir Astley Cooper's plan, which is, to inject them with a lotion of rose water, with every ounce of which two or three drops of concentrated sulphuric acid are blended, and apply the same lotion to the surface. Mr. Hey, of Leeds, was an advocate for laying open all sinuses of this kind; a painful practice, scarcely ever requisite, as far as my experience enables me to judge.

Chronic Abscesses of the Breast, I believe, occur chiefly in scrofulous constitutions, and are much less frequent than acute milk abscesses. The matter ought to be let out, and an attempt made to improve the general health by some of the plans mentioned in the consideration of scrofula. The state of the uterine functions should always be inquired into. They will often be found to be disordered, and then aloetic and steel medicines are indicated.

The *Lacteal Swelling*, as it is named by Sir Astley Cooper, is confined to the nipple, and consists of a large collection of milk in one of the lactiferous tubes, the aperture of which has been stopped up by chronic inflammation. It is a disease analogous to ranula. The swelling presents a distinct fluctuation; the cutaneous veins are large; but the colour of the skin is not changed. If a slight puncture be made it soon heals, and another accumulation takes place; or, if a small ulcerated opening form, a little way from the nipple, it continues during the period of suckling, and the milk, instead of passing into the child's mouth, is lost.

With regard to the treatment, gentlemen, a puncture of moderate size will suffice, if the child be weaned; if not, a larger opening must be made, so as to let the milk escape while the child is sucking, until the secretion of milk

ceases, or the child is weaned. This is the advice given by Sir Astley Cooper.

I come now to complaints of the breast, arising from peculiar or specific action, but not malignant. Of this nature are the

Hydatid Tumours, as they are named by Sir Astley Cooper, and of which he gives an account of several varieties. Some surgeons prefer the name of *cystic sarcoma*, because the expression *hydatid* would lead us to suppose that the disease really contained, not adherent cysts, but detached globular ones, endowed with separate vitality, independent of the texture in which they are formed.

This cystic sarcoma I have already noticed with other sarcomatous tumours. It is characterised by a tendency to increase to a considerable size; but it is not prone to malignant change, nor does it occasion any inconvenience, except what proceeds from its bulk. At first, it feels entirely solid, but after a time a fluctuation can be distinguished at certain points. The tumour is very moveable and pendulous. Sometimes the cysts ulcerate, discharge a serous fluid, and then heal, or even become obliterated. No local applications are of any service. If there be only one large cyst, and it be punctured, sometimes it will not fill again. The only reason for removing this kind of disease, when it becomes large, is to relieve the patient from the annoyance produced by its bulk. All the swollen and indurated parts must be taken away, for if you leave any small cysts behind, the disease will recur. The glands in the axilla are either free from disease, or only enlarged by irritation.

Then, gentlemen, you will also meet with *swellings of the breast consisting of globular hydatids*. They should have an incision made in them, and the bag extracted, after which the part will heal. The disease is characterised by a central fluctuation, a solid circumference, and freedom from tenderness on pressure. The disease is quite of an innocent nature.

The *Chronic Mammary Tumour*, as it is named by Sir Astley Cooper, is another case meriting your earnest attention. The substance of the female breast is liable to a slow kind of induration,—a swelling that grows from its surface rather than from its interior, and therefore seems to be superficial, except when it grows from the posterior surface of the breast. It is exceedingly moveable; not buried in the mammary gland, but only connected to its surface; not generally painful or tender when touched; its growth is slow; and its weight seldom more than from one to four ounces. It is not malignant, and often remains stationary for years, and then disperses. The disease seldom occurs in persons after the age of thirty.

The tumour, when taken out and examined, is lobulated, and at first view something like the mammary gland itself: this tumour has a cyst. The cause of the chronic mammary

tumour is generally sympathy of the breast with the uterus, producing great determination of blood to the part, but blows and the pressure of stays may sometimes excite it.

Alterative medicines may be useful. When the digestive functions are deranged give the compound calomel pill at night, with the infusion of calumba and rhubarb and carbonate of soda twice a-day. When the uterine functions are disordered, you may prescribe small doses of the blue pill, with extract of colocynth and steel medicines.

The tumour may also be dispersed by the internal and external use of iodine. The emplastrum ammoniaci cum hydrargyro is a common application.

The tumour does not require to be extirpated, nor, as Sir Astley Cooper observes, is it any impediment to matrimony. for, in fact, pregnancy and suckling rarely fail to make it disappear.

A *scrofulous swelling of the breast* is occasionally seen in young women, who have enlarged lymphatic glands under the jaw. In general, there is only one tumour, and it is exceedingly indolent. There is no disposition to malignancy, and of course it would be improper to have recourse to extirpation. The treatment is like that of scrofulous diseases in general.

I next request your attention to the *irritable tumour of the breast*. The breast is sometimes the seat of severe pain without any distinct or perceptible swelling. Such an affection might be called *neuralgia* of the breast, but occasionally you will find that, besides excessive pain in the part, there is also a tumour, composed of a structure unlike that of the gland itself, and which therefore appears to be a specific growth. When the glandular structure is the seat of it, one or more of its lobes become exquisitely tender, and, if handled, the pain will sometimes continue for several hours, extending to the shoulder, axilla, down the arm, and even to the side of the body.

When the pain is most severe, which is often the case prior to menstruation, the stomach frequently sympathises, and the patient is troubled with vomiting.

The *irritable tumour* is most common between the ages of 16 and 30.

Sometimes you will notice a distinct circumscribed tumour, highly sensitive to the touch, acutely painful at intervals, more especially just before menstruation, very moveable, often not larger than a pea, and rarely exceeding the size of a marble.

Although the disease may continue for years, it varies but little in size, hardly ever suppurates, but occasionally disappears of itself. In the account of sarcomatous tumours I have already noticed this disease under the name of *painful tubercle*, as affecting other parts.

The tumour, when taken out and examined, is found to be composed of a solid semi-trans-

parent substance, with fibres interwoven with it; but, according to Sir A. Cooper, no large filaments of a nerve can be traced into it.

Equal parts of soap cerate and extract of belladonna may be applied, or a bread poultice made with a solution of the same extract. Or the part may be protected with a piece of oil skin, or hare skin. You may likewise apply leeches during the violence of the pain.

As internal remedies, you may try calomel with opium, and henlock with purgatives. If the menstrual secretion should be interrupted, you may prescribe the *mistura ferri comp.* combined with aloes.

What has been termed the *ecchymosis, discolouration of the breast*, and is a morbid change, sometimes occurring in young women at the time of menstruation, preceded by severe pain in the breast and arm. The extravasation of blood makes its appearance as a large spot, with smaller and less conspicuous ones in other places. In general, after menstruation, it gradually disappears.

According to Sir Astley Cooper's views, the indications are

1. To render the menstrual discharge more regular than it often is in these cases, by means of steel medicines, and to support the strength with sulphate of quinine given with *infus. rosæ comp.*

The best local application is the *liq. ammon. acet.* with spirit of wine, five ounces of the former to one of the latter.

With respect to the *third class of diseases* of the breast, or the *malignant*, it comprises cancer and fungus hæmatodes, the nature of which I have already explained in former lectures.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XXIII.

Diseases of the Nervous System—Causes of Variation of Symptoms—Organic and Functional Diseases—Neuroses—Question of Molecular Change in the Nervous Centres—Application of the Doctrine of Isomerism—Difficulties in distinguishing Arachnitis from Encephalitis—Partial Cerebritis—Lesions of the Muscular and Sensorial Functions—Comparison with those of Apoplexy—Preservation of Intellect in Cerebral Disease—Production of General Symptoms by Local Lesion.

GENTLEMEN,—To-day we commence the consideration of the diseases of the nervous system, and here let me remark, that even on the very threshold we have to encounter several difficulties, some depending upon the great obscurity of the symptoms, some upon the want

of correspondence between the symptoms and known organic changes, and some upon the necessarily imperfect nature of our classification of nervous affections. Many persons are in the habit of taking a limited view of the nervous system. They suppose, that, when we speak of its diseases, we merely allude to affections of the brain and spinal cord, but the truth is that the nervous system, so far as regards organisation, is universal; and there is evidence to show that, even in parts and tissues which present no appearance of nerves, or nervous communication, there resides a nervous power, either inherent in their organisation, or derived from external sources, and by the latter mode, of *nervous irradiation from surrounding tissues*, has the sensibility of serous membranes been supposed capable of explanation. But there can be little doubt, that even these tissues present nervous expansions, though of an infinite delicacy. They are, we know, supplied with white vessels, and doubtless have nerves corresponding to their vessels in size and function, — nerves, insensible to us in health, but, when inflammation elevates the organ in the scale, capable of transmitting the most exquisite pain to the centre of perception. It seems, also, to be highly probable, that nervous disease may commence not only in an affection of the brain or spinal marrow, but also in a similar condition of any part of the system. Again, if we admit the nervous system to be the governing and directing portion of the whole body, it is likely that some modification of that government *precedes* the alterations which take place in the circulatory and nutritive functions of other parts. Thus, in all diseases it may be laid down as a general rule, that there is an affection of the nervous system, either local or general; or, in other words, that there is no disease which we could name, which does not present signs of an affection of the nervous system, either *quoad* the suffering organ itself, or of an affection more general and diffused. If we take, for instance, a case of gastritis, or hepatitis, we find a lesion of function in the nerves of the respective organs, which, in certain cases, seems local, but if the inflammation be intense and the fever high we have superadded to this a sympathetic affection of the brain, or spinal cord. The same thing applies to all forms of local disease, for in all there is an affection of the nerves, either confined to the suffering organ, or extending to the whole system.

In reviewing the phenomena of nervous diseases we find them presenting several varieties depending upon certain circumstances. In the first place, they vary according to the seat of the disease. We find that the signs and symptoms of affections of the cerebro-spinal system differ very considerably from those which characterise diseases of the sympathetic nerves. Again, if we take any part of the nervous system and examine its dis-

eases, we find that here also there is a source of variation connected with the peculiar part affected. Thus, if we take the cerebro-spinal system we find that disease of one part of it differs most essentially in symptoms from disease of another; we may have enormous and fatal disease of the spine without the slightest injury of the intellectual powers, but we seldom have disease of the brain, particularly of the surface, without a more or less appreciable lesion of the phenomena of the mind. To follow up this point, suppose we take the diseases of the brain itself as compared with each other; we find that their symptoms vary according to the locality, so that whether we look to physiology or pathology we must consider the brain as consisting of several distinct parts, and not as an inseparable whole. It is admitted by many writers of high authority, that there is a difference between the symptoms of disease affecting the periphery, and disease affecting the central parts of the brain; and there is reason to believe, that we may be able in many cases to diagnosticate affections not only of the centre and periphery of the cerebrum, but even of other parts of the organ.

The same variety occurs with respect to the effects of diseases of the nervous centres. In some instances we have, as the result of disease of the brain, a loss of muscular power or of sensation, in different parts of the body, sometimes affecting the face, sometimes one side, or even both; and these paralyses may be single or variously combined. It appears, then, that the component parts of the nervous system, by being to a certain extent separate and distinct, furnish a very extensive source of variety in the phenomena of nervous affections.

Lastly, we have the varieties which depend upon the nature of the lesion. We generally observe an obvious difference between cases of nervous disease, accompanied by some *known change* in the injured part, and cases in which no such change can be demonstrated. Thus, for instance, we know the symptoms of apoplexy, and that, in the majority of cases, it is a disease connected with some perceptible change in the circulation of the brain, as excessive distension of its vessels, or an effusion of blood on its surface, or into its substance. We also have some idea of the nature of inflammation of the brain, we know that its substance becomes at first red, then begins to soften, and finally is converted into a pulpy mass. Now, there are a number of symptoms, which are so often and so constantly connected with peculiar organic changes, that the symptoms being known we can make a tolerably correct guess at the nature of the alteration, or vice versa.

On the other hand, however, we have a large and important catalogue of nervous affections, in which the symptoms give but very unsatisfactory information as to the real

nature of the disease, and to the elucidation of which the painful and long-continued investigations of the pathological anatomist have hitherto been directed in vain. Of the actual nature of a numerous, complex, and interesting class of diseases—the *neuroses*, we know nothing. All we can say of them is, that they are examples of lesions of function in various parts of the nervous system, presenting no trace of structural alteration *appreciable by our senses*. It is a startling fact, and one which must be a source of gloomy reflection to the pathologist, that many of the diseases of the nervous system, which present the most violent symptoms, are those in which there is the least perceptible organic alteration. Every man who has seen a case of hydrophobia, or tetanus, or mania, or epilepsy, has witnessed a train of extraordinary and horrible symptoms, infinitely worse than those which are seen to accompany even great organic alterations of the brain.

Here then is a singular fact,—that there is a part of the system presenting a series of diseases under this extraordinary law, that the most violent and frequently fatal symptoms are accompanied by the least perceptible organic alteration. Now what is the nature of these neuroses? To give you a familiar illustration, let us take a case of tetanus or hydrophobia as an example. Here we have a train of symptoms exhibiting the most frightful irritation of the nervous system; and yet, when we come after death to examine with eager curiosity the cause of all these appalling phenomena, what do we find?—Nothing. There is no unequivocal, no constant, no prominent alteration of any part of the nervous system, to throw light upon the obscurity of our opinions, and enable us to fix the nature or locality of the disease. We lay aside the knife in despair, and bitter indeed is the consciousness of our ignorance.

Two opinions have been entertained by pathologists with respect to those singular affections:—one, that they are examples of some peculiar modification of the nervous influence, *independent of any organic change*. In other words, the pathologists who entertain this opinion hold, that the principle of life may be altered in its phenomena, and admit of modifications, independent of any molecular change. The supporters of this doctrine reason thus:—In the phenomena of neuroses we have a train of extraordinary and violent symptoms unconnected with organic change. Now, it is quite unphilosophical to say that there is organic change when we cannot see or demonstrate it; and, on the other hand, it is not absurd to suppose that we may have lesions or peculiar modifications of the nervous principle without any organic alteration. The other opinion is, that in the neuroses there is some organic change, the nature of which cannot be ascertained, in consequence of our limited powers of detecting

elementary changes. In whatever light we view this question, it appears to be surrounded with difficulties. No one can deny that neuroses are very different from organic diseases of parts. If we compare them with that class which is most familiar to us,—the inflammatory affections, we find a remarkable difference. In the first place, the neuroses may be brought on by causes not reckoned among those commonly capable of exciting inflammation. In the next place, their invasion is sudden, and their progress rapid; they arrive at their acme in a very short period of time, and subside rapidly. These are characters which do not belong to the ordinary forms of organic disease. Again, we often observe the utmost intensity of nervous pain without the co-existence of swelling, redness, or heat of the part affected. We find, too, that they are not to be subdued by the antiphlogistic plan: on the contrary, several of them are either relieved or cured by an exactly opposite line of practice; and many cases which would appear to demand the lancet are known by long experience to be most benefited by stimulants. Lastly, the most accurate and well-conducted investigations of pathological anatomy have failed in demonstrating the slightest organic change in these cases,—at least, where changes are found, these are *neither constant, competent, nor commensurate with symptoms*; so that whether we compare the information we derive from symptoms, or the result of pathological anatomy, we find a great difference between neuroses and organic diseases. It may be said, that though they are not inflammatory affections, they have some resemblance to them. This, however, is only a gratuitous supposition; for even in the very worst cases they present nothing analogous to the results of inflammation, and the brain and spinal cord are as free from perceptible organic change in the majority of cases of fatal tetanus and hydrophobia, as they would be in nervous affections of a slight and transient character.

You must have been already convinced, gentlemen, that it is difficult to form any clear or definite notion of the nature of neuroses;—indeed the only thing we can say of them, is what they are not. When we reflect on nervous phenomena, and consider how occult, how mysterious the properties of those organs which give rise to them are, we are struck with astonishment at the discrepancy between cause and effect. No medical man has ever witnessed a case of confirmed tetanus or hydrophobia, without being oppressed with a conviction of the imperfect and limited state of our knowledge of nervous disease.

It may be very possible, that in these neuroses the change, though so slight as to escape our means of detection, does absolutely occur, and yet such is the nature of nervous phenomena, that we must admit that great and extraordinary effects are produced by very slight causes. Do we see anything li-

nature! any remarkable alterations in properties depending upon apparently slight causes? We do; we see extraordinary changes taking place in the characters of various inorganic substances (to which I need not particularly allude), and there is no reason why the same thing should not occur in organic structures. On considering the doctrine of isomerism, I should be inclined to think that it throws some light on this obscure subject. In chemistry, it is a well-known though singular law, that the properties of two bodies may be essentially different at the same time that their respective component elements are, as far as our knowledge goes, identically the same; and the change, whatever it may be, appears to result, not from the abstraction or removal of any of the component atoms, but from their peculiar juxta-position. Now, it being admitted, in chemistry, that many bodies having the same constitution possess totally different properties; and this difference being explained by the different position of their elements, it does not seem strange if the same thing should take place in the phenomena of organised beings; and if this be the case, we have a key towards elucidating the nature of these neuroses, and can conceive how an analogous change, a difference in the arrangement of the molecules of the component parts of the nerves, or their centres, may produce new modifications of their properties, without making any distinct change in their nature, or adding or abstracting a single organic molecule. I am much inclined to adopt the opinion of those who think, that in the neuroses a peculiar organic change actually takes place, though we cannot demonstrate its existence, because, to reason on the phenomena of animal life independently of organisation is to plunge blindly into hypothesis, and retrace the errors of an antiquated and exploded school.

In treating of the diseases of the nervous system, I regret that time will not permit me to enter into the subject as fully as I could wish; all that I hope to be able to accomplish is, to give a sketch of some of the more prominent affections. The arrangement I purpose to adopt is the following:—1st, I shall treat of local inflammations of the brain; 2nd, of general inflammations of that organ; 3rd, of mere sanguineous congestion or hyperæmia of the brain; 4th, of apoplexy; and 5th, of the various forms of paralysis.

In taking up the subject of cerebral inflammation, I beg leave to observe, *in limine*, that the brain may be attacked by general or local inflammation; and further, that it may, as stated in books, be inflamed in its membranes or in its substance, or in both together. A great deal has been written to show that we can distinguish during life between inflammation of the substance and of the membranes of the brain. On this point, I believe, we may come to this conclusion,—that inflammation of the membranes of the brain, or arachnitis, may be distinguished from some cases of local in-

flammation of the cerebral substance, but that it cannot, in the present state of our knowledge, be distinguished from *general* inflammation of the brain. We can, in most instances, make a distinction between local disease of the brain and arachnitis; but when the whole substance of that organ is affected, our means of diagnosis fail. This, however, is not so much to be regretted, as the distinction is of very little consequence so far as treatment is concerned. Here we arrive at the knowledge of a principle highly consolatory in the practice of medicine, namely, that in many acute cases where the diagnosis between two diseases of neighbouring parts is difficult or impossible, it is also, so far as regards immediate treatment, unnecessary.

If we inquire what are the symptoms of membranous inflammation of the brain, as laid down in books, we shall find them to be the following:—pain, delirium, convulsions, alteration of sensibility, and coma. These are the symptoms which are generally given as characteristic of arachnitis; and it is quite true that they are observed in many cases of the kind. But the person must be dull indeed who thinks that such symptoms imply nothing more than an inflammatory affection of the membranes of the brain. Take for instance one of the most prominent symptoms—delirium; what does this imply? that the portion of the brain which discharges the functions of intelligence or mind has been injured, and is rendered incapable of performing its office. No one will venture to assert that the membranes of the brain are the organs of thought, and that the delirium proceeds from *their* morbid condition; such a notion as this could not be entertained for a moment. What then are we to suppose? One of these two things—either that there must be inflammation of the substance as well as of the membranes, or that the substance of the brain must be affected in a neurotic manner without any actual inflammation. As far as delirium is concerned, it appears to me to be quite impossible to distinguish between inflammation of the brain generally, and of its membranes. The same rule applies to the other symptoms, convulsions, alteration of sensibility, and coma. I repeat, that all we can say on this subject is, that in such cases there is either inflammation of the substance as well as the membranes of the brain, or that, with the membranous inflammation, there is a neurotic condition of the substance of the brain. Yet who, in such cases, can affirm with certainty that the symptoms of derangement of the substance of the brain are merely neurotic, when inflammation is admitted to exist within the cranium, and when we know that the two inflammations commonly co-exist?

The fact of delirium occurring so frequently in inflammation of the membranes of the brain, is of considerable importance, as showing, not that membranes of the brain have anything to do with intelligence, but as supporting the

opinions of those who believe the periphery of the brain to be the seat of the intellectual faculties, and here is a fact which, as far as it goes, is in favour of the doctrines of phrenology. If we compare those cases of cerebral disease in which there is delirium, with those in which it does not occur, we shall find that it is most common in cases where disease attacks the periphery of the brain, as in arachnitis. The cases in which we observe great lesions of the brain without delirium, are generally cases of deep-seated inflammation of a local nature, or inflammation of those portions of the brain which the phrenologists consider not to be subservient to the production of mental phenomena. This fact, also, would seem to confirm the truth of the opinion of the difference in function between the medullary and cortical parts of the brain. It is supposed that the cortical part of the brain is the organ of intelligence, while the medullary portion performs a different function. It is, however, a curious fact that in delirium the inflammation is generally confined to the surface of the brain, and that in cases of deep seated inflammation, the most important symptoms are those which are derived from the sympathetic affections of the muscular system.

Partial encephalitis may be either primary or secondary. An example of the latter is that inflammation of the substance of the brain which supervenes on apoplectic effusion, tumours, or cancer. What we generally observe in a case of this kind, is more an alteration in the functions of the muscular system, and less of the intellect. This alteration consists at first in an apparent increase of innervation in certain muscles of the body, and we generally find that one of the earliest symptoms of local encephalitis is the occurrence of pain in some of the muscles of the extremities. This is a curious fact, but one which is well established. In partial encephalitis there is often but little, or even no pain in the head, and the only warning we have of the approach of cerebral disease is the occurrence of pain in the extremities, followed by rigidity. Here are the two most prominent symptoms of the disease, pain in the muscles of the extremities, and then rigidity. Further, we have alternate spasms and relaxations of the muscles, in which, however, the power of the flexor muscles ultimately prevails, so that, if the disease be in the fore-arm, it may become permanently flexed on the arm, and the contraction of the fingers is sometimes so great as to drive the nails into the flesh. If it affects the leg, the heel may be pressed against the buttock sometimes so forcibly as to form a sore. As the case proceeds, the limb becomes more fixed in its new position, and every attempt to extend it causes pain. During the prevalence of these symptoms, it frequently happens that the patient does not feel pain in the head, or any diminution of intellectual power. The absence of pain in the part affected may be accounted for

by recollecting that it is a general law that all inflammatory affections of deep-seated parts are, to a certain extent, of a comparatively painless character, and we may account for the non-existence of any lesion of the mind, by remembering that the disease is partial, and confined to a portion of the brain which appears to have little or no connection with the intellectual functions. In cases of this kind, when the muscles of the face are affected, the phenomena are interesting, from their being (*in the first stage*) the reverse of those of apoplexy. The face is drawn *from* the affected side, and the tongue pushed, by the opposite half of the genio-hyo-glossus muscle, *to* the affected side. This is the spastic stage, when complete disorganisation has not yet occurred. But when this happens, then the phenomena of the face are like those of apoplexy, because the opposite muscles, which were in a spasmodic, are now in a paralysed state, so that the face is drawn *to* the affected side, and the tongue pushed *from* it, by the healthy action of muscles which are deprived of their antagonists.

I mentioned before, that delirium may not occur during the course of a partial encephalitis; and I gave as a reason for this the circumstance of the disease being of small extent, and confined to parts of the brain which do not discharge any of the functions of mind. Another explanation has been given, drawn from the consideration of the double nature of the brain. It is thought that where disease exists in one part of the brain, sanity may be still preserved in consequence of the healthy condition of the corresponding part, but where disease attacks both hemispheres together, as in a case of arachnitis, then there is a distinct lesion of the mental faculties.

The next stage of partial encephalitis is that in which the diseased portion of the brain breaks down, softens, and is converted into purulent matter. This stage is marked by a new train of symptoms. The first stage is characterised by pain occurring in the muscles of the face, or of the extremities of either side, and followed by great rigidity. The second stage is of a different character; the rigidity and spasm of the muscles diminish, and are succeeded by a paralytic and flaccid state of these organs. Voluntary motion on the affected side now becomes impossible, the organ on which it depends being destroyed. Now, let us, for sake of arrangement, call the first, or spastic condition, the convulsive paralysis, and the second, the paralysis with resolution. In the first, or convulsive stage, the brain is affected in the first degree; it is labouring under irritation or actual inflammation, and the disease still holds out a tolerably fair prospect of relief or cure. But in the second stage a cure is impossible, and hence it is a matter of the greatest importance to commence our operations at an early period, and, by having recourse to prompt and active

treatment, give the patient every chance for a cure.

In the partial inflammation of the substance of the brain, sensation is variously altered. In some cases motion is lost, while sensation remains intact; in others, sensation is partially or wholly abolished. In many instances the intellectual powers remain in all their integrity, or but little impaired, even after the occurrence of symptoms which mark the softening down of the substance of the brain, and its conversion into purulent matter. In a few there is, during the first stage of the disease, a slight alteration in the state of the intellect, marked by a certain degree of excitement or exaltation of the mental faculties, and this, on the supervention of the second stage, is exchanged for a state of depression. In fact, the morbid phenomena of the mind and of the muscular system, where they co-exist, appear to be regulated by the same laws. Where the disease is extensive, you can easily observe the injury of the mental faculties which accompanies the second stage; the patient answers slowly when questioned; his memory is weak, and his countenance has a stupid expression. But cases, even of extensive local suppuration, have been described by various authors, in which there was no lesion of the intellectual functions observed. These, however, generally admit of an explanation. Thus, in the cases recorded by Lallemand, the abscesses were situated in the cerebellum, pons Varolii, and other parts which are not supposed to have any connexion with the phenomena of mind. There are several well authenticated cases of extensive disease, not only of these parts, but even of the substance of the hemispheres, occurring without any appreciable lesion of the intellect. Thus, Mr. O'Halloran gives the case of a man, who, after an injury which destroyed a large portion of the frontal bone, had extensive suppuration of the brain, and lost an enormous quantity of the substance of one of the hemispheres, and yet preserved his intellect entire up to the moment of his dissolution. There is some difficulty in explaining this. It is an opinion entertained by some physiologists, that, when one hemisphere is diseased, its functions are discharged by the other, and that the brain being a double organ, disease of one side does not impair the functions of the other. But in answer to this, it may be urged, that there are many cases on record, in which disease of a *single hemisphere* has produced great alterations of intellect. The supporters of the former opinion attempt to explain such cases in this way. They state, that in the majority of such cases there was, besides the local encephalitis, inflammation of the arachnoid membrane, and that the lesion of intellect was not so much the effect of local disease of the brain as the result of its complication with an arachnitis engaging the whole periphery of the organ. In the

worst place, they explain the fact of a *general* affection of the brain arising from *local* disease, as depending in most cases on the pressure which the tumefied state of the diseased portion necessarily makes on the sound hemisphere; and they state that this pressure must be very considerable, as the brain, being confined within a bony cavity, has no power of expanding itself. Now, it is a most interesting fact, in support of this view, that in a great number of the cases of loss of brain with preservation of intellect *all through the case*, an extensive opening existed in the bones of the skull, so as to permit of expansion in the diseased hemisphere, and prevent the pressure being exercised on the opposite one. This point appears to be borne out by the result of Mr. O'Halloran's cases, and by many other examples. Lastly, in every acute case of local inflammation of the brain, two causes having a tendency to produce symptoms exist. One of these is the local disease which gives rise to those phenomena of motion and sensation which we observe on the opposite side of the body; the other is the determination of blood to *the whole brain*, the result of the irritation of that disease.—“*Ubi stimulus ibi humorum affluxus.*”

CLINICAL LECTURES ON SURGERY,

DELIVERED AT

THE HOTEL DIEU, PARIS,

BY BARON DUPUYTREN,

PRINCIPAL SURGEON OF THAT HOSPITAL.

Corrected by himself.

Cystotomy—Different Regions in which it is performed—Symptoms of Stone in the Bladder—Difficulty of Detection—Different Methods of using the Catheter—Scrofulous Tubercles in the Bladder cause of all Symptoms of Stone—Uncertainty of Catheterism—Importance of a minute anatomical knowledge of the Parts concerned in the Operation for Cystotomy—Anatomical Demonstration of the Parts connected with the Hypogastric Operation—A minute description of the Perineal Region—Attachment of the Fascia—Importance of the Diameters of the different Triangles: their exact extent—Proportion of Deaths to Cures—Table of Cases—Preparations for the Operation.

GENTLEMEN,—The operation for stone has, without doubt, occupied the attention of surgeons more than any other. Important discoveries, various manœuvres, and numerous modifications have been made, and such, in a few words, is the history of this important operation. It is not my intention to enter into a full history of all that is known on this subject; dictionaries, and the works *ex professo*, will furnish you with the different pro-

ceedings that have been employed. I will draw your attention only to the most successful means we have arrived at in cystotomy, and mention to you the most striking cases that have occurred, and present themselves daily in this hospital. The operation is performed, at the present day, in four different regions, namely, above the pubes or hypogastric; below the pubes, or the sub-pubic or perineal; the recto-vesical; and by the destruction of the stone in the bladder without incision. All these have been tried, and their advantages and disadvantages are known to us; but, before pointing them out to you, it will be necessary to tell you the symptoms by which we recognise the existence of stone in the bladder, the anatomical disposition of the parts, and the different precautions necessary before undertaking this operation.

The principal symptoms which reveal to us the existence of a calculus are, a constant sensation of weight; obtuse, vague, and even extreme pains about the region of the bladder, and in the fundament; difficulty, and even impossibility, to ride on horseback, or in a jolting carriage, without which the pains are not much increased; the frequent discharge of bloody urine, or even pure blood caused by the irritated state of the bladder; the flow of urine irregularly interrupted; pain at the glans penis, or at the navicular cavity, and which obliges the patient to make incessant pressure on these parts, and to lengthen, as it were, the urethra and prepuce; finally, all the local and sympathetic phenomena of chronic cystitis. None of the above named symptoms, however, arising separately, or even if they all exist, can for a certainty indicate the existence of a stone in this organ. Chronic inflammations, especially those which attack the inferior part or neck of the bladder, and which are complicated with the presence of fungous growths, or owing to a varicose development of the vesical veins, are able to produce such symptoms, as even to deceive the most experienced surgeon.

An examination of the bladder is, then, indispensable; and the ideas furnished by the catheter, in these cases, are as valuable as various. The instrument does not always reach the situation of the foreign body: it frequently fails from the smallness of the stone, and sometimes in consequence of the stone being retained in a part of the bladder not accessible to the instrument. In the greater number of cases it is necessary to pass the point of the instrument to the most sloping part of the bladder, and if there, the stone cannot be found, to carry it to the pubic region, to the summit, and to the sides of this organ. These manoeuvres must be repeated both when the bladder is distended with urine, and when in a state of vacuity.

In general, the external opening of the instrument is closed, so as to prevent the discharge of urine, and thus keep the bladder in a state of distension; but, towards the latter

part of the examination, it is frequently useful to permit, on the contrary, this organ to evacuate itself, the instrument being kept still, and the flow of urine will sometimes cause the calculus to strike against the extremity of the instrument.

In obscure cases, it is the duty of every practitioner to make his examinations repeatedly, and at different times, with solid and hollow instruments of different dimensions and curvatures, and never to perform the operation unless the calculus can be detected.

CASE 1st.—An infant, eighteen months old, was brought into this hospital about the first week in January, 1827. His mother assured me that at intervals he suffered from acute pains in the region of the bladder, accompanied with great difficulty to void his urine. I passed the sound, but was unable to detect the existence of a calculus. Some time afterwards he was brought again, and many times at different intervals I made an examination; sometimes I believed there existed a stone, at others I was unable to detect it. He was brought to me a third time, his mother begging of me to deliver her child from such incessant torment; the pains, she said, were so acute, that in the middle of the paroxysm the child was taken with severe convulsions. I admitted him with his mother into the hospital, and a few days afterwards had him brought into the operating theatre. On this last admission I thought I could feel the calculus, and I said at the time, should this be actually the case, it is the first that I have met with of stone in the bladder in a child so young; and for more than six months the symptoms had made their appearance. The stone appeared to exist at the inferior fundus of the bladder, and towards the right side. Many of you, doubtless, recollect the case of a child who was admitted about a year since into one of these wards: this infant, who was only two years of age, experienced for some time acute pains similar to the one I am speaking of; he was sounded, and a calculus was thought to have been detected. I examined him also, and was of the same opinion. I repeated my examinations at different periods; sometimes I was able to detect the existence of a stone, at others I could not. Having determined to perform the operation, the child was brought into the operating theatre; I there sounded him again, and was fully convinced of the existence of a calculus. The operation was immediately performed, and, in spite of the most attentive efforts, I was unable to find the stone. The wound was kept open; I continued my researches; sometimes the sound appeared to grate against a foreign body, and at others not to meet with it. The child still suffered at intervals from the excruciating pains, and I believed that the stone, which I so frequently encountered, was lodged in the right ureter, and disappeared at the suffering moments, believing the contractions of the ureter to be the cause

of this deception. The child emaciated, and I had no hopes of his recovery, when suddenly the pains ceased, and did not reappear, and the child soon regained its health and spirits. Sometime after this the child again became ill, was taken to the Hôpital des Enfants, and died. On examining the body, at the lower part of the fundus of the bladder, to the right side, and near the orifice of the ureter, were discovered some scrofulous tubercles in a state of suppuration, the lungs also were affected with this disease. Is it not probable that the tubercles in the bladder gave the shock to the instrument, which led me to believe the existence of a calculus?

The case under consideration presents symptoms very similar to the one I have just quoted. It appears also that the stone is lodged in the right side of the bladder, and sometimes it is not distinguishable. I examined the child with the greatest care, and employed in the operation the buttoned stylet. The catheter, owing to its great curvature, will prevent you, in many instances, from examining with facility the different regions of the bladder, and a hollow sound has the inconvenience of receiving urine in its cavity, and air is introduced at the same time; the shock of these liquids, their density being so different, resembles frequently that communicated to the instrument by the calculus. The stylet, from its easy curvature at pleasure, and from its not being excavated, prevents all these inconveniences.

In examining the child, first with a stylet, then with a catheter, and afterwards with a hollow sound, without detecting the existence of a foreign body, I deferred the operation.

Five days afterwards I made a second examination, moved the instrument in every direction without striking against a foreign body, but at length carrying it to the lower fundus of the bladder, and giving it a direction from above downwards, it grated against a hard substance, which appeared, as it were, to retain it. This kind of movement was repeated several times, both by myself and my colleague, M. Sanson, and the same sensation was at every attempt reproduced. I suspected that the sound conveyed to us, by thus directing the instrument, resulted from its meeting a fleshy column in the bladder, for upon moving it from before backwards, and from right to left in this situation, no grating was produced; I then made the point of the instrument, by moving it in the same direction as at first, strike against this fleshy body, and the same impression was again conveyed to me. My opinion coinciding with that of my colleagues as to the nature of the disease, the operation was condemned, and the child sent back to his mother.

This case was not only interesting, as regards the age, but also points out the uncertainty of catheterism in all cases; and the confused ideas, conveyed to it by different vesicle dis-

eases, also shows the importance of using every manœuvre for the detection of a stone. The examination per rectum, the patient lying on his back, and the surgeon with his right hand pressing on the hypogastric region, furnishes in certain cases useful indications relative to the volume, weight, and situation of the calculus, as well as the healthy or morbid condition of the prostate, and, to a certain extent, the suppleness or hardness of the walls of the bladder.

After detecting the existence of a foreign body in the bladder, it must be extracted either through the medium of the natural passage, by seizing it with a pair of forceps, by reducing it to fragments, or by making a passage through the soft parts into the cavity of the bladder, and thus extract it through the opening.

The attempts of breaking the stone, I imagine to have been ineffectual; and it is not at present adopted for the reasons I will explain to you hereafter. Cystotomy is the most certain, and the operation most frequently employed: but two difficulties here present themselves; either the division in the walls of the bladder is not sufficiently extensive, or else is too long. In the first, the parts are torn, bruised, and inflammation is the consequence; in the second, from the length of the incision there is danger of urinary infiltration.

The hæmorrhage that frequently results is not less important, and must be prevented; as to the concomitant affections, it is difficult to foresee them. It must be recollected, that the traumatic fever increases all morbid dispositions, causes symptoms to appear, which might otherwise be concealed in the viscera. Every attention must be paid to the action of the different functions, and a perfect health of the different organs is requisite, before the operation is undertaken.

It will be needless for me to impress upon you the necessity of a thorough knowledge of the structure, dimensions, and relative position of the parts on which the surgeon is required to operate, it must be evident to all of you. It is not my intention to give you a minute anatomical description of the parts, but shall limit myself to those points which are most practical. There are three regions in which the operation is performed, as I have before named to you; one above the pubes, called the hypogastric, the other below, called the perineal, and the third, called the recto-vesical; the latter in women is called the vagino-vesical. I will first call your attention to the hypogastric, or the one performed above the pubes.

This region is limited above by an horizontal line drawn from one anterior superior spinous process of the ilium to the other, and below, by a semicircular line, the circumference of which is opposite to the attachment of the fallopian ligaments to the pubes. This region

is covered by skin, beneath which is cellular tissue, of greater or less density, a few ramifications of the tegumentary and external genital vessels terminate about the median line.

Beneath this cellular tissue, we come to a dense fascia, which covers the external oblique muscle, and underneath which is the aponeurosis belonging to this muscle, these tendinous fibres intermixing with the fibres of the opposite side become more dense, unite, and form the linea alba; this ligamentous line, which assists in supporting the anterior abdominal parietes, is fixed to the sternum above, and to the symphysis pubis below. Behind the aponeurotic expansion of the external oblique, and to the sides of this ligamentous line are found the recti muscles, the internal fibres of which are separated from one another by this line, and run parallel with it, and inferiorly are situated between it and the pyramidales muscles, which are not found in all subjects. The external borders of the recti muscles are directed obliquely from above downwards, and from without inwards, and are attached to the spine of the pubis. Externally to these muscles we observe the internal oblique, and transversalis, their aponeurotic expansions pass before this muscle inferiorly, and unite with the linea alba.

After having raised the abdominal muscles, we arrive at a dense cellular expansion, to which the name of *internal fascia* has been given (*fascia transversalis*). Next we come to the peritoneum, which appears descending from the umbilical region. Arriving near the pubis, it is reflected on the superior region of the bladder, and from thence to the vagina, uterus, and rectum.

The bladder, when in a state of vacuity, is situated behind, and nearly concealed by, the symphysis pubis, but when distended lies in the hypogastric region, extends to, and sometimes even above the umbilicus, applied against the recti muscles, and fascia internalis. From its globular shape, it is placed more in contact with the pubis, and in the inferior abdominal region against the median line, than on the sides. When the bladder is empty, by passing a catheter, you may easily distinguish its summit above the symphysis pubis. After dividing the inferior part of the white line, it is necessary to push upwards the fold of peritoneum, and you immediately expose the anterior part of the body of the bladder.

Perineal, or sub-pubic region.—This region is triangular, the apex corresponding to the junction of the symphysis pubis anteriorly, bounded laterally by the rami of the ischium and pubes, and the base posteriorly by the rectum.

The skin of the perinæum is thin, elastic, and furnished with hairs; beneath this is a layer of cellular tissue, covering a fibro-cellular expansion, enveloping the perineal muscles, the bulb, and spongy portion of the

urethra. This is the superficial fascia of the perinæum, arising from the sciatic tuberosities, from the inferior surface of the middle aponeurosis in front of the rectum (triangular ligament), laterally it has a strong attachment to the rami of the ischium and pubis, and anteriorly is connected with the dartos. This aponeurosis separates the rectum from the genital and urinary organs.

On removing this, we observe posteriorly, and in the median line, the external sphincter muscle, the anterior extremity of which divides into two fasciculi, a superficial and deep, the former being connected with the sub-cutaneous aponeurosis, and the other with the bulbo-cavernous and transverse muscles of the perinæum.

Along the median line, and anterior to the sphincter ani muscle, eight or ten lines from the anus, we find the bulbous portion of the urethra, covered by the bulbo-cavernous muscles, forming for it a moveable and very contractable investment. After having covered the bulbous portion of the urethra, these muscles diverge from one another anteriorly, and unite with the corresponding corpus cavernosum penis, their action being for to raise, and compress the bulb.

The transverse muscles of the perinæum are situated a little deeper, at the union of the bulbo-cavernous with the sphincter ani. These constitute two fleshy fasciculi, passing obliquely from without inwards, and from behind forwards, extending from the tuberosities of the ischium to the raphe of the perinæum, intermingle with each other, and with the preceding muscles.

On the sides of the perineal region, and applied on the ascending branches of the ischium and pubis, are the roots of the corpora cavernosa, enveloped at their origin by the expansion of the erector-penis muscles, in a similar way that the bulb is covered by the bulbo-cavernous.

From the internal edges of the ascending branches of the ischium, and descending branches of the pubis, an aponeurotic lamina is detached, arising from without backwards from the external face of the superior aponeurosis, at the junction of the superior border with the levator ani muscle; in front this aponeurotic lamina has received the names of middle perineal fascia, fascia of the levator ani muscle, and the perineal ligament of *Carcassonne*. It is continuous with the inferior pubic ligament, and directs itself from thence to the sides of the bulb of the urethra, which it fixes in the median line; towards the circumference of the margin of the anus, it extends upwards, between the digestive, urinary, and genital organs, so as to form a second fibrous lamina, perforated only, as that of the superior aponeurosis, for the passage of the middle organs. Below the symphysis pubis, we always find a hole, somewhat inverted, for the passage of the dorsal arteries and veins of

the corpora cavernosa. The middle aponeurosis is very strong anteriorly, and thin posteriorly; its superior face corresponds to the levator ani muscle; the inferior and external gives origin from without to a fibrous lamina, which descends perpendicularly on the sides of the pelvis, and terminates on the internal border of the great, or posterior sacro-sciatic ligament, and retains in its duplicature the trunk of the pudic artery on the inner surface, and inferior part of the side of the ischium.

On the sides of the perinæum between the urethra, which is covered by its muscles, and the corpus cavernosum, exists a triangular space containing much cellular tissue, which extends from the integuments to the prostate gland, and bladder. This kind of canal is prolonged posteriorly on the sides of the rectum, limited in this direction only by the levator ani muscle, and the superior perinæal aponeurosis; anteriorly we find it limited by the junction of the corpus cavernosum. About eight or ten lines in front of the rectum we find the transverse muscles of the perinæum, accompanied with an artery of the same name, thus interrupting its regularity. On the external side we observe the superficial perinæal artery; posteriorly we come in contact with the inferior and middle hæmorrhoidal arteries, also a considerable venous plexus.

Above the parts I have just described we find the prostate gland placed on the anterior part of the rectum. Around these two organs are obliquely descending the converging fibres of the levator ani muscles, which embrace, fix, and sustain them in their position, thus forming in this region a contractile plane, which strongly opposes the combined actions of the diaphragm and abdominal parietes. This fleshy bed is still further strengthened superiorly by a prolongation of the pelvic fascia, which, from all the internal parts of the pelvis, descends on the levator ani, and is applied to the circumference of the prostate, envelops the rectum, and assists in closing the inferior pelvic cavity. This is called the superior aponeurosis of the perinæum, fascia pelvica, also the recto-vesical fascia; it represents a concave plate, and may be said to be perforated for the passage of the rectum, and the genital and urinary organs.

The disposition of the parts that I have described merit the whole of your attention, and it shows you the difference of gravity in urinal infiltrations. Thus, as the crevices of the spongy region, and of the bulb of the urethra, which perforate the superficial aponeurosis, cause only subcutaneous effusion, because the spongy portion of the urethra, its bulb, the sphincter ani, the ischio-cavernous muscles, and the corpora cavernosa penis are placed between the middle and superior aponeurosis. The perforations of the membranous region, those of the superior portion of the rectum and external sphincter, frequently in fact give origin to deeper abscesses, which extend from the

sides of the perinæum to the margin of the anus, without communicating with the cavity of the pelvis; whilst ruptures of the bladder, above the edges of the prostate, and incisions, which pass the limits of this glandiform structure, permit urinous, or stercoraceous, effusions to glide under the peritonæum, and to extend in the cellular tissue of the pelvis, which accident frequently proves fatal. These two different results are owing to the different partitions of the fascia; in the first, the membranous part of the urethra, the prostate, and the corresponding region of the rectum, and levator ani muscles are situated between the middle and deep fascia; and in the second, above the superior fascia exists only cellular tissue, lying beneath the peritonæum, and the folds of this latter membrane around the bladder and rectum.

In continuing the examination of these parts we find in the median line, between the most inferior part of the rectum and the bulb of the urethra, a triangular space, to which I wish particularly to direct your attention; its apex corresponds to the point of the prostate, exactly at the spot where this body touches the rectum, and consequently about nine lines above the integuments, its base rests on the integuments, superficial fascia, and external sphincter muscle, and is from eight to ten lines in extent from before backwards; its anterior border is convex, and corresponds to the membranous portion of the urethra, which directs itself obliquely from above downwards, and from behind forwards; its posterior border is equally convex and prominent forwards, and corresponds to the last part of the rectum. In this transverse sense, the triangle extends from one tuberosity of the ischium to the other, and is about two inches and a few lines in length. The decussation of the muscular fibres with the fascia, of which I have before spoken, occupies its middle part, and its sides are traversed by the transversalis perinæic muscles. It is through this space that we must cut in the lateral operation of lithotomy.

The utility of a perfect knowledge in an operation of this description must be evident to you all, and not only is the disposition of the parts necessary, but the exact size of each of the parts I have described is of the highest importance. The anterior, or spongy, part of the urethra is from six to eight inches in length, and the membranous portion from seven to nine lines, covered under the symphysis, and strengthened internally by fleshy and aponeurotic fibres, and this part frequently forms a serious obstruction to the passage of a catheter. The prostate, which partially surrounds it, presents on either side, in the perinæum, a convex surface, flattened behind, and is perforated above in its central point for the passage of the urethra. Its dimensions, about the middle of life, are generally thirteen lines from before backwards, and nineteen transversely.

Formerly the neck of the bladder was considered to be placed immediately against the arch of the pubis, but it is well known at the present time, that the prostate is separated from it about nine lines. This situation of the neck of the bladder causes the right portion of the urethra to be as it were stretched, and thus renders the sub-pubic curvature less prominent, and facilitates the strengthening of this portion of the canal.

In the corresponding point, at the anterior part of the prostate, the arch of the pubis is from 20 to 22 lines in length at the junction of the middle part with this body. The rami of the ischium are separated by an interval of about two inches; and, lastly, the posterior, or rectal, corresponds to the division of the tubercles, which are distant from one another about two inches and three lines.

I have measured the thickness of the perinæum by the assistance of a pelvimètre, by placing one of its branches on the neck of the bladder, and the other upon the integuments, and I have generally found it about two inches and a quarter in depth. I must add, however, that it is liable to great variations.

The posterior, or rectal, region is the last division of the parts I am describing. It is directed obliquely from above downwards, and a little from left to right, the rectum descends from the termination of the colon to the bladder, where it becomes very nearly in the median line. In this course it presents a great curvature, and is applied on the concavity of the sacrum, and embraces the lower fundus of the bladder to the point of the prostate. In this situation the rectum takes a new curve, changes its direction, passes downwards and backwards, between the fibres of the sphincter ani to the anus. That portion of rectum, extending from the meso-colon to the external sphincter, remains uncovered by peritoneum, and corresponds posteriorly and inferiorly to the anterior face of the sacrum, to the coccyx, and to the ischio-coccygean muscles, anteriorly to the inferior part of the fundus of the bladder, from which it is separated externally by the ureters, vasa deferentia, and vesiculæ seminales, and still more inferiorly by the prostate gland, which is united to it through the medium of cellular tissue. In old people this portion of the rectum is frequently found dilated, and lodges as it were the prostate, forming on its sides two lateral projections, which are easily incised in the lateral operation of lithotomy, and requires great attention. The lowest part of the rectum, extending from the point of the prostate to the anus, is enveloped by the sphincters, and directed downwards and backwards. It forms the posterior boundary of the middle triangle of the perinæum, of which I have previously spoken.

The posterior and inferior part of the bladder, which corresponds to the rectum, is traversed obliquely from behind forwards, and from without inwards, by the ureters and vasa deferentia, and may be divided into three di-

stinct regions. Two of these may be called lateral; they are convex, larger before than behind, and placed on the outer side of the ureters, vasa deferentia, and vesiculæ seminales. The third, or middle, region is also triangular, and is situated between these ducts. The base is inclined upwards and backwards, and the apex corresponds to the prostate, and is in immediate contact with the rectum.

The sides of this triangle are formed by the converging of the vasa deferentia, which approaches the prostate with the vesiculæ seminales, traverses the thickness of this gland, where the ducts of the vesiculæ seminales join those of the vasa deferentia and the common ducts, then terminate on the sides of the verumontanum.

The following are the dimensions of the parts situated between the recto-vesical fold of the peritoneum and the external surface of the perinæum:—The triangle comprised between the membranous portion of the urethra and anus, on the highest part, is from eight to ten lines in extent. The most superior and posterior part of the prostate, from its point to the middle and posterior part of its circumference between the ureters, the canals of the vasa deferentia, and vesiculæ seminales, from seven to ten lines. Lastly, between the most raised portion of the prostate and the recto-vesical fold of peritoneum, fifteen to eighteen lines. It is along this space that the incision is made in the recto-vesical operation; and its total length varies from two inches and a half to three inches and two lines.

The different conditions of the bladder and rectum alter but slightly the relative position of these parts. The only case in which the recto-vesical serous fold descends, so as to approach nearly the circumference of the prostate, is when the bladder and rectum are at the same time much contracted, and each reduced to a very small volume; and, in such case, it is difficult to avoid it in passing the limits of the glandiform body.

I have now pointed out the general disposition of the parts which are divided in operating for stone. Hereafter, I will speak more particularly of those parts which are generally chosen for the operation, and the different methods and proceedings adopted to effect it.

I have endeavoured to ascertain a correct proportion of deaths to the number of cures resulting from this operation; but the general statistical results so widely differ one from the other, that it is impossible to place an equal reliance on them all. Therefore I confine myself to the cases that have been operated on at the different hospitals, and the suburbs of this town, within the last ten years, of which I have collected 356, and the following are the results:—

SEX.	AGE.	Number of Operations.	Cures.	Deaths.	REPORT OF CASES.	
					Died.	Cured.
Masculine	Years.					
	3 to 15	97	88	9	1 out of 11	9 out of 100
	15 to 30	59	51	8	1 out of 7	13½ —
	30 to 50	45	35	10	1 between 4 and 5	23 —
	50 to 70	74	56	18	0 out of 4	24 —
	70 to 90	7	26	11	1 between 3 and 4	29½ —
Feminine	3 to 15	7	7	0	—	0 out of 100
	15 to 50	11	10	1	1 out of 3½	10 —
	50 to 70	17	15	2	1 between 8 and 9	12 —
	70 to 90	9	7	2	1 between 3 and 4	22 —
Total . .	3 to 90	356	295	61	1 out of 6	17 out of 100
Men . .	Ditto.	312	256	56	1 between 5 and 6	18 out of 100
Women .	Ditto.	44	39	5	1 out of 9	11½ out of 100

From the proportions indicated in this table, if we take the middle period of life, we shall see what the chances of death are to the chances of cure—

:: 1 : 5 or :: 1 : 6.

This proportion appears at first sight considerable; but when we consider the importance of the parts necessarily affected, the concomitance of local and other lesions, it is not surprising.

This table also shows, that before and after puberty, and then the middle age, are the most favourable periods for the operation, and after this the chances rapidly diminish.

In the first part of the lecture I told you, that there were four principal methods for extracting calculi from the bladder. Before entering upon this subject, I will say a few words on the preparations that are necessary before submitting the patient to this operation. The season in general exercises but little influence; however, it is best to avoid, if possible, those seasons of the year in which visceral inflammations and epidemics are most prevalent. If the patient suffers from nephritic pains, they must be combated by bleedings, emollient drinks, and baths. Bleeding is also useful when the patient has a full pulse; he then should be purged once or twice, and be allowed but a light nourishing diet. The evening before the operation a clyster should be administered, so as to empty the large intestines; the hair should be shaved from the perinæum and its surrounding parts.

The difference of your prognosis of course must depend upon the individual. In women and children the cures are more numerous than in adults and the aged. If the operation is performed quick, and without causing much pain, the chances of success are favourable. In nervous habits the operation is less successful than in those of an opposite condition.

Again, those individuals whose constitution has become affected from long-continued suffering, and who have, either in the bladder or in any other organ, extensive lesion, little hopes are to be expected from the operation, and it had better be deferred.

In my next lecture I shall continue with the operation above the pubis, or hypogastric.

OBSERVATIONS MADE IN THE CLINICAL OPHTHALMIC WARDS IN VIENNA, DURING THE WINTER AND SPRING OF 1832–33.

BY WILLIAM BROWN, M.D.,

One of the District Surgeons of Glasgow.

THE great eminence of Professor Beer gave a celebrity to the Ophthalmic School of Vienna, which was not speedily to decline. The combined eminence of Dr. Rosas, successor to Beer, and of Dr. Jaeger, Professor of Ophthalmology in the Josephine Military Academy of Vienna, could not fail to maintain the dynasty of professional talent in the Ophthalmic School of the Austrian capital; and, accordingly, it still continues the great focus of ophthalmological literature in Germany. Besides conducting the Clinics for the Diseases of the Eye, Professor Rosas and Jaeger give courses on the anatomy, physiology pathology, and operative surgery of that organ. The clinic of Professor Rosas is conducted in the Latin language, but his course on the eye is in the German. Professor Jaeger's clinic and instructions are entirely in the German language. Besides their public courses, both Professors

give *privatissima* on the Operations of the Eye, which, if it be preferred by the individuals who attend them, will be delivered in the French or the Italian language. Professor Jaeger gives advice in his own house at a stated hour of the day, affording an admirable opportunity of observing a great variety of interesting eye diseases. He is in the habit of inviting the attendance of the foreign graduates in medicine who frequent his clinic.

An assistant, who resides in the hospital, is attached to each clinic, whose duty it is to officiate in the absence of the Professor, and to attend to the general economy of the department. The drawing out reports of the cases which are to be treated in the clinic is no part of his duty: this is the business of the students, who, as Professor Rosas used to remark, constituted essential instruments in managing the clinic. When a patient is received, he is committed to the charge of one of the attending pupils, who all receive cases in succession. Under the superintendence of the Professor, and in the presence of his fellow-students, he examines the case, and prescribes the requisite means of cure, assigning at the same time the rationalia of the adopted measures. Every disordered appearance of the eye is detailed according to an established arrangement of parts. The diseased appearances, when such exist, of the eyelids, of the secreting and excreting lachrymal organs, of the different tunics, of the cornea, the iris, the aqueous humour, and of the other transparent media of the eye, are carefully distinguished. Previous to this, no questions are put to the patient. The subjective symptoms, with the history of the causes, progress, and duration of the disease are diligently sought after; strict inquiry is made into the present and previous state of his general health, and the diseases which he has had during his life. The diagnosis, prognosis, and treatment of the case are determined in a short conversation between the professor and student. A history of the case is prepared and read at the clinic of the following day. Each student presents his patient to the Collegium every morning, details the changes which have taken place in his symptoms within the last twenty-four hours, and proposes, if he deem it necessary, variations in the treatment. The histories of

all the cases, with the daily reports which are written by the students, are lodged with the Professor, when the patient leaves the clinic. They constitute a part of the probationary trials of candidates for medical degrees.

The same plan of clinical tuition is pursued by the teachers of Clinical Medicine, Surgery, and Obstetrics, in Vienna, and in the majority of the German Universities. It is a system which demands time and patience on the part of the teachers, but is fraught with great advantage to their students. On the completion of their academical course they have obtained in some measure a practical knowledge of their profession, have learned to observe the characters of diseases, and to reason with some accuracy on the modifications required in their treatment. The practical experience and peculiar views of the teachers are, on this plan, readily learned, conversation being an easy method of communicating and acquiring knowledge. It is not the easy matter which students are apt to suppose it to be, to delineate accurately the characters of even a simple ulcer; they first become acquainted with the difficulty when they make attempts to do it, which, when left to their own will, are too often procrastinated. It may be said that a person may be self-taught in his department of knowledge; it may be so; but accurate observation is an attainment so difficult, that lessons will at least be useful in facilitating its acquirement.

M. Louis has commenced teaching clinical medicine on this plan, in the Hospital of La Pitié in Paris. The positions and state of the uterus have long been studied on a nearly similar plan in Paris. The Professor examines the female, *per vaginam*, and details the results of his examination to the students, who, in performing the toucher themselves, endeavour to trace what he has described. These toucher courses are highly instructive, but the attending pupils are generally numerous, and the time too limited for careful examination. Dr. Naegele, Professor of Midwifery in the University of Heidelberg, divides his public class into small parties, which attend the obstetrical clinic by turns. Dr. Naegele having ascertained the position and state of the vagina and uterus, the students examine in succession, and each of them apart communicates the result of his examination to

the Professor, who pronounces upon the accuracy or inaccuracy of his diagnosis.

In ophthalmia tarsi, attended with thickening and induration of the edges of the eyelids, Professor Rosas thinks favourably of the deobstruent efficacy of cicuta. After the crusts, which so often form on the margins of the eyelids in this disease, have been removed by poultices, cicuta is prescribed in the form of lotion, or mixed with weak red precipitate ointment. A solution of muriate of mercury in water, with the addition of some extract of cicuta, is frequently prescribed as an eye lotion.

In granular conjunctiva, which Professor Rosas thinks is of the nature of polypus, the use of acetic acid seems beneficial. Professor Rosas exposes the granulated surface by evert-ing the eyelid, and applies the acid with a camel-hair pencil. The moment that the acid is applied, the granulated surface becomes pale, and this appearance continues for a considerable time. Before allowing the eyelid to invert itself, oil is streaked upon the surface to which the acid was applied, to prevent injury to the eyeball. I have seen the good effects of acetic acid, in a case of sarcomatous eversion of the lower eyelid. Dr. Jaeger's assistant was trying oil of thyme in granular conjunctiva, when I left Vienna.

A number of deep and superficial cancerous looking ulcerations of the eyelids were treated in Professor Rosas's clinic during the winter. In the case of an old man, the disease had destroyed the nasal half of the eyelids of the right eye, exposing the inner half of the eyeball; the conjunctiva bulbi was destroyed, but the sclerotic coat was untouched by the ulceration, this being a membrane, in the opinion of Professor Rosas, seldom found involved in cancer or fungus medullaris of the eye. This patient had been successfully treated in the clinic, on a former occasion, for the same disease, existing to the same extent, and in the same situation, in the left eye. The following are the remedies which Professor Rosas finds most successful in these cases. *R̄. Oxydi arsenici albi, ℥ij; sanguin. draconis, gr. xij; cinnabar. 3ij. m.* This constitutes the pulvis cosmicus. Eight grains of the powder, made into a paste with water or oil, are applied to the ulcer by means of a bit of wood. The indurated surface of the sore being destroyed,

healthy granulation is attempted by the application of laudanum, or Helmont's ointment, which is made with equal parts of Pestrian balsam, extract of cicuta, tincture of opium, and acetate of lead, to eight parts of simple cerate. Extract of cicuta is given internally in the form of pill.

The following case of erysipelas palpebrarum proved fatal from supervening meningitis. The patient, a man about 35 years of age, was received into the clinic of Professor Rosas on the 19th December, 1833. Both eyelids of left side presented a livid swelling, attended with the usual appearances of erysipelatous inflammation. He complained little of pain. The disease had attacked him two days previous to his admission, and he ascribed its origin to the sudden cessation of rheumatism; there was considerable quickness of pulse and fever, with general derangement of the functions; warm dry linen cloths were applied to the eye; his bowels were to be opened by sulphate of magnesia, dissolved in a decoction of mallows; and tepid barley-water was allowed him for ordinary drink. On the 10th he was restless, complained of headach, and talked incoherently; he was bled from the arm; mustard poultices were applied to the feet; and the medicines prescribed on the previous day were continued. On the 11th he was comatose: the bleeding was repeated, and infusion of arnica was prescribed. He died at 3 o'clock in the afternoon. On the 13th the body presented the following post mortem appearances:—Blood flowed plentifully when the skull cap was torn from the dura mater; the arachnoid membrane was highly vascular, thickened, and dim; the substance of the brain was firm, and its vessels turgid; the sinuses, particularly those in the base of the skull, were distended with fluid blood; the ophthalmic artery, on the affected side, was tumefied; the orbital cellular substance was very vascular, and softened in texture; the eyelids were of deep livid colour, thickened, and their surface partially covered with crusts. In the thorax and abdomen no pathological appearances, worthy of notice, were discovered.

Professor Jaeger made trial of acupuncture in the following case of paralysis of some of the muscles in the orbit. The patient was a stout man about 30 years age, and he ascribed the affection of his eye to exposure to cold.

The upper eyelid hung down, covering more than half of right cornea. He was incapable of moving the eyeball upwards, inwards, or outwards. The abductor retained its power, so that he could direct his eye towards the temple; the pupil was greatly dilated, and vision very indistinct. Leeching, blistering, rubefacients, and stimulating plasters, with the internal exhibition of calomel, were tried for several weeks without any amelioration. Professor Jaeger introduced a very slender needle to the depth of nearly an inch, in the direction of the levator palpebrae superioris. The needle was allowed to remain till the patient began to experience smart pain in the orbit, which generally took place in a minute or two after the introduction of the needle. This process was repeated every second or third day for two weeks, when the patient left Vienna without having experienced any benefit. I met him accidentally in the street in a town in Hungary, about six weeks after the first trial of acupuncture, and the symptoms continued the same as when I saw him in Vienna. In some cases of this description, the amaurotic symptoms are probably owing to a rheumatic affection of the neurilemma of the optic nerve. A degree of amaurosis, in the rheumatic ophthalmia, is occasionally met with, apparently from the same cause. In syphilitic diseases of the eye, amblyopic symptoms appear occasionally to be the effect of pressure from diseased periorbital.

Professors Rosas and Jaeger are of opinion, that the conjunctiva bulbi, in its physiological condition at least, partakes more of the characters of serous than of mucous membranes. Dr. Rosas states, in his work on the Eye, that the conjunctiva loses its mucous character and assumes the serous, proportionably to its distance from the margin of the eyelids; that where it covers the cornea it has assumed entirely the serous character; that the conjunctiva, as it approaches the margin of the cornea, becomes smoother, more glancing, and firmer in its texture, and that the conjunctiva bulbi resembles serous membranes in the disposition of its vessels. In accordance with these views of the anatomy of the conjunctiva, rheumatic inflammation of this membrane is of frequent occurrence in Vienna. The students used to name this disease "*pleuritis oculi*." The idiopathic form of the disease is subject to va-

riations from scrofula and other allments; hence conjunctivitis rheumatica, scrofulosa, and other varieties are described. The idiopathic form of the disease appears to be the catarrho-rheumatic ophthalmia of English authors. The conjunctiva may be subject to rheumatic inflammation, but in most of the cases which were pointed out to me as rheumatic conjunctivitis the sclerotica was involved.

In rheumatic ophthalmia, warmed linen cloths are applied to the eye, which are said to be indicated by the patient keeping the orbital region covered with his hand; fluid applications to the eye in this description of ophthalmia are thought improper. If there be much supraorbital, or circumorbital pain, extract of hyoscyamus, or powdered opium, mixed with a little lard, is rubbed on the eyelids or brow. Professor Rosas prefers hyoscyamus to opium in active congestions of the eye or its adjacent parts; hence, in the cases of young people, hyoscyamus is more frequently employed than opium; in old people it is the reverse. Leeches are applied in this disease to the neighbourhood of the eye, but it is seldom found necessary to take blood from the arm. Diaphoretics, as the acetate of ammonia, or the tartrate of antimony dissolved in a decoction of mallows, are found useful. The remedia resolventia, as taraxacum, the triticum repens, the nitras potassae, and other saline preparations, are often prescribed by Professor Rosas, as he supposes that congestion of the liver and vena portarum system produces or favours the continuance of eye diseases. In the milder forms of rheumatic inflammation of the eye, Professor Rosas deems mercury unnecessary; he prescribes it when there is danger of serous exudations. If it be necessary to exhibit anodynes internally, he generally prefers hyoscyamus to opium. When the disease has become chronic, counter irritation, by blisters and tartar emetic ointment, applied behind the ears is had recourse to. A solution of the lapis divinus, with the occasional addition of some tincture of opium, is used as an eye lotion. I never saw solutions of lunar caustic used in any disease of the eye at Vienna, the beneficial effects of which, in conjunctival inflammation, are so universally acknowledged by the surgeons of this country, who are acquainted with eye diseases. A so-

lution of corrosive sublimate is occasionally employed as a lotion.

Acute catarrhal ophthalmia are treated with purgatives, diaphoretics, and local and general bleeding when necessary; tepid water alone, or with the addition of some mucilage of quince seeds and tincture of opium, is used as an eye lotion. In the second period of the inflammation no mucilaginous fluid is thought necessary; astringent solutions remove the disease.

I saw two cases of ophthalmia erysipelatosæ at Vienna, a disease which I never saw in this country. This variety of ophthalmia was characterised by the conjunctiva being elevated into blebs containing yellow transparent fluid, some of them projecting beyond the margins of the eyelids. In one of the cases, the temple of affected side was tumid from erysipelatos inflammation. The pain felt was trivial. Professor Jaeger, in whose house I saw these cases, prescribed the internal use of small doses of tartrate of antimony.

In Professor Rosas's opinion, scrofulous ophthalmia bears all the use of cold local applications; he finds tepid mucilaginous lotions, and warmed linen cloths, more suited to the disease. He finds it occasionally necessary to take away blood by leeches, and he prefers having them applied behind the ears. Counter irritation to the same situation is often deemed useful; if, however, there are glandular swellings in the neck, the irritants are directed to be applied to the shoulders or arms, in case of producing increased excitement of the already irritated parts. Extract of hyoscyamus is found to diminish the intolerance of light and spasm of the eyelids, which are so frequent attendants upon this disease; if not admissible in the form of lotion, the softened extract is applied to the brow. In the more chronic forms of the disease, solutions of some of the preparations of copper are the ordinary remedies; a solution of corrosive sublimate, with the addition of a little laudanum, is thought preferable when there are pustules of the cornea.

Much attention is paid to the constitutional treatment of scrofulous ophthalmia at Vienna. The patient is enjoined to take free exercise in the open air, when the weather is dry; to have his bed and body linens frequently changed, and his lodgings regularly ventilated. His diet is to consist of fresh animal food; fat,

smoked, salted, and pickled meats are to be carefully avoided. Acids, and the sour wines which are so generally in use among the poorer classes of the people in Austria, and potatoes, bread, and coffee, are strictly forbidden. Animal soups, roasted apples and pears, and some of the dried fruits are thought convenient articles of diet.

It is thought that the object in the medical treatment of scrofula is to give energy to the lymphatic system. With this view, a moderate use of drastic purgatives, jalap and senna, for example, of diaphoretics, as the preparations of antimony and ipecacuanha, and of deobstruents, as taraxacum and mercurials, is tried. Narcotics are indicated when there is a high degree of irritation of the lymphatic or nervous system. Among the tonics carbonate of iron is sometimes used. I never knew sulphate of quinine prescribed as a remedy in scrofulous ophthalmia at Vienna.

Professor Rosas has observed that arthritic ophthalmia generally commences in the left eye, and that the disease in many cases does not appear in the other eye till the first attacked has suffered materially. Dr. Rosas has described arthritic inflammation of the conjunctiva as characterised by a peculiar yellowish erysipelatos redness of the margins of the eyelids, by frequently repeated cramps of the orbicular muscle, by severe pain, by exacerbations in cold wet weather, by remissions when the atmosphere is dry and warm, by secretion of acrid tears from the lachrymal gland, and by a peculiar white frothy discharge which appears on the eyelids. In this ophthalmia, the conjunctiva is often in a softened condition, but seldom shows any disposition to secrete pus. Arthritic ophthalmia seems, however, to delight in fixing its seat in the venous system of the eye, and accordingly its most frequent forms are inflammation of the choroid and iris. Congestion of the liver and vena portarum system seems often to exist along with arthritic inflammation of the eye; the disease often appears after suppressed hæmorrhoidal discharge. Arthritic ophthalmia is treated by general and local bleedings, the extent of the inflammation, and the age and constitution of the patient modifying the degree to which they are practised. When the disease has succeeded to suppressed hæmorrhoidal or other habitual discharge, restoration

is to be attempted. Counter-irritation applied to the extremities, and the abstraction of blood, by leeches or cupping, from behind the ear, neck, or shoulders, are often serviceable. To mitigate the supra-orbital pain, Professor Rosas directs powdered opium, mixed with a little saliva, or the acetate of morphia, dissolved in a drop or two of almond oil, to be applied to the supra-orbital region. In all cases the patient is directed to avoid damp air and wetness. The arthritic cachexy is to be combated by improving the state of the digestive organs.

Foreign Medicine.

ACADEMIE DES SCIENCES.

Sitting of the 5th May, 1834.

Analogy between the Egg of a Bird, and the Ovum of Mammalia.

M. DUTROCHET brought up a report in his name, and in the names of M.M. Serres and J. Geoffroy, on a memoir by M. Coste, entitled, *Researches on the Generation of Mammiferous Tribes*. The report ended with the following conclusions: "the monography of the ovology of the rabbit," which is the subject of M. Coste's treatises, has been written with a truly philosophical spirit, and the author has made judicious use of the improvements that the science has made within the last few years. His labours doubtless leave something to be wished for; the facts demonstrated by him do not all bear the stamp of novelty, but amongst them are several discoveries of great importance that we have verified with the author. He has described, with more precision and detail than had before been employed, the different phenomena which take place successively in the ovum, from the period of its impregnation to that of its complete development. By his observations a complete analogy is established between the egg of the bird and the ovum of mammalia, with regard to their principal phenomena. M. Coste thereby deserves the approbation of the Academy; we would propose that he should be encouraged to continue his researches in a science which every day demands more and more the solution of a question of so much interest.

HÔPITAL DES ENFANS MALADES.

A General Review of the Clinical Lectures, delivered by M. BAUDELOCQUE during the three months of January February, and March, of the present year.

Pleuro-pneumony of the Left Lung—No Active Treatment—Cure following an Abundant Diaphoresis on the 13th and 14th Days.

ETIENNE SAUNAR, aged 4 years, of good constitution, had suffered some time from cough, and on the 20th of March was attacked without any apparent cause with fever, accompanied with dyspnoea and pain on the left side of the chest. These symptoms increased with loss of appetite, and on alternate days he suffered with relaxation and constipation. The child was confined to bed, and mere simple diluents were prescribed. On the 27th of March he was admitted into the hospital, and was then suffering from the following symptoms:—orthopnoea; countenance flushed; skin hot and dry; intense dyspnoea; thirst, *souffle tubaire*; and bronchophony; complete absence of respiratory murmur on the right side, that on the left heard louder than natural, and in some situations combined with the râle ronflant; no expectoration; pulse very quick, 144 in a minute; lips dry; tongue wider than natural, and covered with a whitish mucus; no nausea or vomiting; has had no stool for three days. (Four ounces of blood taken from the arm; decoction of milk wort prescribed; two blisters applied to the lower extremities, and an emollient injection.) The patient is very much irritated, continually screaming, no rest during the night.

29th. Decubitus on the left side; dyspnoea continues; voice extremely feeble; cough very troublesome; pulse 140 in a minute; respiration 48; other symptoms the same. (The decoction of milk wort to be discontinued, in lieu of which the decoction of marsh-mallow was ordered, and a dram of the white oxide of antimony prescribed.)

From this to the 1st of April the symptoms continued; decubitus changing sometimes from the right to the left side; the white oxide of antimony was discontinued, and sinapisms were applied to the left side of the chest.

On the 3rd, fourteen days from the com-

mencement of the disease, profuse sweating; cough moist.

From the 3rd to the 8th, the symptoms gradually subsided; respiratory murmur could now be heard equally on both sides of the chest; *souffle tubaire* can still be heard on the summit of the chest; cough loose; skin moist; all the symptoms improved.

Thus he continued,—every symptom by degrees diminished, and on the 20th of April he left the hospital quite well.

In this case, as in the case of rheumatism, as soon as the medicines were discontinued, and the disease left to nature, the patient recovered, without much debility remaining.

Acute Laryngitis resembling Croup—Repeated Applications of Leeches on the anterior part of the Neck without any relief—Death—Morbid Appearances.

—Cabourg, a child five years of age, was admitted into the hospital on the 9th March. It appeared that the mother had died of phthisis at the age of 27, and the father within the last few days at the Hôtel Dieu, from a disease not yet ascertained. The person who came with the child said, for the last three months he had been troubled with cough, which, for the last two days, had greatly increased, with hoarseness and intense dyspnoea, for which the child had not, as yet, had any advice.

On examination at the time of admission, a violet hue was observed on his countenance, orthopnoea with whistling, neck swollen, pain about the region of the throat, and the child complained of a suffocating sensation; continual cough, no expectoration; pulse wiry, 150; respiration 60 in a minute; tonsils enlarged. From percussion or auscultation no morbid sound was apparent, with the exception of the above named whistling; tongue natural; no appetite; slight thirst; intellectual powers perfect. Eight leeches were applied to the sides of the larynx, a laxative clyster was given, and sinapisms applied to the inferior extremities. An emetic, composed of ipecacuanha, was administered. The latter produced vomiting, and two or three liquid evacuations, and there was a free discharge of blood from the leech bites. The symptoms became ameliorated, and the child passed a tranquil night, but the next morning the symptoms returned with great severity.

10th. The same hue is apparent on the countenance; orthopnoea continues; the sonorousness of respiration can be heard from one extremity of the ward to the other; extreme anxiety; pulse 136, tolerably powerful; respiration 56 in a minute; cough followed by opaque mucous expectoration without containing the least traces of false membrane; amygdalæ healthy. (Decoction of marsh-mallow sweetened. Hydr. subm. gr. xv. to be made in three powders.)

During the day a small quantity of milk was allowed, which was no sooner taken than vomited. In the evening the child became restless and agitated; these symptoms were followed by delirium and extreme difficulty of breathing. (Four drops of croton oil were rubbed on the fore part of the neck, and a blister applied on the nape.)

11th. Excessive prostration; violet hue of the countenance continues, lips swollen and livid; whistling respiration; cough feeble, harsh, resembling croup; voice faint; pulse small, 164; respiration 52 in a minute. On asking the patient where he experiences pain, he points to the laryngeal region. On percussion, a clear sound is emitted on either side of the thorax; and from auscultation no positive indication of disease can be discovered. (Six leeches to the neck, two blisters to the thighs; syrup of ipecacuanha two ounces—a spoonful to be taken in coffee every quarter of an hour.)

From the different remedies employed, no amelioration was procured, orthopnoea continued, with delirium, and violent restlessness, the patient lying first on the right, then on the left side, carrying frequently his hand to the larynx, in the hope of removing some foreign obstacle, which appeared to him to obstruct the air passage.

On the 12th, the next morning, imminent asphyxia; great alteration of features; countenance livid; pulse small, thready; and, in an hour and a half from the visit, the patient died.

Examination of the Body twenty-three hours after Death.—External Appearance.

—The body, since death, has lain on its belly; rigidity of the limbs very prominent; livid hue of the countenance; anterior part of the thorax and abdomen blackish; ecchymosis surrounding the leech-bites.

Neck and Chest.—The glottis and epiglottis are considerably swollen and remarkably red, the rima glottidis of course much restricted. Its mucous membrane presents neither infiltration, ulcerations, nor false membranes. The redness continues in the larynx, especially about its superior part, and is only very slight about the trachea and bronchi, on which there is slight purulent exudation; old adhesions of the lungs to the pleura, principally to the left lung, and in its apex are found two small tubercular masses. The tissue of the lungs contains serum, mixed with blood; the remainder of the thoracic viscera healthy. Head not examined.

At the same period last year, a patient of the same age, with precisely the same symptoms, was under the care of M. Baudelocque. The child was attacked in the hospital. Leeches, blisters, &c., were applied, as in this case, but without success; and, on a post mortem examination, every part of the pharynx and larynx was found in a similar state of disease.

These two facts point out to us the inefficacy of local sanguineous evacuations, when practised on the affected organ. In these two cases, the palliation was only temporary, and the symptoms continued to increase. We neglect, at the present day, too much small revulsive bleedings. Ghisi, who was the first to describe the epidemic of croup at Cremona in 1747, stated that general blood-letting was more beneficial than the application of leeches or scarifications on the affected part; and, indeed, it was the only successful method. In very young children, plebotomy can be omitted, and leeches substituted; but they must be applied as far as possible from the affected organ. M. Chauffard, in his *Traité de Médecine Pratique*, quotes a number of cases, which are in favour of this last method, and which confirm the danger of local blood-letting near an affected organ when in its acute stage. We have lately witnessed a case of acute ophthalmia, which became aggravated after the application of leeches to the temples; but, as soon as sanguineous evacuations were had recourse to on the inferior extremities, the disease subsided.

Extraordinary Power of Increasing or Diminishing the Height at will.

M. Velpeau presented to the Académie de

Médecine a man of forty, over whom a vehicle had passed during his childhood. He has the power of increasing or diminishing his height by two inches at will. This lengthening takes place in the pelvis alone, the trochanters are not displaced, the pubis very little; the sacrum alone ascends and descends like a wedge between the ossa ilii.

EXPOSURE OF THE ADULTERATIONS OF DRUGS.

No one could imagine the fraud and villany which are practised in the drug trade, as proved last week before the Medical Committee of the House of Commons. We take credit to ourselves for having, single-handed, repeatedly attacked this nefarious system, which will, and must, be abated. It must be obvious to the meanest capacity, that the most ample acquaintance with science, and the greatest judgment in practice are of no avail, if adulterated or inefficient remedies are substituted for those ordered in prescriptions. It is really deplorable to reflect that, in a case of danger, the medical attendant feels in his breast that he cannot depend on the genuineness of the medicines he prescribes. This is the melancholy fact, however. If a physician recommend some house, where pure medicines may be obtained, he is assailed in the pages of a contemporary, and accused of having made a contract with the proprietor for a per centage system. His reputation and the welfare of his patient are unworthy of the slightest consideration, and he is grossly slandered for daring to protect his own reputation, and save his patient's life.

Reports of Societies.

MEDICO-BOTANICAL SOCIETY OF LONDON.

Tuesday, June 10th, 1834.

MR. JUDD, Professor of Toxicology, in the Chair.

A PAPER was read on the *Convolvulus Jalapa*, which was furnished to the Society by M. Pelletan, which evinced great research, and a full account of all that has been written by botanists on the important medicine above named.

After the paper was concluded, Dr. Sigmond, Dr. Ryan, Dr. Chowne, and Mr. Iliffe addressed the meeting on the medicinal effects of jalap and its adulteration.

This conversation gave rise to remarks on the adulterations of medicines generally, and to the exposures which took place before the Parliamentary Committee during the week. It was universally agreed by all the speakers, that it was extremely difficult, indeed almost impossible, to obtain pure and efficacious medicines, and that the legislature should devise a more efficient mode of examining apothecaries and druggists' shops than the defective state of the law admits at present.

The meeting then adjourned to the 24th, when Professor Burnett will deliver a lecture, after which the session will close.

THE

London Medical & Surgical Journal

Saturday, June 14, 1834.

MEDICAL RELIEF TO THE POOR.

THE Report of the Poor Law Commissioners contains the following passage, which embodies the result of their enquiries into the medical treatment of parish paupers:—

“The out-door relief of the sick is usually effected by a contract with a surgeon, which however, in general, includes only those who are parishioners;—when non-parishioners become chargeable from illness, an order for their removal is obtained, which is suspended until they can perform the journey; in the meantime they are attended by the local surgeon, but at the expense of the parish to which they belong. This has been complained of as a source of great peculation; the surgeon charging a far larger sum than he would have received for attending an independent labourer, or a pauper, in the place of his settlement. On the whole, however, medical attendance seems in general to be adequately supplied, and

economically if we consider only the price and amount of attendance.”

“The country is much indebted to Mr. Smith, of Southam, for his exertions to promote the establishment of dispensaries, for the purpose of enabling the labouring classes to defray, from their own resources, the expense of medical treatment. Some valuable remarks on this subject by the Rev. P. Blakiston and Dr. Calvert will be found in Appendix (C). It appears to us, that great good has already been effected by these dispensaries, and that much more may be effected by them; but we are not prepared to suggest any legislative measures for their encouragement*.”

It is pretty evident, from the guarded language used by the Commissioners in the first portion of this extract, that they were sensible they had but very imperfectly examined this branch of their extensive enquiries, which it must be confessed was of very little importance in comparison to the graver matters they had to animadvert upon. The published extracts from the information they acquired, give us but seven examples of the pay of parish surgeons, and five of these in Sussex; so that we have no means of judging what were the facts which were elicited during their researches. We have the less cause to regret this defect, as Mr. Warburton has very properly directed some very searching questions to the parish authorities upon this subject.

The contracts with parish surgeons has long been a scandal to country practitioners. If there be any truth in the allegations that are commonly made, there is no doubt that the unusual economy in medical matters, in parish management, is the result of an utter disregard to the

quality of the thing purchased, and too often to the respectability of the sellers. In the unworthy degradation of the profession the interests of the poor have been equally compromised.

With respect to the second portion of the foregoing extract we have, for some time, reserved a few observations on the dispensary system, in the hopes of seeing the remarks which the Commissioners received. They are not yet printed, at least we have been unable to procure them. But as our attention has been lately called to certain attempts at establishing self-supporting dispensaries we shall anticipate the subject, and, in the meantime, introduce a few remarks upon the collateral topic of gratuitous medical relief to the poor, to which we have been led by some comments in the last number of the *Quarterly Review*.

Not interfering in general politics it would be unwise in us, as medical journalists, to do more than to admire the singular ingenuity with which every subject is tortured into some bearing upon Tory politics in our celebrated cotemporary.

An acute and just observation of Mr. Sharp, in his admirable *Letters and Essays*, is the text upon which the *Quarterly* undertakes to preach.

"When a child is taken from an opulent mother, she comforts herself by saying, 'I thank God that all that could be done has been done to save it;' but the grief of a poor woman is heightened into agony by the belief that a physician and proper attendance might have preserved her little one. Such thoughts are the harder to bear, because the social affections of the needy are necessarily cherished by the habit of doing those humble services to each other which are rendered to the rich by their menials; and perhaps this necessity alone may counteract the

inevitable, and therefore pardonable, selfishness arising from scanty subsistence."

Upon this touching passage, the truth of which the medical practitioner, whose lot it is to be conversant with the severest physical and moral distresses of our nature, whose habits lead him to reflect where others feel, can best attest, our cotemporary "takes leave to observe, that in London, and in all our great towns, thanks to the high and generous tone of feeling *hitherto* characteristic of the medical profession in this kingdom, the poorest have easy access to the best medical advice, as well as surgical assistance—*gratis*."

To this passage there is but one exception,—all the Toryism implied in that adverb *hitherto*. How far this consolation applies to the ranks a little above the lowest, we stay not to inquire. But the insinuation the reviewer means to imply in disfavour of medical reform, as destructive of the generosity and sympathy of medical practitioners, deserves more especial notice. This hint, the reviewer ingenuously confesses he has received from a pamphlet on *The Medical Profession in England*, which he recommends to the candid attention of Lord Durham and Mr. Warburton. This pamphlet our readers are already acquainted with through the pages of this Journal. Under the impression that nothing is ever gained by slighting or perverting the argument of an adversary, we endeavour to do full justice to our opponents. The argument we are about to notice did not, we admit, strike us as of so much importance as to merit particular attention, till we found it was so highly valued in such an influential quarter. "Suppose," says the author of the pamphlet, "the practice of physic be reduced to a mere trade for lucre—and it is not difficult to conceive

this—nay, it is the inevitable consequence of bringing all the present denomination of practitioners under one head, and giving them all equal rank. . . . Conceive, then, the condition of gentlemen in the profession to be at an end, and the business of physic to have become a mere trade, in which there is a competition of tradesmen to supply the article of advice at the cheapest rate. . . . A person of reputation for the cure of diseases under this free trade system, would not only have no scruples, but would think he did not do himself justice if he forbore to take advantage of such opportunities, *as he who dealt in TIMBER or in COALS would avail himself of the rise in the market to sell his goods.* This is but a short hint at the evils of such a change;—add to them another. *The charitable assistance which is afforded by all branches of the profession to the poor, or to persons in indifferent circumstances, would at once be stopped. For that high character for benevolence which has been cultivated in the profession of physic from the commencement of the institution of the COLLEGE, and has, by the example afforded, been diffused to all branches of medical practitioners, and raised the whole of the profession to a higher state and condition in England than in any other country in Europe will be lost. Each individual will consider that his advice and medicine is his stock in trade against such competition, as will not allow him to dispose of any of it in charity, lest he lose his daily bread."*

We are not at present aware of the date of the first dispensaries. We do believe that when the College was perverting its charter to the establishment of a downright monopoly in the trade of medicine, and when its insolent bearing, now many years ago, engaged the public interest in behalf of the apothecaries, inso-

much that the House of Lords virtually repealed its charter—we do believe that, at the time we allude to, the handful of practitioners constituting the College established a dispensary for the poor as a subterfuge from the unanswerable argument of their opponents against their then oppressive and grinding monopoly. We reproach not the Fellows of the present day with the misdeeds of a past age; but when it is boldly asserted that THE COLLEGE set the example of liberality, we cannot but examine into its pretensions; and when, in the nineteenth century, an advocate of the *rent* abuses of the profession, whom, from his nail, we cannot but recognise*, seriously, or under the mask of seriousness, cautions the public to apprehend the decay of the professional charities, together with the total loss of gentlemen practitioners, in the downfall of insolent and useless distinctions, and in the encouragement and improvement of medical education, it is difficult to restrain our honest indignation within moderate bounds. We shall pursue the subject of Dispensaries in our next.

MEDICAL LAW.

DURING the course of the week the Court of King's Bench has given judgment in the case of Collins v. Colnaghi, to the effect, that a Scotch physician cannot lawfully practise physic in England.

A question of great importance to the public press has been postponed for a second argument next term. The question is how far a *bond-fide* report of what takes place in a court of justice is an authorised publication. We have often abstained from commenting upon reports of coroners' inquests in consequence of the uncertainty of the law. Common sense seems to us to make short work of the argument.

**EXPEDIENCY OF PRINTING THE
MEDICAL EVIDENCE GIVEN BEFORE
THE HOUSE OF COMMONS.**

We hope that Mr. Warburton will report to the House of Commons the progress of the Committee, before the prorogation of Parliament, so that the minutes of the Committee may be made public. We can see no reason why it should not be done in a matter like this, which is purely professional, and it would be very satisfactory to gentlemen in the country, who have considerable anxiety on the subject. It would relieve us from the difficulty under which we labour in being unable to reply to our correspondents without a breach of privilege of Parliament.

Among many communications we received on the progress of Reform, there are two which demand an answer, and these relate to

MR. GUTHRIE'S EVIDENCE.

Gentlemen have written to ask us how we reconcile the statements we have made, that the President of the College of Surgeons was the best advocate and the best witness the College could have had, with the liberal sentiments he has expressed on various occasions. Our reply is, he became the best witness and advocate simply through the liberality of his sentiments, by mentioning every point with perfect openness and candour, by admitting every error into which the College had fallen, and by showing where they were, in his opinion, right, and where they were wrong, without reserve, or without endeavouring to conceal anything. He also showed what had been done, and what they would do if power were granted to them. He not only pointed out every abuse, but the means by which they were in future to be prevented. For instance, after mentioning the various ways in which he had heard it had been proposed to elect the Council, he pointed out the inconveniences that would result from all; and whilst he preferred the present mode, on account of its greater fairness to all classes of persons, he said it was so disagreeable to himself and to most of the Council, that they would be glad if the Committee could find another and a better way of doing it; but that if they could not, they would ensure strict

justice being done, by not allowing the person elected to take his seat at the Council until after the election had been confirmed by the Secretary of State for the Home Department, thus giving time to every man who thought himself aggrieved or passed by to make his appeal. In addition to this, he recommended that all the meetings of the Council, except those for the election of a new Councillor, should be open to the members generally, so that anything under discussion might be publicly known, and thus every member of the Council would stand fairly before the public on his own merits, and abuses could neither be created nor exist. Other points of Reform which Mr. Guthrie recommended we cannot enter into; they extended to every thing connected with the affairs of the College, and, though we differ from him on many points, we are satisfied that the whole of his evidence will be read with great interest when the time comes for its publication.

**HOSPITAL AND PRIVATE MEDICAL
SCHOOLS.**

In another page will be found a Representation from the Bristol Medical School to the indefatigable Chairman of the Parliamentary Committee on Medical Education, to which we request the attention of our readers. Such a proceeding was called for, in consequence of the evidence given by certain lecturers of the London Hospital Schools, which went to show that medical science could only be taught efficiently in their *own* schools, and that "low fees were dishonest." We are not aware of any private lecturer who has been examined, or allowed to answer this allegation; and so far as the recorded evidence goes, it is interested and one-sided. There is a good maxim in our laws—*Audi alteram partem*—and we entertain no doubt but the liberal and upright Chairman will bear this in recollection. In the meantime we cannot help commenting upon and refuting the above evidence. Few will admit that the Examiners and Council of the College of Surgeons, most of whom are teachers, are the only individuals in Great Britain and Ireland who can communicate the best medical instruction! For our own part, we have long entertained the opposite opinion;

and have long since expressed our conviction, that there are as scientific and dexterous operative surgeons, and as good teachers and writers, in different parts of the United Kingdom as in this metropolis. Were it not invidious, we could name physicians and surgeons attached to private schools who have far outstripped many of their metropolitan contemporaries, and have done much more for science. Moreover, we could prove that, so far as the private schools are concerned, they are frequented by those who have entered at the larger schools, and who find it their interest to re-enter the proscribed places of instruction. In attestation of this fact, we may mention, without the slightest vanity, that pupils have entered to our lectures, after having attended the same subjects in larger schools; and we have had them from every large medical school in London. The same fact could be attested by our colleagues, and it is easily explained. The private lecturers are in their own defence indefatigable, are more accessible to students, and are ever ready to give explanations and information. Nearly all the lecturers in the large schools immediately disappear after each lecture, and leave students to have their doubts cleared up as they may. But the real offending of the private schools is the lowness of their fees—*hinc illæ lachrymæ*. It is, no doubt, very dishonest that one school demands eighteen or twenty guineas for anatomy, when another offers it for one-half or one-third of that sum; and so also with respect to the other branches of medical science. This is the real source of dissatisfaction. There are, however, some individuals so antiquated in their notions, and so aristocratic in their dispositions, that they still imagine there ought to be the high fees exacted which were demanded some thirty years since, when there was no competition or rivalry in medical teaching. They forget that a race of younger and more efficient instructors than themselves are in the field; and that these, in accordance with the spirit of the times, are contented with a fair though more moderate remuneration for their labours. The world, too, is so stupid as to patronise the new plan, and hence we have low fees in London, Dublin, and Edinburgh. We remember the good old times when we were “dishonestly” mulct in double the fees now fixed in the Dublin and Edin-

burgh schools; that is to say, we paid four guineas for each six months’ course of lectures, which may now be had for half the amount. Nevertheless, this sum is only one-half of the lowest fee demanded in London, *ergo*, the private schools with us are absolutely dishonest in taking such low fees. We are satisfied that we have said enough to convince Mr. Warburton and the Medical Committee that there are two ways of telling a story, and that the legal maxim, *audi alteram partem*, is accordant with common sense and justice.

REPRESENTATION OF THE MEDICAL SCHOOL OF BRISTOL TO THE MEDICAL COMMITTEE OF THE HOUSE OF COMMONS.

To the Chairman of the Committee on Medical Education.

SIR,—Having reason to believe that the Committee over which you preside are anxious to collect all the information that can be obtained on the present state of medical education, and to give attention to statements of grievances and disadvantages experienced in any department of the profession, we, the undersigned Lecturers of the Bristol Medical School, take the liberty of addressing your Committee on a subject which we consider of vital importance to the success of our Institution, and, consequently, to the interests of medical students in this city.

We do not think it necessary to trouble you with any remarks tending to demonstrate the possibility of completing a medical education beyond the walls of the metropolis, nor shall we urge the advantages which are peculiarly afforded by Bristol for the prosecution of medical study. For information on the latter point we beg to refer to the enclosed prospectus.

The object that we have in view in the present memorial is, to solicit respectfully, but earnestly, that you will take into consideration that regulation of the Council of the Royal College of Surgeons, which prescribes an attendance of six months at one of the hospitals in London, as a necessary condition for obtaining the diploma of the College.

The intention of this regulation was undoubtedly a good one: it was designed to enforce a certain quantum of

practical information, which, according to the ideas of the framers of this regulation, would be accomplished with greater certainty, and with more collateral benefit, in London than elsewhere. Whether this idea was a correct one at the time the regulation was enacted, it is not our business to inquire; but we conceive that the mere fact of the existence of such hospitals as are now common in the provinces, and a knowledge of the mode in which their professional departments are conducted, must be amply sufficient to show that, however superior were the advantages once afforded by metropolitan institutions, that superiority no longer exists. Nay, we might go a step further, and say, that a student will spend a given time at a hospital in the country more profitably than at one in London, for the simple reason, that his examinations of cases in the latter instance must, to a certain extent, be contracted and disturbed by the throng of persons who are no less desirous than himself of extracting the same amount of information from such cases, but this inconvenience rarely or never occurs in provincial institutions.

But were the regulation in question *superfluous* only, we should feel some hesitation in troubling your Committee with our sentiments on the subject. We regret, however, to say, that its operation is actually injurious, by interfering in those branches of provincial education which have no immediate connexion with hospital attendance. When a student knows that however diligently he may toil in the prosecution of his studies under provincial teachers, his course cannot be completed without a certain residence in London, he is induced to underrate the opportunities in his present possession, and to delay the pursuit of various branches of knowledge, until he shall have repaired to a situation where he imagines he shall imbibe instruction of a more profitable character than can be obtained in his present circumstances. In the meantime he neglects the acquisition of those fundamental principles of medical science which are absolutely essential to the utility of a residence in London, and fall into habits of idleness and listlessness, or at best of superficial observation, which would render him incapable of making the acquisition that he needs during the prescribed residence, even if the time were sufficient for the purpose,

but which is very far from being the case. In order, however, to obtain a certificate of his capability of practising he adopts a pernicious method but too common among students in London, that of resorting to a private tutor who, although he may, by dint of what is technically termed *grinding* or *cramming*, enable his pupil to answer a number of interrogatories before a Board of Examiners, cannot be expected to qualify him for the important and difficult duties of a medical practitioner.

When to the foregoing considerations we add the well known fact, that vast numbers of promising young men have had their characters, their usefulness, and their peace of mind irreparably ruined by even a brief sojourn in the capital, where practices of immorality and licentiousness may be pursued with such facility, and with so little immediate disgrace; when we urge that a heavy expenditure is incurred by students, in addition to that which medical education must entail under any circumstances; and, finally, when we submit, that the regulation implies an invidious distinction between the hospital teachers in the metropolis and those in the provinces, we entertain great hopes that your Committee will think it right to recommend to the legislature, that the obnoxious regulation be annulled.

We have the honour to remain, Sir,
Your obedient servants,

HENRY RILEY, M.D.

J. A. SYMONDS, M.D.

WILLIAM HETLING, M.R.C.S., Surgeon to the Bristol Infirmary.

HENRY CLARK, M.R.C.S., &c.

J. C. SWAYNE, M.R.C.S., &c.

G. D. FRIPP, M.R.C.S., Surgeon to the Bristol General Hospital

WILLIAM HERAPATH.

SAMUEL ROOTSEY, F.L.S.

To HENRY WARBURTON, Esq. M.P., &c.,
Chairman of the Committee on Medical Education, House of Commons, London.

ARGUMENTS MADE ON THE DIFFERENT THESES WHICH WERE WRITTEN FOR THE CLINICAL CHAIR OF MIDWIFERY, BY COLOMBE, DUBOIS, VELPEAU, AND BAGIGNAN.

Extracted from the Lancette Française.

THE first thesis by M. L. Colombe—on Delivery.

M. Colombe called delivery the completion of labour.

M. Dubois disputed this definition, because, after the expulsion of the placenta, there still remained some clots of blood to be discharged,

M. Dubois blamed M. Colombe for making a scholastic distinction of the three periods in the separation of the placenta. You have even, says he, allowed of it, by saying that you would distinguish these periods by the character of the pains.

M. Colombe.—I have not pretended to distinguish thus the times of separation, but only if there is or not adherence of the placenta. We might as well make ten periods as two, three, four, or five. Thus in prolapsus, we can divide into as many lines (laughter).

M. Velpeau.—You say that adhesions of the placenta are less at the commencement and termination of pregnancy. On what do you found this opinion? Is it on the experiments of Alph. Leroy?

M. Colombe.—I regard but little experiments; it is from practical observation.

M. Velpeau.—If at the commencement of pregnancy the fetus is expelled, it depends on the state of the neck of the uterus, but, on the contrary, if at the termination, it is from distension of this organ. When we examine the fetus in utero, we find the adhesions the same at all periods; the placenta, however, is not, as you have described, of smaller size proportionally in the middle than in the last months of utero-gestation.

M. Colombe.—You are speaking of the embryology, which is not a part of delivery.

M. Velpeau.—You say in page 6 of your thesis, that the vessels of the placenta, in the termination of pregnancy, become obliterated; this is not the case, they are in the same state; they are changed only in number and volume. What is your opinion on the chatonnement of the placenta? [hour-glass contraction.]

M. Colombe.—Before giving an opinion, it would be necessary to see many of them; I can at present give you only the opinions of authors.

M. Velpeau.—On spasmodic obstruction of the neck of the uterus—do you speak of the external or internal orifice?

M. Colombe.—Of the external.

M. Velpeau.—I deny that this orifice has the power of contraction so as to prevent delivery. The neck in this case is dragged towards the vulva; the hand is introduced into its cavity, sometimes even to the extent of four or five inches, without entering the cavity of the uterus; the contraction is at the internal orifice; you have mistaken one for the other.

M. Colombe.—Hervé relates a case in which the external orifice was so much contracted after delivery, that he was unable to introduce a stylet.

M. Velpeau.—That is impossible in the first twenty-four hours; the two orifices have always been confounded.

M. Colombe.—Then the error has been common to Desormeaux and many others.

M. Velpeau.—My opinion on the chatonnement of the placenta is the following: it happens not unfrequently, I have often seen it;

it is distinct from contraction of the internal orifice. In utero-tubal pregnancies, the chatonnement is in the angle of the womb; it exists then in three cavities—1st, that of the neck; 2nd, that of the uterus; 3rd, that of the chatonnement.

M. Colombe.—I have seen but one kind of chatonnement, and I have never witnessed particular pouches.

M. Velpeau.—In floodings that take place before delivery the precept is immediate delivery. Why do you say in page 24, that it is necessary to wait, and introduce the hand only if the woman is not too feeble.

M. Colombe.—I have seen attempts at delivery prove fatal.

M. Velpeau.—Doubtless it does not always prevent death.

M. Colombe.—But it hastens death! I spoke, in fact, of the means to facilitate the contraction of the uterus, in cases of inactive contraction.

M. Velpeau.—The best plan is to deliver.

M. Colombe.—That is if there is danger of death.

M. Velpeau.—We must deliver before it takes place.

M. Colombe.—If the patient is very weak you kill her.

M. Velpeau.—What do you do then?

M. Colombe.—I wait.

M. Velpeau.—The patient dies.

The second thesis, read by M. Dubois.—What are the best means to be adopted in cases of narrowness of the pelvis? (Arguments between M. Velpeau and M. Dubois.)

M. Velpeau.—Page 83 and 84, you say,—If a calculus complicates the labour, it is necessary to thrust it back above the head of the child, by driving back the head at the same time, or as well to perform the operation of lithotomy, as under any other circumstance.

M. Dubois.—It is not I who has recommended this mode of proceeding: and if you continue the paragraph, you will find that I have explained it in another way.

M. Velpeau.—You have stated it positively as a fact in those cases in which the forceps are insufficient. What method should you prefer, then?

M. Dubois.—The high apparatus recommended is only possible when the head is not engaged in the pelvis; and then not necessary. When engaged in the pelvic cavity, it is impossible to have recourse to it with any beneficial result.

M. Velpeau.—You might have said that with advantage in your thesis.

You have spoken, page 76, of tumours not inherent to the conformation of the pelvis: in cases of obturation by a tumour in premature labour, does it appear to you applicable?

M. Dubois.—You confound two things together. I have said, first, that if contraction was owing to a permanent cause, we must

proceed as in cases of deformation of the pelvis; secondly, if the tumour changed in volume from one day to another, or in the course of nine months, then artificial means must be had recourse to for effecting premature labour.

M. Velpeau.—~~Osseous~~ tumours are very various; you have spoken of only two. In the case of an osseous prolongment in the form of the styloid apophyse behind the pubis, would it be essential to produce artificial labour?

M. Dubois.—It is difficult for me not to reply, but I shall not enter into all the by-roads of this question. What I have said of permanent contraction generally takes place, though not always: it is impossible to enter into the details.

M. Velpeau.—You might have mentioned them to a certain extent.

M. Dubois.—My thesis already contains 85 pages.

M. Velpeau.—Page 70, you say,—when the pelvis is less than two inches, and the infant is dead, the Cæsarean operation is indicated; but if the child is dead, the operation that you speak of is unnecessarily dangerous.

M. Dubois.—In these cases it is impossible to extract the fœtus by the natural passage, without equally endangering the life of the patient.

M. Velpeau.—Well, you say if the head only remains, and the pelvis be less than two inches, it must be abandoned.

M. Dubois.—There is in such cases a great difference. When the fœtus remains entire in the cavity, it putrefies, and causes much greater danger than if the head alone remained.

M. Velpeau.—Then, when the fœtus is entire, is it not best to extract it by pieces?

M. Dubois.—There is no comparison; the danger of the version and of the extraction of the parts adds to the danger of the head remaining in the cavity, and is much greater than the Cæsarean operation.

M. Velpeau.—I believe your opinion to be too absolute. In the case of the pelvis being three inches and a half, and the fœtus dead, you say, page 25, that it is necessary to wait; but the death of the infant is the very reason you should not wait, for the pains become less severe, and there is not sufficient power for its expulsion.

M. Dubois.—You do not finish my phrase; I add, "or you must be guided by the same rules as if the pelvis was naturally formed." I bear all the responsibility of my phrase.

M. Velpeau.—Have you said that it is necessary to wait?

M. Dubois.—As in ordinary labour.

M. Velpeau.—It is necessary to proceed in its extraction.

M. Dubois.—I do not suppose to have finished. I persist in what I have stated.

M. Velpeau.—We differ in opinion.

M. Dubois.—It is an error to imagine the work is over, because the child is dead;

nevertheless, I beg you will permit me to keep my opinion.

M. Velpeau.—And I shall keep mine. (*Laughter.*)

M. Velpeau.—You perforate and empty the contents of the cranium when the diameter of the pelvis is three inches and a half. I am astonished to hear you speak so frequently of perforation. What do you think, then, of cephalotribe?—it is sufficient when the pelvis has three inches and a quarter to three inches and a half.

M. Dubois.—The application of the cephalotribe is very difficult; impossible even in the case of three inches. Have you applied it?

M. Velpeau.—Yes, once. It offers less danger than perforating the skull.

M. Dubois.—I may say its application is impossible, when I know the difficulty we find in the employment of the forceps, in those cases in which we are compelled to place the branches of the forceps otherwise than natural. There is no comparison between it and the easy operation of perforating the skull.

M. Velpeau.—When you have perforated the cranium, why do you not use in preference the cephalotribe to the forceps? Besides, I do not agree that its use is more dangerous than the forceps. One of our colleagues has employed it many times, in which the pelvis has not been three inches.

M. Dubois.—It is very difficult; perforation is less painful.

M. Velpeau.—So you perforate, and I crush. (*Laughter.*)

M. Velpeau.—You require for the state of premature labour 1st, that the woman is in good health; 2nd, that she is primiparous; 3rd, that the two preceding labours have been impossible. But you acknowledge yourself that it is essential for the first labour to relax the parts; but I have seen several women in whom premature labour has not been, after repeated efforts, produced, and in whom parturition took place at the usual term. Is this your opinion?

M. Dubois.—Yes, in general; I have, in fact, only to quote Jœrghe. This last objection is not serious; but if it were always true that after one or two mutilated infants, the woman could be naturally delivered, it would be necessary to condemn altogether premature labour. I have cited Smellie as an authority for the provocation of delivery.

M. Velpeau.—Your reasons do not point out the necessity for premature accouchement. A large head presents to the side of the largest or narrowest pelvis; as to the exact dimensions, it is difficult to ascertain by a few lines; you cannot know then whether delivery will take place, and not any of your arguments are convincing; besides in particular epochs of utero-gestation there is an uncertainty as to the diameter of the head.

The third thesis by M. Velpeau.—Convul-

sions in women during pregnancy, at the time of labour, and after delivery.

M. Dubois.—Your thesis contains many inexactitudes.

M. Velpeau.—Without doubt there are many that I should not have wished it to contain; however I have corrected many of them.

M. Dubois.—I attach, in fact, *little*, very *little* importance to this objection.

M. Dubois.—Page 11 you mention a case of pretended convulsion of the uterus, taken from the thesis of M. Baudelocque; there is some contradiction between you in the manner of explaining it, for it is evident that the symptoms resulted from muscular contraction.

M. Velpeau.—I do not see the point of this contradiction; I have given the opinion of M. Baudelocque, who does not admit of the convulsions of the uterus. I added that there might be not only convulsions of muscles, but of the intestines and uterus.

M. Dubois.—I believe that uterine convulsions would not have this effect.

M. Velpeau.—Also I have stated that he exaggerated the case; I add that the fact of Pacond, who has seen after death the uterus to be the seat of real movements and violent agitation, is much more extraordinary.

The fourth thesis by M. Bagignan.—In cases of faulty presentation of the foetus, what is best to be done?

The arguments on this essay were strongly contested by Dubois, Bagignan, and Velpeau; the want of space prevents us from continuing their argumentation.

LITERARY INTELLIGENCE.

In July will be published a new edition of Mr. Wardrop's *Morbid Anatomy of the Human Eye*. 2 vols. royal 8vo.

The price will be considerably less than the former edition; but the same regard will

be paid to the fidelity and beauty of the colouring of the plates, the whole being executed under the superintendence of the Author.

CORRESPONDENTS.

We shall be happy to comply with the wish of our Glasgow correspondent.

Dr. Stokes's Lecture.—Numerous inquirers, Medicus, A. C. T., a General Practitioner, Zeno, &c. will find the best reply we can give in the present number.

Medicus.—The adulterations of drugs are noticed in another page.

A Reformer.—The provincial lecturers and hospital attendants will be examined, but not this session, as Parliament will be prorogued on the 2nd of July. The Irish and Scotch corporations also stand over. The medical officers of hospitals and dispensaries would be examined were they not required to furnish written evidence.

A Parish Surgeon.—The remuneration of parish surgeons ought to be increased, and fixed in proportion to the amount of the poor.

Galen.—It is not easy to pass a law against empirics, as the upper and middle classes employ them as well as the community. It is very true they commit great slaughter and do incalculable mischief.

A Chemist.—It is very probable that chemists and druggists will be obliged to study *materia medica* and pharmacy, and be confined to preparing prescriptions.

Mr. Helling's communication has been received.

Errata.—In page 604, col. 2, line 40, for increased *read* decreased; in page 605, col. 1, line 35, for primoparous *read* primiparous.

VOL. V.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE XCIV., DELIVERED APRIL 24, 1833.

GENTLEMEN,—This evening I will make a few observations on *wounds of the abdomen*; and it may first be remarked, that those which do not extend through the peritoneum are not attended with any peculiarity, and consequently are to be treated on the principles applicable to wounds in general. In other examples of deeper injury, in which the peritoneum is pierced, and the cavity of the abdomen penetrated, even if the wound heal favourably, it may leave a cicatrix that will sometimes become the seat of a hernial protrusion, if not supported with a bandage.

Severe contusions of the skin and muscles of the belly without any wound, are also sometimes followed by a gradual yielding of the parts to the pressure of the viscera, and, in this manner, considerable swellings, termed by the French *enterations*, may be produced.

A cannon ball, when nearly spent, if it strikes the abdomen obliquely, may rupture the muscles and their aponeuroses, and a protrusion of the viscera be the result, though the skin, on account of its greater elasticity, may continue unbroken. Accidents of this kind, however, are for the most part immediately fatal.

Gentlemen,—you should also be aware that punctured wounds, or violent blows on the belly, may give rise to the formation of matter in the sheath of the rectus muscle, a case in which an early and a depending opening is always required.

A contusion of the hypogastric region, when the bladder is full of urine, will burst that viscus, and occasion a most dangerous extravasation of urine; such as is very apt to give rise to a fatal attack of peritonitis, notwith-

standing the prompt use of the catheter, and every aid which it is in the power of the surgeon to afford.

Penetrating wounds of the abdomen, attended with injury of parts of importance, are frequently followed by a small, feeble, contracted pulse, pallid countenance, cold extremities, great and sudden prostration of strength, vomiting, spasmodic affections, and other alarming symptoms. These may indeed arise in timid, nervous subjects, without any injury of important organs; but, unless they soon subside, you will have reason to suspect something more than the wound of ordinary parts.

Generally speaking, unless the wound be large, attended with protrusion of the viscera, or discharge of bile or intestinal matter from the external opening, you cannot at first give any positive opinion about the depth and nature of the injury.

But, gentlemen, you will sometimes gain information from certain symptoms, denoting the injury of particular viscera; as vomiting of blood when the stomach is pierced, discharge of blood per *anum* when the bowels are wounded, or the evacuation of bloody urine when the bladder or kidney has suffered.

From what has been already explained, gentlemen, it must be manifest to you, that, although superficial wounds of the belly are not attended with any great peculiarity, this is not the case with such as penetrate that cavity. Here various sources of peril occur, depending partly upon the chance of internal hæmorrhage, or extravasation of the contents of the viscera, but, in a still greater degree, upon the tendency of the peritoneum, when subjected to irritation, to become extensively inflamed. With the exception of such patients as die instantaneously, or in a few hours, from internal bleeding, nine-tenths of those, who die from penetrating wounds of the abdomen, are cut off by peritonitis. In fact, those who die after a moderate effusion of blood, or from the escape of the contents of the bowels into the cavity of the peritoneum, really die of peritoneal inflammation. Hence, the lancet is one of the principal means on which you are to rely in the treatment, which must indeed be rigorously antiphlogistic.

Wounds of the Belly are sometimes attended with protrusion of the viscera. If these be uninjured, the sooner they are reduced the better. The protruded parts are usually portions of bowel, or omentum. In the reduction of them, the abdominal muscles are to be relaxed, and the mesentery is to be returned before the bowel, and the intestine before the omentum. Rather than injure the viscera by too much pressure, I recommend you, if necessary, to enlarge the wound, due regard being paid, in making the incision, to the situation of the epigastric artery.

Formerly, gentlemen, a regular account was given in books and lectures of the manner of sewing up wounds of the belly, under the title of *gastrophic*, which was generally a kind of quill suture, much more ingenious than useful, or even warrantable. But modern surgeons, when they are obliged to have recourse to sutures for wounds of the abdomen, prefer to the piece of ingenuity which I have mentioned, the common interrupted suture, and make as few stitches as possible. Without absolutely rejecting sutures altogether, they employ them only in cases of necessity, and trust very much to the united operation of position, bandages, and adhesive plaster, assisted by antiphlogistic measures.

Then, gentlemen, you may meet with other wounds of the belly, in which the viscera not only protrude, but are cut or torn. When a portion of intestine was wounded, it was formerly the custom to sew it up with great precision, and with as much coolness as if it were only a piece of leather. This practice has now, I believe, few or no advocates. It is obvious, gentlemen, that when the opening in the bowel is so small as to be entirely closed up by the protrusion of the villous coat, the suture must be useless. In operations for hernia, the bowel is sometimes accidentally wounded, and the feces pass through the aperture: such an accident has happened in the practice of several surgeons of eminence, who immediately surrounded the opening with a piece of silk, and no harm ensued. Of course the ends of the silk should be cut off, experience proving that the small noose which is left always finds its way into the intestinal canal, and is voided with the feces.

Were a bowel more extensively cut, certainly not more than one stitch should be employed for keeping the ends of the bowel near each other; indeed the mesentery itself answers this purpose; and therefore some doubts may be entertained about the propriety of a suture at all, especially when you recollect that the very nature of the process, by which the reparation of a wounded bowel is accomplished, seems hardly capable of being at all promoted by sutures. In fact, such an injury is accompanied with an inversion and protrusion of the mucous coat, which is scarcely susceptible of the adhesive inflammation. The edges of the wound, I may also observe, can never be brought together with accuracy; and the re-

pair is effected through the medium of the surrounding parts, that is to say, by the adhesions, which the peritoneal coat of the bowel contracts to the great sac of the peritoneum, or to the productions of this membrane, constituting the outer covering of the other viscera.

The right plan, I believe, therefore, is that of avoiding as much as possible the employment of sutures; at all events, I should never apply more than a single stitch of fine thread or silk. Then the bowel should be reduced, and the external opening dressed superficially and lightly, but not very strictly closed. The intestine in a few hours will become adherent to the peritoneum near the external wound, and, through this, any intestinal matter effused will find an outlet. Then, in proportion as the feces resume their natural course, the external wound may be allowed to heal up. The bowel ought always to be reduced as speedily as possible, whether you use a suture or not; and, for this purpose, if necessary, the external wound is to be dilated. The rest of the treatment consists in antiphlogistic means, especially bleeding, leeches, quietude, and abstinence. As for the dressings, I think they cannot be too light, simple, and superficial.

The chance of effusion in the abdomen, gentlemen, is much diminished by the compact manner in which all the viscera and their various surfaces lie in close contact.

Injury of the Viscera without protrusion.—I have already specified a few symptoms denoting the injury of particular viscera. Frequently, however, we remain uncertain about the precise nature of the wounded parts, especially in the beginning of the case. However, this is of no practical consequence, because it is our duty to employ rigorous antiphlogistic treatment, whether the viscera be wounded or not.

Wounds of the small intestines are well known to be more dangerous than those of the large, and the nearer the injury is to the pylorus the greater is the risk. Such cases are also more frequently followed by extravasation. Deep wounds of the liver are alleged to be as fatal as those of the heart itself. Many recoveries from wounds of the stomach are upon record.

Gentlemen, I have mentioned various considerations, rendering it questionable whether you should ever stitch a protruded and wounded bowel; but, when there is no protrusion, no man in his senses would think of ripping open the patient, to perform any experiment of this kind. Indeed, you can rarely know at first whether the intestine is wounded or not, and afterwards when such a wound is denoted by particular symptoms, the bowel has generally had time to become completely fixed by adhesions. Here you should trust to other means,—the resources of nature, assisted by the lancet, abstinence, perfect quietude, and other antiphlogistic remedies.

With respect to the dressings, they should

always be light and simple. If intestinal matter show a tendency to pass by the wound, you should pay great attention to cleanliness, and to maintaining a ready outlet for such matter, until it resumes its natural course, which it will mostly do after a short time, if the patient live through the first perils.

Extravasation of bile, or urine, amongst the bowels, will give rise to fatal peritonitis, and the same consequence is frequently produced by effusion of intestinal matter, unless it happen to be bounded by the adhesive inflammation. If, immediately after a wound of the belly, and its contents, it is the compact state of the contained and containing parts, which at first prevents extravasation, it is that salutary process, the adhesive inflammation, which afterwards renders the occurrence either quite impossible, or bounds and circumscribes the effusion, if it should take place.

It is only under the following circumstances, that the contents of the intestines are likely to be effused. First, when the gut is full, the wound extensive, and air or blood lies near the opening. An extravasation, also, more frequently follows the rupture of the bowels by blows, than the injury of them by wounds.

When an extravasation is perceived in the first instance, a part of the wound should be left unclosed, and the patient placed in a position that will favour the flow of the matter out. Here antiphlogistic treatment is the main hope.

The *Psoas Abscess*, or *lumbar abscess*, is a collection of matter formed in the cellular substance of the loins, behind the peritoneum, and descending in the course of the psoas muscle, until it produces a swelling below or above Poupart's ligament, or glides under the fascia of the thigh. The disease furnishes the best illustration of the nature of large chronic abscesses, and especially of those which are usually regarded as scrofulous. It begins with slight uneasiness in the loins, and a weakness in walking, but no acute pain may have been experienced, though the matter be already copious enough to produce an external swelling. By degrees, however, the quantity of matter becomes very considerable, producing a sense of tension and weight about the loins, pain shooting down the lower extremity, and some degree of hectic disturbance of the system. As I have said, the abscess may form a swelling below Poupart's ligament, or above it; or make its way down the thigh under the femoral fascia. In a few cases it descends into the pelvis, whence it passes through the sacro-schiatric foramen, and forms a swelling near the anus.

Lumbar abscess may or may not be combined with caries of the vertebrae; and the disease of the bone may be either the cause or the accidental accompaniment of the collection of matter. When joined with caries of the bodies of the vertebrae, you may have paralysis of the lower extremities; and then, I believe, the affection of the bones is the pri-

mary complaint, and one of a scrofulous nature. Generally speaking, however, even when a lumbar abscess is joined with disease of the vertebrae, there is no paralysis, and then you may conclude that, in all probability, the affection of the bones is secondary. At the same time, I ought to mention, that my friend, Mr. Brodie, is led by his experience to believe, that lumbar abscess is rarely the primary disease, but originates from caries of the vertebrae.

Gentlemen, from explanations already delivered in previous lectures, you are aware that it is the disposition of lumbar and other chronic abscesses to begin very slowly and insidiously, and to increase in the same way, until, from containing a few ounces of matter, they include at last several quarts. The matter of a lumbar abscess commonly presents flakes of a curdy substance, like those seen in other scrofulous abscesses; and the whole cavity in which it collects is lined by a membrane called *the cyst of the abscess*, which has somewhat the appearance of a mucous membrane, and is the organ by which, after the disease is established, the matter continues to be incessantly undergoing secretion and absorption. The extent of the surface of such a cyst may well be conceived, when you recollect that the lumbar abscess sometimes contains a gallon of matter. Here, gentlemen, you see a specimen of a cyst of a considerable psoas abscess: it looks like a membranous bag of ample size. Until the quantity of matter is enough to produce an external swelling and fluctuation, you rarely have any positive knowledge of the existence of the disease, which is often mistaken for rheumatism.

I have seen several lumbar abscesses, the swelling of which in the bend of the groin more or less resembled that of a hernia, and was attended with impulse when the patient coughed. One case was lately brought to my house: there was a small soft prominent tumour, with impulse, near the groin, but rather more towards the ilium than the place of a hernia, and accompanied by a larger swelling, — evidently an abscess behind the os innominatum. I recommended the tumour behind to be opened, when, if it had a communication with that in the thigh, the latter would subside, and indicate, at all events, the nature of the case. Another surgeon of great experience advised the introduction of a needle into the femoral tumour, in order to learn the quality of its contents.

Attempts have been made to disperse lumbar abscesses by exciting the action of the absorbents, by emetics, blistering the surface of the swelling, and the employment of purgatives. The plan has been attended with little success. Now, as it is the nature of lumbar and all chronic abscesses to become larger and larger, and sometimes to attain vast magnitude before they burst, it is, I think, a good general rule to open them as soon as a fluctuation can be plainly distinguished. It is found, however, that opening a considerable lumbar abscess is frequently followed by a violent and even fatal

attack of *irritative fever*; and hence some caution is requisite if the tumour be large. In fact, when you puncture the abscess, discharge its contents, and leave the opening unclosed, the cyst sometimes inflames over its whole extent, and the patient now suffers that violent derangement of the system, excited by any fresh irritation operating upon a hectic constitution, which is well known by the name of *irritative fever*.

The knowledge of this fact, gentlemen, made surgeons fearful of following this practice when the cyst was of considerable size. Hence arose the method of introducing a seton across the tumour, and letting the matter escape gradually; and Mr. Abernethy's more successful way of letting out the matter by a puncture, and then closing it with adhesive plaister, and healing it by the first intention. The skin is to be drawn to one side, the lancet introduced, and the matter having been discharged, the skin is allowed to resume its natural place again. Thus the opening in the skin and the fascia and cyst do not afterwards correspond, and the admission of air is more likely to be excluded. The cyst remains some time undistended—it has an opportunity of contracting—and, as soon as a certain quantity of matter accumulates again, the same proceedings are repeated.

With such treatment you will have to combine the administration of tonic and alterative medicines, and especially such as are found to be the best for scrofulous constitutions in a state of hectic. After the abscess has become very small, blistering the skin, or rubbing the skin freely with the hydriodate of potash ointment, will sometimes promote the dispersion of the remains of it. If the vertebræ should be diseased, counter-irritation will be advisable; especially an issue or blister kept open.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XXIV.

Recapitulation—Preservation of Function with Organic Disease—Application of the Laws of Development—Vicarious Action of Parts—Importance of Pathology to Phrenology—Diagnosis of Local Disease of the Brain—Opinions of Bouillaud, Serres, and Foville—Influence of the Optic Thalami and Corpus Striatum on the Motions of the Extremities—Researches of Andral—Diagnosis of Disease of the Cerebellum—Connection with the Generative System.

GENTLEMEN,—We were occupied at our last lecture in considering some of the phenomena of partial encephalitis, by which is generally meant, a localized inflammation of the deep-seated parts of the brain; because superficial inflammation of the cerebral substance is very

rarely partial. I endeavoured to show that the diagnosis of this local encephalitis was to be drawn, in a great measure, from the occurrence of pain and muscular affections of *one side of the body*: in other words, that the phenomena of this disease were partial, so as to give us at once a distinction between general and partial inflammation of the brain. In cases of general inflammation, we have convulsions of both sides, delirium, and coma; in the partial form these symptoms are absent until complication takes place. Thus the supervention of delirium, or of convulsions on both sides, in a case where previously the signs of only *partial* encephalitis existed, would point out, in all probability, an extension of disease to the opposite hemisphere. I also endeavoured to point out the different modes in which partial encephalitis might be accompanied with symptoms of a general character, or affecting both sides; that there might be a co-existing inflammation of the membranes; or that the pressure of the diseased on the healthy hemisphere of the brain might be the cause of the complication. I stated, that some of the most remarkable cases of extensive destruction of the brain, without perceptible injury of the mental powers, were those in which a traumatic opening in the skull gave full scope to the swollen parts, and obviated the effects of pressure on the sound hemisphere. I also observed, that, in cases of local affections of the head, there are two causes which have a tendency to produce general symptoms. One of these is the cause which determines the pain and muscular affection of the opposite side; the other is the general determination of blood to the head; so that we may have cases in which the *actual inflammation* is limited to a part of one hemisphere, and yet, from the general determination of blood to the head, we may have coma and general symptoms.

To return again to the interesting consideration of great loss of cerebral substance with preservation of intellect, I have to remark, that this circumstance is one which some persons might quote against the opinion that the brain was the organ of intelligence; and I believe this fact has been laid hold of by the opponents of phrenology, and put forward as a powerful argument against the truth of its doctrines. Thus, for instance, in the case of Mr. O'Halloran's patient, who lost a large portion of one hemisphere, and yet, with all this mischief, the powers of the intellect remained unimpaired; it would not seem strange if a person should say, here is vast destruction of substance without any lesion of intelligence: how then can the brain be considered as the organ of thought? But let us look at this matter in its true point of view. In the first place, it is to be remembered that cases like this are rare,—that they are to be considered as the exception and not as the rule. I have already shown you, that it is a law in pathology that lesion of structure and lesion of function are not always commensurate. This

law applies to the brain as well as to all the other organs. To say that the brain was not the organ of intelligence, because in cases of extensive cerebral disease that intelligence was preserved, is false reasoning. A man will digest with a cancerous stomach;—is it to be argued from this, that the stomach is not the organ of digestion? I have seen the liver completely burrowed by abscesses, yet the gall-bladder was full of healthy bile. I have seen one lung completely obliterated, and yet the respirations only sixteen in the minute, and the face without lividity. What do these facts prove? Not that the health of organs is of no consequence, but that with great disease there may be little injury of function.

By reference to the original laws of organisation, we may (in some cases at least) arrive at an explanation of this fact. You know that organs are primitively double; and we find, that though the fusion at the median line is produced by development, yet that the symmetrical halves still, to a certain degree, preserve their individuality. Thus we see how the laws of organisation affect the phenomena of disease, and recognise a provision, acting from the first moment of existence, against the accidents of far distant disease.

Now, admitting that the brain is the organ of thought, we may suppose that, as in case of partial obstruction of the lung from inflammation, the remainder of the organ takes on an increased action, so as to supply the place of that which has been injured or destroyed. We know, that if one lung be hepatised the other takes on its functions, and carries on the process of respiration for a time. That this is the case, is shown, first by life being continued, and secondly by the stethoscope, which informs us that the respiration of the lung, which has a double duty thrown upon it, is remarkably intense, proving the force of its action; and it has been further established, that the lung which thus takes on a supplemental action may become enlarged and hypertrophied. May not this also occur in the brain? There is no reason why such a pathological phenomenon, occurring in one viscus, may not also take place in another. But the opponents of phrenology say, supposing the organ of causation to be destroyed, how can the person continue to reason? It strikes me that the only way in which we can account for this is, by supposing that other parts of the brain take on the functions of those which have been injured or destroyed. Nor is there anything extraordinary or anomalous in such a supposition. We see, almost every day, examples of this kind. We see that in certain diseased states of the liver, accompanied by suppression of its secretion, its functions are assumed by other parts, and bile continues to be separated from the blood by the kidneys, salivary glands, and by the cutaneous exhalants. Here is a remarkable case, in which the glands and other parts take on the performance of a function totally different from that in which they are ordinarily employed. We find, also, that

when the urinary organs are obstructed, urine, or its principles, are discovered in parts of the system where we should not at all expect them. Thus we have a very remarkable case detailed in the American Journal of the Medical Sciences, in which we find that a young female, who laboured under paralysis of the urinary organs, discharged urea from almost every part of the body, even from the ears. Neither is there anything very extraordinary in this. In several instances of suppression of the menstrual discharge, do we not see a vicarious secretion taking place from the surfaces of parts the most distant, and unconnected with the uterine system? It is a well established law, that when the functions of organs are suspended or destroyed, other parts will often take on the action of the injured viscus. Now, supposing that a portion of the brain is to be looked upon as the organ of causation, and such portion is injured or destroyed, there is no reason why the remaining sound portion of brain should not take on, at least to a certain extent, in addition to its own, the functions of that part which has been injured. If, independently of any phrenological views, we admit the brain to be the organ of thought, there is no reason why we should not admit that the loss of intellectual power produced by lesion of one part may not be supplied by an increase of activity in the remaining portions. It is only by a supposition of this kind that we can account for the preservation of the integrity of mind in many cases of disease of the brain. If we admit the phrenological doctrines, we can suppose that when one organ is injured, another may take on an additional function, and in this way preserve the integrity of the intellect; so that, whether we reason from phrenology or not, the continuance of soundness of mind, in cases of injury of the brain, can be understood when you come to contrast it with other analagous pathological facts. I again repeat, that it is not more extraordinary that, in case of local injury of the brain, the sound parts should take on a supplemental action, than that bile should be eliminated by the salivary glands, skin, and kidneys, or that the principles of urine should be discharged from almost every part of the system, or that a vicarious discharge from the roots of the hair should supply the place of the uterine secretion.

On this subject one point should be always borne in mind, viz., that we may be wrong in saying that a patient is *quite sane* while he is still an invalid and in bed. Unless we can show that after his recovery, and in his various intercourse with the world, he preserves his original intelligence, it would be wrong to assert that there has been absolutely no lesion of intellect consequent on the affection of the brain. While lying at ease in bed, and unaffected by any moral stimuli, he may seem to possess a sound condition of mind, he may put out his tongue or stretch forth his hand when requested; he may give an accurate account of his symptoms, and answer all

ordinary medical interrogatories with precision. But you are not from this to conclude that he is perfectly sane. Many persons under such circumstances have died in bed, and appeared to preserve their intellect to the last, but in such cases the test of sanity, *intercourse with the world*, could not be fairly applied, and hence I think that there are not sufficient grounds to pronounce a decided opinion as to the real condition of the intellect in such cases.

Before I quit this part of the subject, I wish to make a few remarks on the doctrines of phrenology. There can be no doubt that the principles of phrenology are founded on truth, and of course highly deserving of your attention, as likely at some future period, when properly cultivated, to exercise a great influence over medical practice. The great error of the phrenologists of the present day consists in throwing overboard the results of pathological anatomy. If a pathological fact is brought forward, as appearing to bear against the validity of their opinions, they immediately exclaim, "we don't recognise any fact or principle drawn from disease: our science has to do with the healthy and not the morbid condition of the brain." Now, this is altogether absurd. Phrenology, if true, is nothing but the physiology of the brain, and pathology is nothing but the physiology of disease. Phrenology must be tested by disease as well as by health, and if it does not stand the test of pathology it is wrong. If phrenology be a science founded on truth, if it is a true physiology of the brain, or of that portion of it connected with mental phenomena, one of two results should obtain,—either that it should be confirmed by pathology, or that the difficulties, which pathology presents, should be explicable in a manner consistent with the science. The phrenologists, in my mind, are doing a direct injury to the cause of their science, by their unnecessary and ill-timed hostility to pathology. It is idle to say, as they do, that theirs is the science of health, and that it is unfair to apply to it the test of disease. From pathology is drawn a host of facts, from which the doctrines they profess derive their principal support. The mere phrenologist, who understands not and despises pathology, is nothing better than a charlatan, and professes a science which he does not comprehend. If he would recollect that the brain in a state of health is most, and in a state of disease least, adapted to the purposes of thought, he would see that this is one of the strongest arguments in favour of his doctrine, that the brain is the organ of mind. The more healthy it is, the fitter is it to discharge the functions of intellect, and vice versa, yet phrenologists are so absurd as to think that pathology has nothing to do with their science.

But besides confirming the doctrine that the brain is the organ of thought, there are innumerable facts drawn from pathology, which have a tendency to prove that particular parts

of the brain are the organs of peculiar phenomena. We see an injury of one part of the brain, accompanied by a train of symptoms indicating some peculiar lesion of mind; we see an affection of another part attended by a different class of phenomena. Here pathology, the science which phrenologists reject and despise, goes to establish the ground-work of their doctrines, that the brain consists of a congeries of parts, having each a separate and distinct function. We find, for instance, that disease of one portion of the brain affects the intellect, of another, the generative organs, of a third, the muscular system. What does this prove but that the brain is not a simple organ, but composed of a congeries of parts, each of which governs a different part of the system or ministers to a peculiar purpose. Now, what is this but what the phrenologists themselves wish to prove?

Further, the professors of phrenology have placed all their organs on the surface of the brain, and for this they have been loudly censured. Phrenology, it is urged, knows, or professes to know, nothing about the central parts of the brain, which must be equally important with the superficial, and have confined their investigations to the surface alone. Now it is a curious fact, that the pathology, which they deny, in this instance furnishes the best reply to this objection. I mentioned at my last lecture, that if we examine the symptom of delirium, we find that it characterises the inflammation of the periphery, and is commonly wanting in that of the deep-seated portions. In other words, mental alienation is the characteristic of the disease of that portion of the brain, where the phrenologists have placed the intellectual organs. Here is a strong fact in favour of the doctrines of phrenology, derived from that science, which the mere phrenologist throws overboard and despises. Again, according to the researches of some celebrated French pathologists, there are a number of facts to show that there is a remarkable difference between the symptoms of arachnitis of the convexity and of the base of the brain. This conclusion, which after a most careful series of investigations was adopted by them, is borne out by the results of my experience, and appears to me to be established on the basis of truth. They have discovered that arachnitis of the convexity of the brain is a disease characterised by prominent and violent symptoms, early and marked delirium, intense pain, watchfulness, and irritability. We have first delirium, pain, and sleeplessness, and then coma. But in arachnitis of the base of the brain, the symptoms are of a more latent and insidious character, there is some pain, and the coma is profound, but there is often no delirium. What an important fact for the supporters of phrenology is this, and how strikingly does it prove their absurdity in rejecting the lights derived from pathology! Here we find the remarkable fact, that inflammation of the arachnoid, investing the base of

the brain to which the phrenologists attach comparatively no importance, is commonly unattended with any lesion of the intellectual powers, while the same inflammation on the convexity is almost constantly accompanied by symptoms of distinct mental alienation.

It is objected to the phrenologists that they know little or nothing of the central parts of the brain, that though these parts may be fairly considered to be of as much importance as any others, still they do not admit them to be organs of intellect. Now, what does pathology teach on this subject? It shows that we may have most extensive local disease of the central parts of the brain, that we may have inflammation, suppuration, abscess, and apoplexy, without the slightest trace of delirium. Indeed there can be no doubt that the central portions of the brain have functions very different from those on the surface. They appear more connected with another function of animal life, muscular motion and sensation. Then, let us examine the phenomena of old age. Every one is familiar with the fact that when a man arrives at an extreme age, he generally experiences a marked decay of intellectual power, and falls into a state of second childhood. Does pathology throw any light upon this circumstance? It does. From a series of ingenious and accurate investigations conducted by two continental pathologists, Cauzeviell and Desmoulins, it has been found that a kind of atrophy of the brain takes place in very old persons. According to the researches of Desmoulins it appears, that, in persons who have passed the age of seventy, the specific gravity of the brain becomes from a twentieth to a fifteenth less than that of the adult. It has also been proved that this atrophy of the brain is connected with old age, and not, as it might be thought, with general emaciation of the body; for in cases of chronic emaciation from disease in adults, the brain is the last part which is found to atrophy, and it has been suggested that this may explain the continuance of mental powers, during the ravages of chronic disease; and also the nervous irritability of patients after acute diseases, in which emaciation has taken place.

I might bring forward many other facts to show that phrenology is indebted to pathology for some of the strongest arguments in its favour, and I think that those phrenologists who neglect its study, or deny its applicability, are doing a serious injury to the doctrines they seek to establish. The misfortune is that very few medical men have turned their attention to the subject, and that with few exceptions, its supporters and teachers have been persons possessing scarcely any physiological, and no pathological knowledge. Phrenology will never be established as a science until it gets into the hands of scientific medical men, who, to a profound knowledge of physiology, have added all the light derived from pathological research. To give you an instance

of the mode of reasoning of the non-medical phrenologists. In their drawing-room exhibitions, they appeal with triumph to the different forms of the skull in the carnivorous and graminivorous animals with respect to the development of destructiveness; and all are horrified at the bump on the tiger's skull. But as Sir H. Davy well observes, this very protuberance is a part of the general apparatus of the jaw, which requires a more powerful insertion for its muscles in all beasts of prey. Phrenology, as generally taught, may answer well for the class of dilettantis and blue stockings, or for the purposes of humbug and flattery, but its parent was anatomy, its nurse physiology, and its perfection must be sought for in medicine. The mass of inconsequential reasoning, of special pleading, and of "*false facts*," with which its professors had encumbered it, must be swept away, and we shall then, I have no doubt, recognise it as the greatest discovery in the science of the moral and physical nature of man that has ever been made. I feel happy, however, in thinking that of late the science has been taken up on its true grounds, in Paris, London, and Dublin. Vimont's splendid work on Comparative Phrenology will form an era in the science. In London Dr. Elliotson has directed the energies of his powerful mind to the subject, and in Dublin we have a Phrenological Society, of which Dr. Marsh is the president, and my colleague, Dr. Evanson, the secretary, and under such auspices much is to be expected.

Having drawn your attention to the ordinary symptoms of local encephalitis, our next inquiry is how far we can diagnose the actual seat of disease from phenomena observed during the life of the patient. Do not suppose for a moment that this part of the subject is undeserving of your attention, in the strongest sense of the word. Recollect that the more accurate and extensive is diagnosis, the more certain and available is the practice of medicine. On this subject matters are not altered to the same extent as in the cases of chest, or abdominal diseases. In our knowledge of the two latter we have made vast strides within the last few years, but in cerebral affections, though much has been effected, much still remains to be done; and it is not improbable that some of the opinions on this subject still promulgated in schools require correction. If we examine the various cases of cerebral disease on record, we find that in some the paralysis was complete, and that sensation and muscular motion became as it were annihilated. In other cases the muscular system alone appeared to suffer, while in a third class we find that sensibility is destroyed, while the power of motion remains intact. Again, in some we have complete hemiplegia, in others the paralysis is but partial; in some the affection is slight and transient, in others it is incurable and permanent. The result of all this would appear to imply that there are

different states and seats of cerebral disease, producing different modifications of nervous phenomena. It has been taught that a paralysis of the organs of speech, points out a lesion of the anterior lobes of the brain, and there are many cases on record in support of this opinion. Here is a pathological statement strongly in favour of the doctrines of phrenology. But on the other hand it must be confessed that there are numerous cases on record of lesion of the powers of speech, independent of any affection of the anterior lobe; and hence as far as the diagnosis of lesion of the anterior lobe, derived from loss of speech is concerned, we cannot make up our minds. You are aware that the phrenologists place the organ of language in the anterior inferior part of the brain. Now when an affection of this portion of the brain is found to coincide with the loss of speech, it is all very well, but the difficulty is to account for those cases of loss of speech, in which there is no appreciable lesion of the substance of the anterior lobe. In investigation on this point, however, you must bear the following distinction carefully in mind. The organ of language of the phrenologists is not properly the organ of the *power of speech*, but that by which, as it were, thought is converted into language. A man, from paralysis of his tongue, might be incapable of speaking, and such a case, existing without lesion of the anterior lobes, might be most unfairly quoted against the phrenologists. Again paralysis of the upper extremities has been connected with disease of the optic thalami and posterior lobes of the brain. It is the opinion of Bouillaud, Serres, and others, that the optic thalami regulate the motions of the upper extremities, and it is a fact, that in many instances of paralysis of the upper extremities, disease has been found in these parts. We might term the following a synthetic case illustrative of the doctrine:—"A soldier was wounded in the right shoulder with a lance, in consequence of which he got an aneurism of the axillary artery, for which an operation was performed. At the moment the ligature was tightened he experienced exquisite pain in the situation of the ligature, which extended to the brachial plexus; this continued until the next day and then ceased. On the fourth or fifth day the pain returned with increased violence, and continued until the seventh day, when it became intolerable. He was bled, but without any good effect, he then became comatose; his head was drawn backwards; he had alternations of stupor and excitement, and soon after expired. On dissection the ligature was found to embrace some of the principal branches of the brachial plexus, and there was an abscess in the posterior lobe of the brain, extending to the optic thalamus. Here we have a case of injury of the upper extremity, and that portion of the brain, which is supposed to govern it, was found in a state of manifest disease. Serres gives also the details of some experiments in support

of this opinion. On removing the posterior part of the right hemisphere of the brain in a dog, he found that the left anterior extremity became paralytic; he prolonged his incisions into the corresponding portion of the opposite hemisphere, and found that the right extremity became paralysed. In another dog he plunged a bistoury into the posterior part of the right lobe, and found that the left anterior extremity became affected with convulsive motions. He then introduced into the wound a few drops of nitric acid, so as to produce inflammation of that portion of the brain, and observed that the convulsions of the left fore-foot became more violent; in fact, that the animal had all the symptoms of a local inflammation of the brain, namely convulsions, rigidity, and then paralysis. Rolando has performed a series of experiments with the same view, and his conclusions are exactly those of Serres. So that if we connect the results of these experiments with some facts drawn from pathology, we might conclude that the optic thalami, and posterior lobes of the brain, have a very important share in regulating the muscular motions of the upper extremity. I may here state, that, in this city, a case of a female occurred, who got an attack of severe pain in the left hand and fingers, which became afterwards contracted, and she had, in addition to this, alternate flexions and extensions of the fore-arm, *followed by resolution and paralysis*. On dissection there was an abscess found in the right optic thalamus; the rest of the brain was healthy.

With respect to those cases, in which there is paralysis of one of the lower extremities, it has been taught that it arises from disease of the corpus striatum. On the anterior lobe the following case is given by Serres. "A woman, 40 years of age, had an attack of apoplexy, from which she recovered with the left leg in a state of complete paralysis, and the left arm admitting of a slight degree of motion. Here was a case of lesion of both the upper and lower extremity of the same side, but in the former the paralysis was partial, in the latter complete. On dissection it was found that two circumscribed abscesses existed in the substance of the right hemisphere, the larger situated in the corpus striatum, the smaller in the optic thalamus. Another case is given of a patient who got paralysis of the side; the muscular power of the arm being completely destroyed, while the leg retained a considerable degree of motion. In this case the corpus striatum was but slightly affected, while nearly the whole substance of the optic thalamus was destroyed. I have also to remark, that Serres performed similar experiments on the corpus striatum in dogs, and came to the conclusion, that it governs the motions of the lower extremities. The structure, extent, and special action of the corpus striatum and optic thalamus, are said to afford some explanation, why, in ordinary cases of paralysis, the arm is more often affected than the leg, and does not recover so soon. The fact of the pro-

elongations of the optic thalami being much more complicated and extensive than those of the corpora striata, is thought to explain their greater liability to disease.

There are, however, not unfrequent exceptions to this law, and it is not uncommon to meet with cases which militate against the doctrines laid down by Serres and other pathologists, particularly so far as regards the connexion between the corpora striata and the government of the lower extremities, so that I would have you look upon it as a point *by no means* fully established. The latest observations on this subject are by Andral, who brings forward many facts opposed to the opinions of Serres, Foville, &c. &c. Out of seventy-five cases of accurately circumscribed disease of the brain, the disease being hæmorrhagic or otherwise, he found that in forty, where the paralysis existed in both extremities of one side, there were twenty in which nothing was injured but the anterior lobe, or the corpus striatum; while in nineteen the lesion existed in the posterior lobe, or the optic thalamus. In these seventy-five cases, also, were twenty-three in which one arm was paralysed. In these, eleven presented the disease in the anterior lobe, or in the corpus striatum; ten in the optic thalamus, or posterior lobe; and two in the middle lobe. Finally, out of these cases were twelve of paralysis of one arm; ten of these presented disease in the corpus striatum, or anterior lobe, and two only with disease in the optic thalamus, or in the posterior lobe.

These facts, gentlemen, prove how uncertain the matter is yet. It would appear that when a simultaneous and equal injury of both corpora striata and optic thalami exists, it would be natural to expect complete paralysis of one side, and I believe there are some cases on record in support of this opinion. But when you have paralysis affecting both sides of the body, you are not to suppose that there is necessarily an affection of the corpora striata and optic thalami, for such symptoms, in the majority of cases, are found to depend upon either an intense congestion of the brain, or a large serous, or sanguineous effusion. The same phenomena are produced by the pressure exercised by the diseased on the sound hemisphere, in a case of local encephalitis, or by disease affecting the upper part of the spinal cord.

With respect to disease of the cerebellum, the only means of determining its affections consists in first considering the seat of the pain, if any, and in the next place the effect on the genital system. There are a great number of cases detailed in various treatises in proof of the close connexion between the cerebellum and the genital function. I shall relate a few of these. A man, aged thirty-two, got an attack of apoplexy, followed by violent erection of the penis, which continued until death: here we have a case of apoplexy accompanied by priapism. On dissection the

whole of the cerebrum was found healthy; but there was an apoplectic effusion in the middle lobe of the cerebellum. Another case is given of a man, aged fifty-five, who died of apoplexy in a brothel, and who, after the attack, had violent priapism.

On dissection the substance of the cerebellum was found to be extensively destroyed, and there was an apoplectic effusion in the fourth ventricle. There is a remarkable case on record of a prostitute, in whom the clitoris was extirpated, as it was considered that it was the irritation of that organ which brought on a pernicious habit, by which her health was greatly impaired; and it was conceived that as soon as the supposed source of excitability was got rid of, she would give up her vicious propensity, and be restored to health. But in this instance it is probable that the effect was taken for the cause; for on her death, which took place some time after, the cerebellum was found to contain a number of chronic abscesses. Serres gives the case of a woman who died of an apoplectic effusion into the cerebellum. During the fit she had hæmorrhage from the uterus; and, on examining that organ after death, a large clot of blood was found within its cavity, and the broad ligaments, ovaries, and, in fact, every part of the generative apparatus were in a state of high vascularity. Yet this female was seventy years of age, and her menses had ceased at the usual period. There is a most important case bearing on this point on record. A gentleman, who was subject to constant and distressing nocturnal emissions, consulted his physicians, who, considering them to be the result of debility, prescribed various tonic and stimulant remedies. He used various preparations of iron, bark, camphor, opium, hyoscyamus, nitric acid, and many other things of a similar kind, but without advantage. From the fact of the failure of all these remedies, and the circumstance of his having complained of an occasional sense of uneasiness in the back of the head, his physician was led to think that his symptoms might have some connexion with an excited condition of the cerebellum; and, under this impression, had the back of the head shaved, leeches, and covered with a quantity of pounded ice. *From this time his symptoms began to decline rapidly, and in a fortnight he was quite free from complaint.* Now, this case, taken singly, would prove very little; but when we view it in connexion with the number of cases in which disease of the cerebellum has been known to be followed by excitement of the genital organs, it becomes of considerable importance. I have now seen two cases in which this connexion was observed. In the case of a young man who was brought into the Meath Hospital some time ago with paraplegia, it was observed that the penis was in a state of constant erection, and there were continual seminal emissions. On dissection an effusion of blood was found in the cere-

bellum, and another in the hemisphere opposite the paralysed side. There was another case of a patient who was attacked with apoplexy and paralysis of one side, but with the unparalysed hand he continued to attempt the act of masturbation, so that it was necessary to tie down his hand. On dissection there were several effusions in the substance of the cerebellum. All these facts strongly go to prove the connexion which subsists between the cerebellum and the generative function; and I think it would not be unsafe to make the diagnosis of disease of that organ in cases of cerebral disease, where the genital system was much excited.

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c., &c.

At the Westminster Hospital.

LECTURE XVI.

On the Diseases of the Prostatic Part of the Urethra.

GENTLEMEN,—The prostatic part of the urethra is subject to irritation and inflammation in young persons, occasionally ending in abscess of the prostate gland; but these complaints are rarely idiopathic, and occur for the most part from the extension or metastasis of disease from the anterior portion of the urethra, and are generally curable. The diseases, on the contrary, which afflict elderly persons, usually originate in the gland, with little reference to the urethra generally, are by no means so well understood, and rarely admit of a cure being accomplished, although the symptoms and sufferings of the patient may be greatly relieved.

In young persons, the membrane lining the prostatic part of the urethra may be alone affected as a consequence of gonorrhœa, in which case it will be either from acute or chronic inflammation, and in both usually extending, in a greater or less degree, to the orifice, or even into the neck of the bladder itself. When the inflammation is acute, the patient is sensible of a great alteration in the symptoms; instead of a considerable discharge with little pain, and that little confined to the anterior part of the urethra, the discharge nearly ceases, or is greatly diminished in quantity; the pain is now referred to the perineum, and, as the patient expresses it, to the neck of the bladder. He complains of pain above the pubes, which is more or less permanent; of a constant uneasiness deep in the urinary passage, which is frequently augmented to an irresistible desire to make water, and which gives him great pain from the moment it passes from the bladder. The tenderness in the perineum is considerable, accompanied by a disagreeable sense of fulness, which prevents the patient

sitting comfortably unless on a soft cushion; and there is an uneasiness and weight about the hips and left thigh, which causes great lassitude, and increases the anxiety of the patient, who feels otherwise ill, and has the usual symptoms of general irritation. The inflammation has, in this case, been suddenly extended to the prostatic part of the urethra, and should be subdued by general as well as local antiphlogistic means. If the person is young and plethoric, blood should be drawn from the arm: twelve or fourteen ounces taken away in this manner often give greater relief than anything else; and if followed up by a hot bath at 100°, in which the patient should be kept until he nearly faints, will often alone effect a cure. If the attack is severe, cupping on the perineum and on the sacrum should be resorted to; and leeches should be applied above the pubes, more particularly when pain is experienced in that situation. In fact, active depletion, and more particularly local depletion, always does the greatest good in these acute attacks of inflammation in young persons, whilst, in elderly individuals, when the symptoms are nearly as urgent, although the inflammation is not perhaps so acute, and more confined to the bladder, its efficacy is sometimes doubtful, the relief obtained being evanescent, the debility permanent. In these different cases (and they are not rare) I believe the difference to be this: in the young person, the inflammatory action is not accompanied, or has not been preceded, by any change of structure, whilst in the elderly man, a change of structure has been slowly going on, upon which the inflammation has supervened. If the inflammation is temporarily arrested by the depletion, it almost immediately returns, as the cause which induced it continues to exist, and assists in its reproduction.

Opium, and particularly morphia, is a most valuable remedy after depletion: it allays irritation, and assists materially in the removal of the inflammation. The various preparations of it may be given internally, or they may be used per rectum, in the proportions I usually recommend, of twice the quantity ordered for a pill or draught, and which is to be injected in a small quantity of starch or gruel, not exceeding two, or at most three, ounces. It must be repeated from time to time, so as to keep the irritation under command; and its constipating effects should be obviated by an occasional enema of hot water administered previously, and by small doses of castor oil, or some other gentle aperient medicine; for drastic purgatives are not useful in acute inflammation of the prostate, although active purgation is advantageous in chronic disease of this organ. The recumbent position should be observed, with the hips rather raised than otherwise. In young persons it will rarely be necessary to introduce a catheter, unless supuration is about to take place, and there is a retention of urine, when it should always,

under such circumstances, be a very small and very flexible instrument, which is to be withdrawn immediately. A catheter is frequently allowed to remain in the bladder, when the inflammation is in a chronic state, with advantage. It is always injurious when the inflammation is acute; but is frequently useful when there is irritation without inflammation, if that peculiar state can be duly ascertained. The hot bath, used generally as well as locally, gives considerable relief; and the constitutional derangement, or the febrile symptoms, must be attended to in the usual manner; all food being withheld, and the drinks allowed being of the most bland and diluent nature.

When, from the continuance of the disease, the occurrence of rigors, and the increase of the febrile symptoms, the augmented sense of fulness and tension in the perineum, and the greater difficulty of making water, the formation of matter may be presumed; an examination per rectum will often give considerable information, in addition to the swelling which may be perceived externally. It is very desirable the abscess should neither break into the rectum nor into the urethra, nor that the matter should insinuate itself behind the bladder, nor indeed go anywhere except to the surface. The same precautions should be observed, and the same practice followed, as in abscess by the side of the rectum, by making an early puncture. If matter should not follow on the first day, it generally will on the second; and the straight sharp-pointed bistoury should be used for this purpose, and pressed on, from the perineum through its deep fascia, by the side of the urethra, and above the rectum, until the surgeon is assured that it has penetrated the swelling; the flow of matter from which will prove the fact, and the slight bleeding which will ensue must, under such circumstances, do good. An abscess which is opened in this way, or which opens of itself in this manner, usually heals with little difficulty. If it opens into the rectum it is always a serious matter, and it is by no means readily cured when it bursts into the urethra. If it passes behind the bladder death is often the result, after a very prolonged illness, of which I have seen some very unhappy examples; but these, as Sir Charles Bell has observed, generally occur in persons of a scrofulous habit.

Chronic abscess of the prostate, or rather an abscess the result of a lower or more chronic inflammation, is a much more frequent disease, occurring generally from forty to fifty, and even to near sixty years of age. It is usually the consequence of stricture, but is not always so; and is generally complicated with inflammation of the mucous membrane of the bladder, and ultimately with disease of the kidney, by which the patient is destroyed when the disease proves incurable.

One of my earliest friends was thirty years ago attacked with uneasiness in the back part of the urethra, a great desire to make water,

and pain on passing it, without any discharge, but with a sense of fulness in the perineum, of weight in the hips and loins, and the uneasiness was increased on evacuating the bowels. I attributed this to the irritation arising from sitting continually with a lady to whom he was much attached, and whom, for the best of all possible reasons, he could not marry. This lasted three weeks, before it was removed by a strict antiphlogistic plan of treatment. He had another attack, at Lisbon, in 1809, which yielded in a similar manner; and he was quite aware of the difference between this disease and a common gonorrhœa, a disease he had contracted in the interval two or three times, and had been cured in the usual way, the last by commencing immediately with small doses of copaiba, and increasing the quantity until the cure was completed, after the manner that has been since recommended as new. In 1817 he had another attack, which was more obstinate, but ultimately yielded to a similar treatment, with the addition of a mild course of mercury. After this he married, and remained well for several years, but unhappily became a widower, and some months afterwards had a return of his complaint without any very evident cause. All the usual remedies now failed, and his disease gradually increased. During three years, he consulted all the most eminent surgeons in London, and at last died, completely exhausted, under the care of Dr. Prout. On opening the body, I found the prostate almost an empty sac, having been the seat of several abscesses communicating with the urethra. The internal surface of the bladder was in a state of chronic inflammation, but without ulceration, although, from the pain at the extremity of the penis, and the amazing quantity of discharge, almost apparently of a purulent nature mixed with the urine, considerable ulceration was expected. The ureters were much enlarged, and the kidneys diseased, that of the left side particularly being enlarged, softened, and on cutting into it, found nearly an empty lobulated bag.

When a stricture has been of long standing, and frequently impassable, accompanied by great straining, and occasionally even by retention of urine for hours, abscess in the prostate is of common occurrence, and the formation of matter is often accompanied by such well-marked paroxysms of fever, as to resemble and to be taken for ague. In some instances the fits became even regular for a time, and again irregular. I place before you several preparations showing this fact. In this particular one, in which the prostate seems to hang in rags, abscesses extended up between it and the back of the bladder and rectum, and would have killed the patient if he had not been cut off by ulceration of the gall-bladder, through the irritation of a large gall-stone. The disease in this case was originally stricture, and the

quantity of matter discharged at intervals, together with the particular uneasiness and tenderness of the prostate on examination per rectum, marked the disease, with which the bladder also sympathised.

The following case of a physician, a friend of mine, who has been under my care during the whole of his illness, drawn up by himself, is an instance I have always told him of abscess of the prostate, and, if I outlive him, I am to ascertain the fact.

"Feb. 15, 1830.—Nearly seven months ago, while riding on horseback in the country, I was surprised one morning to find that I had frequent calls to make water without any obvious cause, and that the contents of the bladder were expelled with force, as if I had been taking a strong diuretic. The urine, too, was of a wheyish colour, unlike the thin colourless transparent fluid I had been in the habit of passing in the forenoon. These symptoms continued upon me, and were attended in the course of a few days with ardor urinæ and pain in expelling the last drops, like a wringing tenesmus of the bladder, whenever, more especially, I mistook the call, and went to make water with only a small quantity in the bladder. During my whole life I have had a highly sensitive irritable urethra, and having, about ten days previously, been attempting to take oil of turpentine for ophthalmic inflammation, which I was quickly obliged to discontinue on account of the ardor urinæ that it induced, I attributed the symptoms to some remaining effects of that stimulus, and attempted to subdue them by warm-baths, camphor in large doses, hyoscyamus, &c., but without success. As I had once in my life, thirty years ago, suffered greatly from stricture, which was finally overcome by the perseverance of Sir E. Home with the caustic bougie, my friend Mr. Guthrie had little doubt of my symptoms being caused by some return of that affection, but a small sized instrument passed readily, and the stream of urine has never been diminished or abstracted. Ever since that time till very lately, I have been a miserable invalid, suffering at times the greatest distress from irritation, apparently in the urethra, and the spasmodic wringing tenesmus (bearing down) of the bladder above described; and I cannot satisfy myself or believe that any plan of treatment, whether the antiphlogistic, the antispasmodic, the alkaline, the alterative, or the stimulant (with copaiba, &c.), after the fairest trials, were ever of the smallest service to me. No matter what plan I followed, or however rigorously pursued, the quantum of distress was just the same, and the relapses or accessions and paroxysms, without any discoverable or even to be imagined cause, just as frequent.

For several months an instrument, on passing into the bladder, which has often been done to ascertain the state of the passage, and to sound for stone, always caused the greatest

pain when it entered into and passed through the prostate portion of the urethra, and Mr. Charles Bell, on examining the prostate gland, thought he could distinguish a small pouch, or abscess there, as far back as three months ago. Latterly, however, at a subsequent examination, that gland appeared almost healthy and natural, yet the symptoms of distress and irritation were then greatly on the increase. The urine, from the day of the first discovery till very lately, had not once been natural; it was then of a wheyish colour; it became afterwards either albuminous or muco-purulent, frequently in a very high degree. The best appearance was like a mixture of honey and water, or rather of honey adulterated with wheaten flour to make it white; at other times, and then I always suffered greatly, it was actually purulent, like the sanious contents of an ill-conditioned abscess; at others, again, the last drops only were thick and white as cream, but it never was woolly or soapy. My state was that of a patient suffering more or less irritation at all times in the urinary passages, and never altogether free from tenesmus of the bladder, with an accession or relapse into great suffering and distress, about every week or ten days, when there was always a great discharge of muco-purulent sediment. After these I generally obtained comparative ease, but I possessed no power over their recurrence, which, for several months, actually seemed to be regularly periodical, rather than to depend upon any causes of exposure to weather or excitement from exercise or fatigue, for the worst of them happened while nursing myself with the greatest care, under the most approved modes of treatment, and what I cannot account for, when I have been reposing in bed after the middle of the night, or earlier in the morning when indulging on my sofa. Even now, when my symptoms are so much mitigated, if there be the smallest tendency to relapse or irritation, it is between the hours of three and six in the morning that I feel the symptoms in frequent calls to make water, with uneasiness in the urethra. At my worst times these were attended with distinct heavy throbbing, so severe that I could have often believed the bladder itself was in a state of suppuration. Such was my condition when, about three weeks ago, under the advice of Mr. C. Bell and Mr. Guthrie, I undertook to inject the bladder with warm water through an elastic gum catheter, which I had attempted repeatedly before with the silver instrument, but the prostate portion of the urethra would not bear the application. It gave immediate ease, and by perseverance with the same once, sometimes twice, in the day, the urine, in the course of a few days, actually became healthy, the bladder could retain, without pain, twelve, thirteen, or fourteen ounces of urine, and I became freed as nearly as possible from the symptoms and feelings of disease. The change was so rapid and extraordinary, so much beyond my expectations, and the failure of every other plan

of treatment, however skilfully conceived, had been so remarkable, that I could scarcely bring myself to believe or understand how the simple injection of warm water could have wrought such a miracle. Its truth, however, I consider to be established from the fact, that whenever I perceive the smallest tendency to relapse, which, in the sensitive state of my urinary organs, I am sure to feel on exposure to fatigue, the inclemency of the weather, neglect of my bowels, or departure from the strictest regimen in my diet, the warm water then is my sheet anchor of safety, giving the same relief as it did on the first application.

"June 8th, 1834.—My last report was dated February, 1830, now more than four years ago, when I flattered myself I had almost obtained a cure by injecting the bladder with warm water, but this relief did not last and I ultimately found this remedy as inefficacious as all the others I had tried. The Pareira brava, buchu, uva ursi, the Brixton parsley, galls, &c. were all brought into play in their turn, and all seemed to give some relief at first, but in all the relief was transitory and fallacious; the best of them seemed to be of the pepper tribe, such as the cubebs and the capsicum, but these too have long been discontinued as useless, and given place to the steady use of opium, through which I have derived greater comfort, and been enabled to take exercise and enjoy life in a degree I never expected in this world. My dose is now, and has been for months past, a steady one of one grain morning and evening, and when attacked with irritation I repeat it to as far as three or four times that amount if necessary, almost always with complete relief. I am not cured, and at my age (61) I never expect to be, but when I compare my situation now to what it was several years ago, I am most grateful for the improvement. The urine now is seldom mucopurulent; through the day it often, indeed generally, exhibits, more or less, flakes of albumen floating throughout the mass, and cannot otherwise in any way be called foul or unhealthy, except in the morning, when it is uniformly more loaded with mucous deposits, and less healthy in appearance than at any other time. It is then, too, just before getting up on first awakening that I have always more irritation and uneasiness than at any other time of the day, but at present I can throughout the day retain without distress ten, twelve, and fourteen ounces of urine, and I am seldom disturbed more than once in the night to make water. I recollect nothing else worth mentioning, except that when I pass a catheter I feel uniformly excessive tenderness and pain as soon as the instrument enters the membranous portion of the urethra, and that there is generally, more especially in the morning, a slight discharge of ropy mucus at the orifice of the urethra, such as is perceived at the termination of the cure of gonorrhoea. For the encouragement of others, similarly distressed, I ought also to add, that in all the former part

of my life I considered opium to be a drug so inimical to my constitution, as to be inadmissible under any shape. It is now my sheet-anchor, and has proved as useful to my general health, as it has been beneficial to my local disease." In the beginning of 1834 the urethra was scarcely pervious to a No. 3 catheter, which I passed with difficulty, in consequence of the return of the old stricture, but which had been dilated. This gentleman is now in good health and good condition, capable of enjoying himself at table with his friends, and will, I hope, long continue to do so.

Inflammation, followed by abscess of the prostate, is always accompanied by irritability of the neck of the bladder, and which is frequently propagated to the kidneys. This is best allayed by washing out the bladder with warm water, and by leaving in it a small quantity, combined with from half a grain to a grain of the acetate of morphia. The soundness of the bladder is perhaps best shown by its capability of containing from eight to twelve ounces of urine at a time, but it is exceedingly difficult to discriminate between that irritation of the neck of the bladder which arises from sympathy with disease of the kidney, and that which occurs from disease of the part itself; and it is more difficult at a later period to ascertain which was the primary disease. If there be stricture of the urethra, it should be gently dilated, and the irritation may be removed by the means I have pointed out; but the bougie, or dilating instrument, must not remain or be passed into the prostatic part, unless the patient cannot make his water, or the doing so is accompanied by more pain than the passing of the instrument, which should be the guide for our instruction. Few patients can bear a catheter in the bladder under these circumstances, and the occasional use of it must depend on the feelings of the patient as to the advantages derived from it.

A strumous habit has been supposed to render persons more liable to this complaint, but I have not observed that it does so, and believe that it does not, except in those persons who may suffer from it in early life. In the middle and later periods I do not think scrofula has anything to do with it. When the matter of the abscess has been discharged, change of air, particularly to the sea side, quinine, sarsaparilla, galls, the turpentine and balsams, all in very small doses, so as to be scarcely diuretic, and always to act as it were imperceptibly, often do good; and the patient should preserve as much as possible the horizontal posture, avoiding all unnecessary excitement. The advantages to be derived from the steady use of opium are too clearly shown in the preceding case to be disregarded.

The prostatic part of the urethra and the neck of the bladder are often affected in middle-aged persons, and sometimes in young ones, by mere irritation or low inflammation, which gives rise in both to troublesome symp-

loans. In young persons it is more usually from the sequel of gonorrhœa, in elderly ones it more often arises from the irritation of the urine, which is secreted of an undue and irritating quality, depending on a faulty state of the stomach and bowels.

When it follows a gonorrhœa, or has existed for some time as a sequela of it, the cure is to be accomplished by strict attention to the general health, diet and exercise, and by the use of the bougie. This is to be used only after an interval of three or four days, and should be a very soft one. It gives great pain on passing through the prostatic part of the urethra, and the point of the bougie comes out in all probability tinged with blood and matter. After two or three trials, a little purulent matter only is observable, and by a continuance of its use a cure is generally effected, but the patient is liable to a relapse, unless he is very careful to avoid all exciting causes of disease, and particularly that of intemperance. In some obstinate cases, where other means have failed, I have reaped advantage from the use of mild stimulating and sedative applications to the part affected, through the medium of a hollow bougie, in the manner I have already described.

On the Chronic Enlargement of the Prostate Gland.

This disease is, as far as we know, produced by those changes which take place in the body in its natural progress to decay, being commonly observed to a greater or less extent in all elderly men. It occurs in some at a much earlier period than in others, does not appear to depend on any previous irregularities of life, or scarcely to be influenced by them; and as it does not take place, or has not been observed in the *corpus glabosum* or prostate of the female, which is destitute of a secreting structure, this part may reasonably be supposed to be the texture in which the peculiar change takes place constituting the disease.

It was formerly presumed to be of a scirrhus or malignant nature, from the hardness which occasionally accompanied its formation; but as it has not been observed to communicate an influence of this kind to the neighbouring parts, or to any other analogous textures of the body, which usually suffer from malignant diseases, the idea has been abandoned. The only extension of a similar disease that I have seen has been of an apparently chronic suppuration, of a scrofulous character, of the nearest absorbent glands. I have seen this in only two instances, and the first occurred in an old man in Wardour-street. The prostate was larger than a closed hand, had partaken of a suppurative process of this kind, and the whole pelvis was nearly filled up by a mass of disease of a similar character. In the more common kind of enlargement, the

part is rather soft than hard, yielding a little to the touch, and not elastic or springy, like a spongy tumour. The enlargement is sometimes but trifling, in which case the prostate retains its natural shape, and merely projects a little into and around the orifice of the bladder; but when it is considerable, in very prolonged and neglected cases it is often as large as a full-sized orange. One lateral half is usually much larger than the other, and protrudes into the bladder, giving rise to one or more projections, which cause great distress to the individual, and the nature of which has been, I think, misunderstood. The left side, I am led to believe, undergoes this change more frequently than the right, although no reason can be given why it should be so; and whilst one projection is directly backwards and inwards, it sometimes is seen to form a second immediately behind the orifice of the bladder, and which is frequently mistaken for an enlargement of that part of the gland behind the entrance of the vasa deferentia, and which has been called by Sir E. Home the third lobe. Without denying that a third lobe may exist, and is occasionally diseased and enlarged, constituting a projection of an apparently similar nature, I am of opinion that it is of much more infrequent occurrence than has been supposed, and that some mistake has taken place on this subject. That it is, in fact, not in general the third lobe in a diseased state, but a continuation of the enlargement of the lateral lobe. In the lithograph drawing I show you, a disease of this kind is represented: the third lobe appears to be projecting in a very distinct manner into the bladder immediately behind the orifice of the urethra, and the enlarged left lateral lobe is also seen protruding into it, and forming a second projection by the side of the first. Dissection from behind, however, shows that these two projections are formed by one and the same part, viz.—the left lateral lobe, and that the idea of the smaller pyriform one being formed by the third lobe is an error. I have reason to believe, from several dissections of a similar kind, that the diseased appearance I have shown is more commonly referable to the lateral lobe than to the third lobe.

When the prostate becomes diseased in this manner, it does not descend and bulge in the rectum, as would be the case if the enlargement were equal in all directions; but it rather ascends and projects backwards and inwards, the bladder giving place to the enlargement rather than the rectum. The increase in size upwards of the prostate has also a particular effect upon the urethra, which is augmented in size with it, from its anterior to its posterior wall, and thus becomes a deep and narrow instead of a circular canal. This is shown in the drawing in a very distinct manner, and the size of it, and the quantity of urine which might lodge in it may be estimated, by supposing the two surfaces which

have been slit open to be applied to each other. The letter *f* marks a hole made by the improper use of the catheter in the under part of the membranous part of the urethra. The letter *g* the commencement of another to the right side, and nearer to the prostate. The letter *c* several bruised spots at the neck of the bladder, and to the right side of the smaller projection. These were made by the point of the catheter on its being forcibly carried into the bladder. When the parts were removed from the dead body, and the man died the day after he was admitted into this hospital, the catheter could not be made to pass these spots without considerable force being used at the moment of depressing the handle of the instrument, the point of which went below the projecting central part of the prostate, into the deep sulcus formed below it, and between it and the floor of the urethra. When, on the contrary, the point of the catheter was made to glide along, and to raise the upper surface of the urethra, it slipped into the bladder with tolerable ease. I apprehend and hope that the contemplation of this drawing will not only demonstrate to the student the state of parts in such cases, but impress on his mind the course the catheter should take, or be made to take, in all similar cases in order to enter into the bladder without doing mischief.

When one side of the gland only is materially enlarged, it presses against the opposite side, and carries the urethra with it in a more or less oblique, or tortuous direction, constituting one kind of case in which an elastic gum catheter will pass very easily, without a stilet, when it will not do so with it, and is one in which a silver catheter should never be used. This state is generally discoverable by an examination per rectum.

The effect of these enlargements is first, to lengthen the urethra, so as to render a long catheter necessary; secondly to deepen it, so that it may sometimes contain within the boundary of the prostate a small quantity of urine, which may run through the catheter before it enters the bladder, and thus deceive the inexperienced surgeon. Lastly it deepens the curve of the urethra from the apex of the prostate to the neck of the bladder, which may, and generally will, form another obstacle to the passage of an instrument, whether it be from an enlargement of the third, or the lateral lobe, or from a valvular, membranous, or solid bar drawn across it by the very unequal enlargement of one lobe.

The true chronic enlargement of the prostate is usually slow in its progress, and may attain to great size, and continue for many years without doing much mischief. When even it does become troublesome, it is rarely on account of the disease with which it is affected, but in consequence of that which it induces primarily in the bladder, and secondarily in the urinary organs. It is not a curable although it is frequently a very relievable disease. If attended to in its early stages, its

progress may in general be arrested. It is therefore of the greatest importance that elderly men should pay attention to the manner in which their urine is evacuated, and that they should cease to entertain the opinion, that a slowness and a difficulty in passing their water, is the necessary and irremediable consequence of an advanced period of life.

PROVINCIAL MEDICAL ASSOCIATION.

We wish the medical practitioners in every large city and town in the United Kingdom would establish associations, such as we are about to notice, as these could not fail to be highly beneficial to the profession and the public, by keeping up a friendly feeling among practitioners, ensuring good moral conduct, etiquette, and increasing the respectability of the profession.

At a meeting of medical practitioners held at Bandon, Jonathan Clerke, Esq., M.D., in the chair, it was unanimously resolved,—

- “ That a Medical Association be formed, to be denominated ‘ the Western Medical Society.’ ”
- “ That the Society be composed of the original members, and of all other properly qualified medical and surgical practitioners residing in the county or city of Cork, who shall before the first day of January every year notify to the Secretary their desire to become members of the Association. ”
- “ That after the commencement of the ensuing year, every person desiring admission must be balloted for, his admission or rejection to be decided by a majority of votes. ”
- “ That the qualification for admission be, a degree of doctor or bachelor of medicine from any of the universities, a surgical diploma from any of the colleges, or having served as naval or military medical officer. ”
- “ That the first annual meeting of the Society be held in Bandon in the month of May, the particular day to be notified to the members by the Secretary, and each subsequent meeting be arranged on that occasion. ”
- “ That the management of the Society be confided to a Committee, a Treasurer, and a Secretary, to be chosen triennially. ”

Honorary Members.

Dr. Stokes, Regius Professor of Medicine,
T.C.D.

Dr. Macartney, Professor of Anatomy, T.C.D.

Dr. Barker, Professor of Chemistry, T.C.D.

Dr. Allman, Professor of Botany, T.C.D.

Committee.

Dr. Beamish, Bandon.

Dr. Clerke, Bandon.

Dr. Jago, Kinsale.

Dr. Warren, Kinsale.

Dr. Skottowe, Kinsale.

Dr. Donovan, Union Hall.

Dr. Cleburne, Ovens.

Dr. Nugent, Cork.

Dr. Bennett, Cork.

Treasurer.

Dr. Corbett, Innishannon.

Secretary.

Dr. Wood, Ballinspittle.

- " That the senior members shall preside in rotation; seniority to be calculated from the date of degree or diploma.
- " That at each meeting the members present be invited to propose some subject of conversation or discussion for the following day; the selection to be made by the President.
- " That interesting communications from professional gentlemen, not members of the Association, with which the Society may be favoured through its Secretary, may also be proposed as subjects of disquisition.
- " That all persons proposed as *honorary members* must be *unanimously* admitted.
- " That the annual subscription be 1*l.*, to be paid in advance.
- " The objects contemplated by the original members of the Association are a more general personal acquaintance and intimacy amongst the members of the profession than at present exists, and perhaps the diffusion of a more kindly feeling; the improvement which invariably results from the association and frequent intercourse of professional men; and the weight with which, as an Association, they may prefer any application for professional objects to the legislature."

Signed by order, and in behalf of the meeting,

J. CLERKE, *Chairman.*

S. WOOD, *Secretary.*

*Foreign Medicine.***HÔPITAL DES ENFANS MALADES.**

A General Review of the Clinical Lectures, delivered by M. BAUDELOQUE during the three months of January February, and March, of the present year.

(Continued from page 631.)

Phthisis Pulmonalis — Pneumo-Thorax — Death Four Months after the Attack — Tubercular Excavations of the Left Lung — Perforation of the Superior Lobe closed by a Semi-Cartilaginous False Membrane — Tubercular Peritonitis.

ADOLPHE DEBROGES, eight years of age, of scrofulous constitution, has had successively whooping-cough and measles, and has been much given to masturbation. Since the attack of measles he has complained of frequent cough, constipation alternating with diarrhoea, irregular febrile accessions, vomiting, and pain in the belly, progressive emaciation, and loss of strength. Within the last three days a sudden attack of acute pain in the left side of the chest, accompanied with much oppression. Admitted, the first of December, with the following symptoms:—intense dyspnoea; acute pain in the left side of the chest, increased by percussion; tympanitic sonorousness; absence of respiratory murmur, right side less resonant than the left; cough frequent, and dry; voice feeble; abdomen tumefied; pulse small, 120; skin dry; marasmus. (Marsh-mallow and syrup of gum; white looch, milk, and broth were prescribed.)

Diagnosis.—Phthisis pulmonalis, with tubercular excavation and perforation of the left lung, followed by pneumo-thorax.

On the 12th the fever became suddenly more intense, with agitation, delirium, and vomiting. Twenty-four hours after, a scarlatine eruption, affecting principally the skin of the trunk, running through its regular stages, and terminating in a few days by desquamation.

22nd. Countenance natural; pulse small, regular; cough slight; evident pectoriloquy under the left scapula; appetite voracious; diarrhoea; occasional vomiting; nocturnal sweatings. (White decoction, *decoction blanche*, opiate injections.)

Feb. 4th. Dulness of the left side; crepitous rattle under the clavicle of the same side, cavernous respiration under the left scapula; pectoriloquy with gurgling sound. Fever continues, with nocturnal exacerbations and sweatings; last stage of marasmus.

March 30th. The patient was seized in the middle of the night with acute pain in the abdomen, which was found the next day to be distended and tympanitic. Vomiting took place, followed by convulsive motions and death.

Autopsy thirty hours after Death.—Neck and Chest.—Tubercles in the sub-maxillary ganglia, the mucous membrane of the larynx and trachea pale and discoloured, but not ulcerated; all the mediastinal ganglia transformed into tubercular masses; pleura of the left side adherent; superior lobe of the corresponding lung containing two caverns of moderate size, one at its apex, the other at its base; the lining false membrane of a fibro-cellular texture, the posterior surface of the lobe covered by a semi-cartilaginous membrane of a line and a half in thickness, the remainder of the texture of the lung studded with tubercular deposits, and completely impermeable to the air; right lung partly adherent, but comparatively healthy.

Abdomen.—Peritoneal cavity containing a great quantity of gas, also a mixture of serum and fecal matter. All the convolutions of the intestines adherent to each other, and forming a mass, firmly glued together, in the centre of the abdomen. Liver covered by false membranes, and adherent to the surrounding parts; its structure, as well as that of the spleen, filled with tubercles. Mucous membrane of the stomach thickened and brittle. Internal surface of the ilium and colon ulcerated. The intestinal tube had been lacerated to such a degree by the attempts made to unravel the convolutions, that it was impossible to ascertain the seat of the perforation, through which the fecal matter had escaped into the peritoneal cavity, and caused acute inflammation of its lining membrane. Several of the abdominal ganglions had degenerated into tubercles. Nothing remarkable in the cavity of the cranium.

We should notice in this case the influence exerted over the production and progress of the tubercles by the scrofulous constitution of

the patient, by masturbation, and by the diseases which had preceded the invasion of the cough, especially the measles. On the admission of the patient no doubt could exist as to the presence of a tubercular affection of the lung. Auscultation and percussion of the thorax, at the same time that they confirmed the diagnosis, indicated a perforation of the pleura-pulmonalis communicating with a tubercular excavation. The sudden attack of acute pain on the left side of the chest, with tympanitic sonorousness and absence of respiratory bruit and metallic tinkling, proclaimed the existence of pneumo-thorax. In all the cases where the latter symptom supervened under similar circumstances, which have been mentioned by Laennec, Andral, and Louis, death has soon taken place. In the present instance it is not surprising that dulness of the left side should have succeeded tympanitic sonorousness, and that all the other signs indicating air in the pleural cavity should have disappeared. The admission of air into that cavity, assisted probably by the effusion of a certain quantity of tubercular matter, caused inflammation of that membrane, which produced exudation of a pseudo-membranous structure, closing up the fistula. In the abdomen, the tubercular peritonitis, which had been indicated by the tumefaction of the region and the occasional vomiting; the ulcerations so frequent in these phthisical cases; lastly, the acute peritonitis following the perforation of the intestinal canal, and constituting the immediate cause of death, are all circumstances worthy of notice. It might be added, that tubercular peritonitis is of common occurrence in children.

Affection of the Liver resembling Phthisis Pulmonalis — Pleuro-Pneumony — Death — Autopsy.

André Guézin, 11 years of age, came into the hospital the 29th of February. Has lost all his relations from phthisis pulmonalis; has been long addicted to masturbation. On the 14th of February was taken with acute pain in the right side of the chest, which lasted till his admission, accompanied with accessions of fever, cough, and uneasiness. When he came in, the symptoms were decubitus on the back, acute pain under the right breast, increased by percussion, &c.

U U

cough, or by deep inspiration; respiration short, and incomplete; no dulness or oegophony; mucous râle, especially under the clavicles; dry cough; skin warm; pulse 120; tongue moist; bowels torpid; countenance pale. (Mallow, gum julep, cataplasms to the part affected, milk.)

March 3rd.—Auscultation and percussion indicate effusion on the right side of the chest, complete dulness of the inferior half. (Emplastrum picis Burgun. to the right side.)

On the 8th, pain in the right side completely dispelled; effused fluid re-absorbed, and much less dulness. The patient experiences no sufferings, but is extremely pale and weak; inferior extremities slightly anasarous; abdomen tumefied.

18th. Cough increased; fever intense with hectic flush of the face; sputa viscous, frothy, and of a rusty hue; pain which had left the right side is now seated on the left; respiration 36, pulse 124. (White oxide of antimony was prescribed.) The fever, dyspnoea, pain, cough, and expectoration continued to increase in severity. On the 26th bronchophony had succeeded the râle crepitant; pulse 140, respiration 48; some delirium accompanying the febrile accession, which is followed by profuse perspiration.

These symptoms continued to increase, and on the 29th the patient died.

Examination of the body twenty-five hours after death.—*Neck and Thorax*—Cellular tissue œdematous; mucous membrane of the larynx and trachea pale but not ulcerated; bronchi engorged with purulent mucus; right lung adherent; pleura pulmonalis covered with soft false membranes, but free from effusion; right lung permeable, except at the centre of the upper lobe, where it was hepatized; pulmonary texture friable, and exuding by pressure purulent fluid which sinks in water; pericardium contained two ounces of yellowish serum.

Abdomen.—Peritoneal cavity containing two pints of yellow serum; liver rather larger than natural, and containing in its right lobe a number of excavations filled with pus, and lined by false membranes; gall-bladder much contracted; spleen larger and softer than natural.

The severe disease of the liver in this case had not been indicated during life by any cha-

racteristic sign; the pain complained of on the right side was situated on a level with the breast, and plainly referred to phlegmasia of the pleura; every thing tended to prove the existence of an incipient tubercular affection; the œdema of the lower extremities, and the accumulation of serum in the abdominal cavity ought to have drawn attention to the state of the liver, but the dropsy became considerable only a few days before death, at a time when inflammation of the lung, which was rapidly progressing, threatened the life of the patient, and excluded the consideration of all other symptoms. As to the duration of the disease of the liver, nothing satisfactory could be ascertained. A friend of the patient's mentioned after his death, that he had a severe fall three weeks previous to his admission; this might have had some connexion with the affection of the liver, which seems to have preceded the inflammation of the chest, which latter was the cause of death. The irregular accessions of fever experienced anterior to, and during his continuance in the hospital, were symptoms of an incipient tubercular affection, or an internal suppuration. They might have been attributed to the formation of the abscess in the liver, but the latter disease is so seldom met with in children, that, out of 240 post-mortem examinations at this hospital for the last twenty-years, only one instance of it has been met with.

The probable duration of the Lives of Medical Practitioners.

Professor Gasper, of Berlin, states that the ordinary duration of life in the human being is seventy years; but that a very few medical practitioners attain this age, and scarcely one out of fifteen advance so far as eighty. Half the total number of practitioners perish before fifty. There is no profession, he states, in which there exists so much moral contention and fatigue, or which permits of less repose, the regularity of which is so essential for the interior as well as the exterior of life; none which exposes the body to such disastrous influences of the atmosphere, to such disturbance of nocturnal repose, to such watchings, to such irregularity of living, to such disorders of the digestive organs, and to such moral affections. To this I can add, he continues, the unknown number of medical men

who perish from contagion. This statement confirms the truth of the old adage,

"*Medicè vivere est miserè vivere.*"

Influence of the Potatoe on the Health of Sailors.

The potatoe is an indispensable provision on board of ships, not only to vary the aliment, but to mix dry and fresh vegetables together; it modifies also the ill effects of salt meat on the constitution. This vegetable, eaten in a crude state, is very agreeable to sailors, especially if they have been deprived of fresh legumes for a long time; moreover, it is antiscorbutic. The heat of vessels, when situated between the tropics, causes it to bud; the sprouts, however, are not good, in consequence of an acrid principle that they contain; but during the vegetation of this plant, the tubercle becomes more fresh and sweet, and sailors find it more palatable than the potatoe that does not germ.

The Chemical Changes produced in Coffee by Sea Water.

M. Girardin, Professor of Chemistry, and Member of the Committee of Salubrity at Rouen, has, by request of the Mayor of the town, analysed coffee thus injured. It appears from the result of this examination, that its chemical composition is much altered, as many of the constituents contained in the coffee seed, especially *caffèine*, were not detectable; and the others had become so modified, that by re-actives their proper characters were not to be distinguished. The coffee examined contained no salts of copper, or any other metal, though it had remained at the bottom of the vessel coated in this metal. Nevertheless, he concluded that such injured coffee ought not to be exposed for sale. The same chemist had to examine a succedaneum of coffee, sold by a grocer at Rouen, and found it composed of burnt rye. A person named Kint, in the United States, took out a patent for a confection of coffee composed of the same class of grain, to which he added some eggs, and a little burnt skin of the cod-fish.

A New Invented Oven for Baking Bread.

PROPOSED BY M. SOCHET.

This oven is to consist of an horizontal cylinder, made from cast iron, the bread is to

be placed on an immoveable partition put in its centre; the tube, by receiving a circular motion, will successively expose the whole of its circumference to the heat of wood, charcoal, or any other kind of fuel that may be placed exterior to it.

MR. BANNER ON THE TREATMENT OF ABORTION.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—In my paper on Uterine Hæmorrhage, published in the Liverpool Medical Journal for June, it is stated in my remarks on Case 2, that "had the *hand* been introduced earlier there is every reason to suppose the cause of hæmorrhage would have been removed." In the relation of the case I particularly allude to the *cautious* introduction of the *finger*; and in another part of my paper I make the following observation:—"It occasionally happens that there is difficulty in reaching, with the *finger*, sufficiently far into the uterus to remove its contents. The introduction of more than *one finger* is of course attended with greater pain; fortunately, however, this is seldom necessary. The membranes, placenta, or fœtus, are generally felt protruding through, or contained just within, the orifice." It will be seen, therefore, that in mentioning the introduction of the *hand* in the passage alluded to, an error of expression has occurred. I think it but fair to myself to state this, as you have, in condescending to notice my paper in the 123rd No. of your Journal, laid particular stress on the impracticability of introducing a *hand* into the uterus in the early period of gestation. In this I quite agree with you; I think it quite impossible to introduce the *hand*. In Case 2 it was only necessary to introduce *one finger*, as will be found sufficient in the majority of cases, requiring interference. You state also, in reference to Case 2, "were we consulted in this case we should have acted thus: as the evacuation was sanguineous and not catamenial, and as the patient was so young, we should, in the *first instance*, have instituted a vaginal examination, to ascertain the exact state of the os uteri."

As my object in writing the paper on this subject was more to gain information than to

give it, I shall feel obliged by your informing me what would be your object in ascertaining the state of the os uteri; and whether, on finding the membrane, &c., protruding or just within the orifice, you would remove it? You also state, that, after making this examination, "you would have plugged the vagina." Am I to understand, that in all cases where there is discharge of blood from the vagina (however slight) you would institute an examination and plug the vagina. In the case related, it was not until the eleventh day that the symptoms appeared urgent. In Case 1, your practice was adopted. You go on to observe, "suppose a membrane had been developed in the os uteri, how, we beg to inquire, could it produce such profuse hæmorrhage?" In answer, I would extract the following passage from my paper:—"It is a question with many, whether so small a substance as a portion of the membrane, in the early stage of gestation, can be a cause of irritation; yet in how many instances the uterus appears to contract (at least we are justified in supposing so from the repeated expulsion of coagula accompanied with pains), and which generally cease on the removal of the exciting cause; if the substance were more bulky, the chances of expulsion would be greater. It appears sufficient to produce irritation, yet too small to be acted on." That it is possible to reach the uterus with the finger, in the early periods of gestation, you must admit. In proof of the low position of the uterus at this time, is the symptom of tenesmus, and also of incontinence of urine, from pressure of this viscus on the neck of the bladder, which are generally present in cases of early abortion, produced probably from a tendency to bear down. I was not aware before reading your last number, "that the ergot of rye will irritate the uterus from the moment of conception." I have not had much experience in the use of it; the observations I have made on this drug were drawn from the result of my own practice. I feel the presumptuousness of differing in opinion with you on these points, for my experience in the practice of midwifery must be very limited when compared with yours, yet so satisfied am I of the propriety of the practice recommended by me, that I have considered it a duty to write to you on the subject, nor shall I be induced to alter the practice, unless stronger

reasons than those given by yourself be deduced. My conclusions were come to from observation from *facts*, and until stronger reasons be given for desisting in the method than those I forward in support of it, I must be excused my adherence to it. Allow me to express my thanks for the very courteous manner in which you have noticed my remarks, and subscribe myself,

Your most obedient servant,

JOHN M. BANNER.

Liverpool, June 13, 1834.

Mr. Banner asks us, "what would be your object in ascertaining the state of the os uteri, and whether, on finding the membrane, &c. protruding, or just within the orifice, you would remove it?" In reply, we state that our object would be to ascertain whether the os uteri was dilated or not, or contained an embryo, coagulum, or membrane, and if so, to remove any one of these, and stop the hæmorrhage at once. But if we could not detect the cause of hæmorrhage, we should have accurately plugged the vagina, and arrested further loss of blood; and, if the ovum were not expelled, prevented abortion. The tampon, or plug, was especially necessary in the case alluded to, because ordinary means had failed to arrest the hæmorrhage. We beg to ask Mr. Banner in return, had he examined the first day, and discovered the membrane, would he not have removed it, as we would have done, and would not this have been as judicious as to wait until the eleventh day, when asphyxia was approaching, and when, after the removal of the membrane, life could only be saved by transfusion? We refer him to any recent work on obstetrics, either foreign or national, for the confirmation of our opinion. We might quote many, but we shall content ourselves with an extract from the able and judicious work by Mr. Ingleby. Speaking of early abortion, Mr. Ingleby observes, "When flooding threatens to be fatal, the tampon, or plug, by staunching the flow of blood, is at once effective and immediate in its action. This grand agent, though noticed by many of the earliest writers, was not applied at all conformably with the principles of science, until advocated by Leroux. It is evident, however, that the efficacy of the tampon is far from being duly estimated, even

at the present day, notwithstanding all that Dewees, Burns, and other eminent modern practitioners have adduced in its favour*."

"The plug, or tampon, recommended by Hippocrates, Moschion, Paulus Egenetus, Hoffman, Desormeaux, Lachapelle, Capuron, Velpeau, Duges, Smellie, Leroux, Denman, Hamilton, Burns, Merriman, Dewees, &c., is now generally employed †."

Mr. Banner inquires, "am I to understand that in all cases where there is discharge of blood from the vagina (however slight), you would institute an examination and plug the vagina? In the case related, it was not until the eleventh day that the symptoms appeared urgent."

In reply, we cannot but observe that the above question, which is a general one, is irrelevant to our remarks on the practice in the individual case which elicited our comments; but nevertheless we shall answer it. In every case of threatened abortion, we would institute an examination for the reasons already assigned; but we should not use the tampon when the discharge was slight, the os uteri undisturbed, the uterine action insignificant, and most probably controllable by rest and opium. But in a case like that which we criticised, in which a delicate woman, aged 28, "had parted with small coagula, and on the second day was restless, complained of heat of skin and thirst, the pulse quick, the discharge florid, small in quantity, but constant; and she had parted with several clots and shreds, which had been thrown away;" we most assuredly would have plugged the vagina, nor would we be content with the following plan. "She was desired to remain in the recumbent position; febrifuge medicine was ordered, with acid drinks." Neither would we have neglected to visit her until the tenth day, while "symptoms continued, and the patient became gradually weaker; the hæmorrhage had increased, the pulse had become more irritable, the patient more restless." Now, we repeat,

* A Practical Treatise on Uterine Hæmorrhage in connexion with Pregnancy and Parturition. By J. T. Ingleby, M.R.C.S., &c., Lecturer on Midwifery at the School of Medicine in Birmingham. 1832.

† A Manual of Midwifery, &c. By M. Ryan, M.D., &c. 3rd edition. 1831.

that if the vaginal examination had been made at the first visit on the second day, instead of on the morning of the eleventh, the powers of life would not have been prostrate, or transfusion, the ultimum remedium, necessary at all. We believe it is an axiom in obstetrics, that the treatment of abortion is divided into preservative, palliative, and active. We ask the experienced obstetrician, which plan of treatment was adopted in the case under notice, by leaving the patient from the second to the tenth day without medical aid? Yet our opponent is so satisfied of the propriety of his practice in this case, that he has considered it a duty to write to us on the subject, and adds,—“Nor shall I be induced to alter the practice, unless stronger reasons than those given by yourself* be deduced; my conclusions were come to from observation from facts, and until stronger reasons be given for desisting in the method than those I have brought forward in support of it, I must be excused my adherence to it.” Our conclusions, too, are drawn from facts, and from the multiplied experience of the numerous obstetricians whom we have quoted; and until stronger reasons be given, we shall continue the practice we have recommended. Mr. Banner, however, agrees with us on an important point,—that the introduction of the hand in the early months of utero-gestation is impracticable, and that in advising it “an error of expression has occurred.” We are glad it is so: but Mr. Banner should be cautious in his expressions. Neither was he aware of the power of the ergot in exciting uterine irritation from the moment of conception; and he has not had much experience in the use of it. We are sorry for it, because his remarks were calculated to depreciate its value; and as we have employed it in a vast number of instances, and invariably with success, we regretted, on the grounds of humanity and the fame of our art, that so powerful and efficacious a remedy should be doubted. We have to state that our remarks on it, in No. 123, have already elicited fourteen letters from different places, requesting us to give an account of the mode of keeping it; and though we are extremely reluctant to appear in the

* Mr. Banner has addressed the above communication to Dr. Ryan.

pages of this Journal but as seldom as possible, we cannot but comply with so many requests.

We now terminate Mr. Banner's controversy, in the friendly spirit in which we invited our comments on his paper; and if he be not satisfied, we cannot help it. Our duties, as journalists, and his, as a respectable, zealous, and efficient provincial surgeon, are very different. We have this kingdom, all Europe, and our transatlantic brethren to satisfy; he has to maintain the validity of his own opinions.

Review.

The Natural History of Animalcules; containing Descriptions of all the known Infusoria, with Instructions for procuring and viewing them, &c. Illustrated by upwards of 300 figures, magnified on steel. By ANDREW PRITCHARD, Esq. 8vo. pp. 196. London: 1834. Whittaker and Co.

THE author of this work is entitled to great praise for the numerous improvements he has made in the construction of microscopes, whose almost incredible powers bring under our observation the ultimate structure of an endless variety of objects in natural history, among which those called animalcules are not the least remarkable. Myriads of these exist in a single drop of water, performing their functions with as great facility and freedom, as if the range afforded them were the boundless ocean. The knowledge of this fact must be interesting to the mind of every one who is accustomed to meditate on the works of nature, "and to recognise and adore the hand that guides her through all the vast variety of her stupendous operations." Our author proceeds thus:—

"As our acquaintance with the minute portions of the creation is exclusively dependent upon the properties of the microscope, every refinement of this interesting and valuable instrument must necessarily contribute something to our stock of knowledge on the subject; and indeed it is entirely owing to the very great perfection which it has now acquired, that a fresh spirit of research is widely extending itself,—a research into those recondite truths which may lead not merely to

the gratification of our curiosity, but to some of the most important and scientific results."

After noticing the imperfect works of Müller, Ehrenberg, and Cuvier, which touched but slightly on the structure of animalcules, our author maintains, that an internal structure is discerned in some, equal to, if not surpassing, that of the large in vertebrated animals, and comprising a muscular, nervous; and, in all probability, a vascular system.

The mode of examining these objects is thus described:—

"In the selection of vegetable substances for infusions, such as stalks, leaves, flowers, seeds of plants, &c., care must be taken, that there be no admixture of quinine in them, or the intention will be frustrated. Immerse these, whatever they may be, for a few days, in some clear water, when, if the vessels which contain them be not agitated, a thin pellicle or film will be discerned on the surface, which, under the microscope, will be seen to be inhabited by several descriptions of animalcules: the first produce are commonly those of the simplest kind, such as the monads. In a few days more, their numbers will increase to such an amazing extent, that it would be utterly impossible to compute those in a single drop of the fluid. After this, again, they will begin to diminish in numbers, and I have generally observed them supplanted by others of a larger species and more perfect organisation, such as the cyclidia, paramesia, kolpodas, &c. It is worthy of remark here, however, that in their production they do not pursue any regular order, even in similar infusions. If the vessel be large, and the circumstances under which it is placed sufficiently favourable, a still higher description of animalcules will succeed, viz.—the vorticella, and, lastly, the brachioni; and thus a single infusion will repay for the little trouble of making it, with a great variety of species. Water in which flour has been steeped will be found to abound also with animalcules; and it is remarked by G. Leach, Esq., that the leaden troughs constantly appropriated for birds to drink out of, contain several descriptions of them, and more especially those of the wheel genus. In ponds, too, especially in the shallow parts, near their edges, and in the immediate vicinity of water-plants, prodigious quantities of all kinds may be easily procured; so that possessing, as we

do, such myriads of them all around us, that they impregnate almost every thing that we eat and drink, touch and breathe, an anxiety to know more about them, and the effects they produce, cannot but be regarded as rational and laudable."

The varied forms of these singular beings are illustrated by plates, and are said to be the following:—

"By a careful inspection of the drawings, it will be noticed that some animalcules resemble spheres, others are egg-shaped; others again represent fruits of various kinds; eels, serpents, and many of the invertebrated animals; funnels, tops, cylinders, pitchers, wheels, flasks, &c., &c., all of which are found to possess their own particular habits, and to pursue a course of life best adapted to their peculiar constructions: thus, for instance, while some move through the water with the greatest imaginable rapidity, darting, leaping, or swimming, others merely creep or glide along; and many are altogether so passive that it requires long and patient observation to discover any of their movements at all. One description are perceptibly soft, and yield easily to the touch; another are covered with a delicate shell or horn-like coat. Of the latter order there are different degrees of density, as in the volvox, gonium, &c., where the envelope is comparatively thick; and where, strange to say, the internal substance separates by the mode of propagation into several portions, forming so many distinct young ones, which, at their birth, burst the envelope, and the parent becomes entirely dissipated. In others of this order the shell is merely a plate covering the body, resembling that of the tortoise: sometimes it includes the body, so as to leave only two small apertures at the extremities, and at others it is bivalve, and encloses the creature like that of the oyster or muscle."

The singular methods of propagation of these animals demand notice.

"1. Animalcules propagate by a spontaneous scissure, or division of their bodies into two or more portions, each one forming a new creature, which, on its arrival at maturity, pursues the same course. These divisions take place in some genera symmetrically, as in the gonium, &c.; in others, by transverse, longitudinal, or diagonal sections.

In these latter cases the produce have forms differently proportioned from those of the creatures from which they spring; for instance, figure 160 represents the young of 159, engendered by a transverse division: this circumstance, we may observe, renders it sometimes difficult to determine the species. 2. They propagate, in the manner before mentioned of the volvox and some other genera, by a distribution of the internal substance of the parent into a proportionate number of young ones, all of which at their birth issue forth, and leave behind them nothing but the envelope, soon to be dissolved. 3. They are produced from germs, shooting forth from the parent's sides, as represented by fig. 218, &c. 4. From spawn, which, in the act of being shed, carries along with it a portion of the parent animalcule, as shown by fig. 80."

Those interested in the study of natural history will find much curious information in this work.

COLLINS V. COLNAGHI.

THE following decision is extremely important at the present period, when a Parliamentary Committee is engaged on Medical Education. If Scotch Degrees in Medicine are no proof of professional acquirements, it is manifest that they should be, and moreover that Englishmen ought to be enabled to graduate in their own country without the absurd and tedious systems of Oxford and Cambridge;—in fact, medical degrees ought to be conferred in London:—

Lord Denman observed—"The Court had taken time to consider the question raised in this case, which was, whether a person, who had obtained the degree of doctor of medicine in a Scotch University, in the College of St. Andrew's for instance, could, without obtaining a licence from the College of Physicians in London, maintain an action, in the character of a physician, in this country. Their Lordships were of opinion that he could not; and they came to that conclusion on the words of the statute 14 and 15 Hen. VIII., c. 5. The first section declared who should practise as physicians in London. The third section of that statute recited, that in the dioceses out of London it was not likely there would be found

men fit to practise medicine, as required by the first section; and it enacted, that henceforth no man should practise in such place "without a letter of licence from the College of Physicians, except the graduates of the Universities of Oxford and Cambridge, which both accorded him all things for his advantage without any grace." This statute vested the power of granting such a licence in the College of Physicians; and Lord Holt, and the rest of the Court, in the case of the College of Physicians v. Lovett (Lord Raymond's Report, 472,) decided that even a graduate of the University of Oxford or Cambridge could not practise as a physician within London, or seven miles of it, except by letters of licence from the College of Physicians. A similar opinion was also held in the case of the College of Physicians v. West, in 10 Modern Reports, 353, and those decisions must bind the Court in the present instance. In the latter of these cases the Court adopted the opinion, that, by the last clause in the statute, none should practise in the country without a licence from the President and three Elects, unless he were a graduate of one of the Universities of Oxford and Cambridge. It followed, from the authority of that case, that the plaintiff here had no right to practise as a physician in the country without a licence from the College of Physicians, although there was not in the statute any penalty imposed upon him for so doing. This action, it was therefore clear, could not be maintained by him in respect of slander upon him in a profession which by law he had no right to exercise. In the case of Smith v. Taylor, 1 New Reports, 203, was a dictum of Lord Chief Justice Mansfield, in which he was supposed to say, that since the Union a degree, conferred by the Scotch Universities, had the same effect as a degree conferred by the English Universities. The Court did not think that Lord Chief Justice Mansfield meant to imply any such thing; but, if he did, they were of opinion that the dictum was totally unwarrantable by any authority. The verdict given for the plaintiff, with 20*l.* damages, must therefore be set aside, and the judgment of the Court must be given for the defendant."

London Medical & Surgical Journal*Saturday, June 21, 1834.*

**DUTIES OF MEDICAL PRACTITIONERS
IN CASES OF INSANITY.**

MUCH surprise and interest have been excited by a police report, which appeared in the newspapers in the course of the last week. The owner of a house in the Hatton Garden district represented to the Magistrates of that office, that a young man, of apparently peaceable and quiet demeanour, had lately taken lodgings in his house; and that a party of men entered the house at a late and unseasonable hour of the night, and immediately proceeded to his lodger's apartments, whom they took into their custody, and finally carried him off. Upon being remonstrated with they produced, he alleged, some authority, or certificate, from Dr. Burrows, and said the young man had lately escaped from a lunatic asylum, to which they intended taking him back.

It was the duty of the Magistrates to have inquired more minutely into the circumstances, and to have satisfied the public, if they were satisfied themselves, that the liberty of this person was not restrained without a legal cause. After the late astonishing affair of Mr. Gee, to say nothing of former malpractices under the imputation of lunacy, it was not unreasonable to expect a little attention to such a statement as was made before them.

We are glad to find the public alarm has been since quieted by a paragraph in *The Times* of Wednesday, which explains some of the mystery attached to the original story, and relieves Dr. Burrows, who was the only party named, and others, from the imputation of lending themselves to an illegal transaction. The amended statement is as follows:—

"We are assured by respectable parties, that the unfortunate gentleman, whose case was inquired into at Hatton Garden Police Office on Friday last, and adverted to in a letter, signed Veritas, in *The Times* of yesterday, has never been placed in a lunatic asylum. By the desire of his father, who is a physician, and, after the careful examination of his case by another physician, eminent in his knowledge of diseases of the mind, this young gentleman has been placed under temporary restraint in a private lodging until he recovers from his present state of excitement. We never meant to insinuate that the parties concerned were to blame, but merely that the Magistrate disposed of the matter too hastily."

It may be desirable, before we dismiss the subject, to point out to medical practitioners their duty as prescribed by the legislature, when they are called upon to act in such trying emergencies, as to pronounce a human creature insane and unfit to be entrusted with his liberty. The act of parliament, by which these duties are pointed out, is the 2nd and 3rd W. IV., c. 107. It was passed on the 11th Aug. 1832, and is in force for three years and from thence until the end of the next session. In the interpretation clause we find that the word "Physician" in the act includes a Fellow or Licentiate of the College of Physicians; the word "Surgeon," a member of the College of Surgeons; and the word "Apothecary," any person authorised to practise under the 55th Geo. III., c. 194, or the 6th Geo. IV., c. 133. It is plain, therefore, that a mere graduate of any of the Universities is incapable of legally exercising any of the powers given by this statute. Inattention to this may cause very serious consequences. If a gentleman, with an Edinburgh degree only, should presume to give

the certificate we shall hereafter mention, he would render himself liable to an indictment for a misdemeanour.

We shall say but little on all that part of the act, which relates to the Metropolitan Commissioners and the Licences of Lunatic Asylums, and confine ourselves principally to the duties and responsibilities of medical practitioners.

The 27th section enacts that no person (not being a parish pauper) shall be received into any lunatic asylum in England without an order, according to a certain form annexed to the Act under the hand of the person by whose direction such insane person is sent; nor shall any such person be received into any such house without a medical certificate of two physicians, surgeons, or apothecaries in manner directed by the Act.

The 28th section enacts that the medical certificate shall be according to a form annexed to the Act, and shall be signed by two medical practitioners, not being in partnership, and each of them being a physician, surgeon, or apothecary, who shall have separately visited and personally examined the patient to whom it relates not more than seven clear days previous to such confinement; and such certificate shall be signed and dated on the day on which the party shall have been examined, and shall state that such person is insane and proper to be confined. And every such certificate shall, if the same be not signed by two medical practitioners, state the special circumstance which shall have prevented the patient being visited by two medical practitioners; and any patient may, under such special circumstance, be admitted upon the certificate of one medical practitioner, provided such certificate shall be further signed by some other medical practitioner within seven days next after

the admission of such patient. And any person who shall, knowingly and with intention to deceive, sign any such medical certificate, untruly setting forth any of the particulars required by the Act, shall be deemed guilty of a misdemeanour; and no physician, surgeon, or apothecary shall sign any certificate of admission of a patient to any licensed house, who is wholly or partly the proprietor, or the regular medical attendant of such licensed house; nor shall any physician, surgeon, or apothecary sign any certificate for the reception of a patient into any such house of which his father, son, brother, or partner is wholly or in part proprietor, or the regular professional attendant, on pain of being deemed guilty of a misdemeanour.

To complete our survey of this important act, we must add a few particulars relative to some other points. The administration of lunatic asylums in the London district is vested in certain commissioners, of whom not less than four or more than five must be physicians, and two barristers. These commissioners are empowered to license all houses for the reception of two or more lunatics in their district. In all other parts of England the licence is obtained at the quarter sessions. The justices at the Michaelmas quarter sessions appoint three or more justices, and one or more physicians, surgeons, or apothecaries, as visitors for the county. No person, except a guardian or relative, who does not derive any profit from the charge, or a committee, is authorised to receive or board any insane person in a house not licensed without the order and medical certificate already described. To guard against a possible abuse of authority, the Lord Chancellor is empowered to appoint a person to visit and examine any person confined as insane in the care of any guardian or relative.

To conclude: if any action is brought for the confinement or ill-treatment of any of his Majesty's subjects, insane or alleged to be insane, the parties complained of must justify their proceedings by the course of the common law, and derive no new justification from their being able to prove that the person had been confined upon such order and certificate as we have already described. The absence of an order or certificate, except in the case of a guardian or relative not deriving a profit, makes the confinement a misdemeanour under all circumstances; but, though the order be given and the certificate signed, they will not warrant any restriction of liberty. They do not alter the common law responsibility of parties for their own acts. To justify restraint, a jury must be satisfied there were reasonable grounds to believe the person restrained of unsound mind, and that the party acted in that belief.

This Act of Parliament does not apply, except in visitatorial powers, to the Public Lunatic Asylums.

MEDICAL FEES.

A PURE conceives it would be degradation to accept a fee less than a guinea, because that is the *least* fee he is likely to be offered by the *aristocratic* patients, of whose peculiar patronage he is so fond of boasting, (see Medical Pamphlets under the auspices of Pall Mall *passim*). Of course there is no limit on the other side, and woe betide the reputation of the noble peer, or wealthy commoner, who thinks, nevertheless, of offering him a mere guinea. This rule had another extremely beneficial effect for the *Pure* in high practice; it secured him a monopoly in his own class. The young practitioner, who, without the long experience of the heads

of the profession, was still perfectly competent to discharge his professional duties, finds himself excluded from practice till his head turns grey, because his valuable services can not be procured for less than the *minimum honorarium quiddam*, for which the celebrated Doctor So-and-so may be had.

It was the operation of this system—a part of the prime monopoly and extortion, that drove the respectable and industrious middle classes of society to seek medical relief in other and more reasonable quarters. Hence sprung the trading principle of calculating upon the profits of drugs as a remuneration for the expense and care of a medical education, and the anxieties of medical practice. Out of evil has grown good: the general practitioners of the present day, with some exceptions in the lowest quarters, are awake to the mischiefs of the trade system, and, with feelings truly honourable, are anxious to disabuse the ignorant portion of the public of its prejudices, and convince it it is better to pay a moderate sum for good advice than for bottles full of drugs. We are confident the fee system must be remodelled. The general practitioner must be allowed to charge a reasonable fee for his attendance, and the guinea system must be abolished.

The following passage from a French paper will show how they manage these things in France:—

“Madame Montessu, the dancer, who was for some time at the King’s Theatre, was lately sued before the Civil Tribunal at Paris for the amount of a doctor’s bill. Although the plaintiff, M. Melicque, is a man of some eminence, it appeared that he only charged the fair defendant *three francs a visit in the day and six francs for a nightly visit*. Even this sum, however, was thought to be too large by the de-

fendant, who resisted it on that ground. The Court, however, did not partake in the opinion, and she was ordered to pay the amount of the bill, 200 francs, and the expenses.”

SIGNOR MOSCATTI—PHRENOLOGY AT HOME.

Our pages have never been illuminated with the Signor’s critiques or phrenological dissertations. When the quarrel between him and Dr. Elliotson was fresh, we thought it utterly unworthy of public notice, nor would we, for the sake of a private grudge, annoy any man on earth in that tender point,—his vanity. We understand those, who had reason to be dissatisfied with the use made of their names in the business, are content with Dr. Elliotson’s explanation,—so let it rest. We must decline publishing the Signor’s letter. Dr. Elliotson has acquired some experience in Capital Lions. As the Signor is, it seems, a lettered man he will understand these lines—

Solutos

Qui captat risus hominum, famamque dicacis,
Fingere qui non visa potest, commissa tacere
Qui nequit; hic niger est.

The expression of the natural sentiments is the same at all times and in all places. On the coast of Africa the white man is said to grow *black* when his moral character becomes thoroughly depraved.

Touching phrenology, we advertise a certain lecturer and his *fair* class, that they shall find us *at home* if much more of their pranks get abroad.

PROGRESS OF THE PARLIAMENTARY COMMITTEE ON MEDICAL EDUCATION.

MR. WARBURTON continues as zealous and as indefatigable as ever in the great cause of humanity—the reform of the medical profession. He has now collected a mass of evidence

relating to the two Universities, the Colleges of Physicians and Surgeons, and the Apothecaries' Company in this section of the kingdom, which of itself would inevitably lead to an improvement in the education of medical practitioners of all grades throughout the British empire. He has not as yet commenced with the examination of the Scotch or Irish corporators, nor is it likely he can during this session of Parliament, on account of a speedy prorogation. Nevertheless they cannot escape exposure.

Our remarks on the expediency of examining some lecturers belonging to what are superciliously and improperly called private schools, had the desired effect. Dr. Epps, Mr. Dermott, and Mr. Hetling of the Bristol Medical School, have been examined since our last, and also our colleague Dr. Ryan. Their evidence went to shew the comparative advantages and disadvantages of the favoured and unfavoured schools; and in addition, our opinions on reform, with which our readers are well acquainted, were fully submitted to the Committee. The ability, ingenuity, and extraordinary knowledge of medical abuses, displayed by the honourable chairman, have elicited the highest praise and the greatest respect from the crowded auditory in daily attendance. Every one is surprised at the extent of his information on the defects in every one of the corporations.

NEW REMEDY FOR INTERMITTENT FEVER.

DR. GILLESPIE, Physician to the Baltimore Infirmary, prescribes the following pill, given an hour and a half before the cold or shivering fit, as effectual in preventing it, and also in intermittent neuralgia.

R. Camphoræ, gr. ij; opii, gr. iss; hyd. subm. gr. v.

He thinks that the impression made on the nervous system by it is greater than the miasmata which produce intermittents.—*American Journal of the Medical Sciences.*

This is only a modification of our own plan, first tried by Dr. Trotter and Dr. Lind, namely, by exhibiting a full dose of laudanum an hour before the accession of the cold fit, a practice generally adopted in this country.

We cannot help observing, also, that so small a quantity of camphor as two grains can have little influence, and the calomel still less. We have, however, respectable authority in favour of the combination, and shall try it on the first opportunity.

GASPARD HAUSER.

THE history of the unfortunate Gaspard Hauser has given rise to so many absurd inventions, that the Bavarian Government have thought proper to order the seizure of every pamphlet which contains any thing respecting him. The relations and unknown murderers of Gaspard Hauser do not appear to be strangers to these productions, which are filled with the most contradictory versions. In some of them the unfortunate young man is represented as the persecuted and rejected heir of a princely family, and even of a reigning house; while others state that he was a maniac, and that having become the victim of the illusions which he had himself created, he terminated his life by suicide. Now that the patron of Gaspard Hauser, Lord Stanhope, has taken his departure, the King of Bavaria is the only protector of his memory. His Majesty has given orders that the investigation into all the circumstances shall be continued, and has given considerable sums of money for the purpose. The truth, therefore, is likely to be known, if truth can be elicited in a case where enthusiasm and party spirit have so much influence.

Foreign Hospital Reports.

HÔTEL DIEU.

Abscess in Front of the Axilla—Stagnation of Pus—Death—Autopsy.

ANNE COFFURANN, 30 years of age, of nervous temperament and feeble constitution, was admitted into this hospital, under the care of M. Sanson, December 26, 1833. In attempting to lift any weight she experienced acute pain in the superior part of the right side of the chest; there was great tumefaction in the right axilla, which was extremely painful, though the colour of the skin remained unchanged, accompanied with shiverings and fever. The danger of a deep-seated abscess was apprehended, though no fluctuation could be de-

tected; all means were employed to expedite the progression of the abscess. At first she was bled, and, in the course of five days, leeches were applied to the affected part, and baths were prescribed as frequently as she could bear them. At first, from this treatment, the symptoms became relieved, but in a short time they became worse, and fluctuation was evident.

M. Sanson endeavoured to ascertain the situation of the tumour, and believed it to be between the two portions of the pectoral muscles. It appeared to be immediately behind the axillary artery, which it had pushed forwards and outwards, and separated from the pectoral muscle and integuments by the coraco-clavicular fascia. From the depth of the abscess and its strong coverings anteriorly, M. Sanson feared that it would open into the cavity of the chest, or extend into the anterior mediastinum. He, therefore, wished to make an external opening as speedy as possible, though not the slightest inflammatory blush was perceptible on the cutaneous covering.

On the 6th of January, eleven days from her admission, he made an incision, two inches and a half in extent, dividing at first the integuments, then some of the fibres of the great and lesser pectoral muscles, when a small quantity of pus escaped from the orifice, in consequence of which, with a blunt pointed bistoury, the wound was enlarged, which allowed a free exit to the collected matter. The divided edges of the wound were separated by means of a dossil of lint; the pus that escaped was of a good consistence and healthy. The patient was much relieved, though she was still restless, and was unable to sleep.

9th. This morning she complains of pain on the right side of the posterior part of the chest, accompanied with diarrhoea. A starch injection was administered, which arrested the looseness, and leeches were applied to the painful part. The next evening the diarrhoea returned, an opiate clyster was administered, after which she obtained a comfortable night.

10th. Complains of a disagreeable odour from the suppuration; the wound to be washed with a mixture of the chloride of soda and water, and the bed to be sprinkled with the same fluid several times during the day. In the evening she became much worse, nausea and vomiting supervened.

In spite of all remedies the patient became weaker. Some wine was prescribed, of which she took but a very small quantity at a time. This appeared to rouse her from the lassitude and exhaustion of which she was suffering. A roll of lint was now placed in the axilla, and retained in this situation by means of a bandage, so as to approach the united edges of the wound. On the 16th all the symptoms appeared relieved; nausea and relaxation had ceased; strength much improved.

For some days the patient complained of slight pain in the cavity of the axilla, especially towards the edge of the omo-hyoid muscle. Every day this region was examined with the greatest care; skin remained unchanged; a probe was introduced into the wound, and directed towards the border of the omo-hyoid muscles, where she complained of the most suffering. No further diagnosis could be ascertained; the pain remained stationary.

28th. From the increase of symptoms a counter-opening was indicated. The application of compression was discontinued, in the hope of permitting the stagnant pus to escape by its own gravity, which however did not take place, neither was the counter-opening practicable from the deep situation of the abscess. For the sake of keeping up her strength, if possible, she was wheeled about in a chair, which, though it at first excited vomiting, appeared to revigorate her bodily powers; tongue brown and dry; no appetite.

All the symptoms evidently arising from the stagnation of pus, and the impossibility of making a fresh opening, M. Sanson decided on increasing the one already made. He thus prolonged the extent of the wound inferiorly, first ascertaining the exact situation of the artery; and by dividing the external lip of the wound beneath the lesser pectoral muscle, a large quantity of pus escaped; no hæmorrhage supervened. Some extract of bark was prescribed. The patient experienced slight alleviation; but, in spite of every precaution, the matter continued to collect, suffocation accompanied with cough came on, which daily appeared to increase, dyspnoea became intense, and on the 12th the patient died.

Autopsy.—On examining the abscess, a clot of blood was found in its cavity, and the axillary vein was perforated. The quantity of blood that had escaped could not be ascer-

tained, in consequence of being obliged to dislocate the clavicle, which much increased its quantity. The abscess extended from the sixth intercostal space to the clavicle, circumscribed internally, but externally the anterior walls were very thin, and extended between the greater and lesser pectoral muscles, also between the subscapular and serratus magnus. The intercostal muscles had become nearly absorbed, especially the third, through which the pleura could be observed; and, in one point, this membrane had contracted adhesions with the internal wall of the abscess. All the viscera were healthy.

HÔPITAL DES ENFANS MALADES.

*Cephalalgia—Paralysis of the left Side—
Strabismus—Prolapsus of the left Eyelid—
Death—Autopsy.*

— Patie, three years and a half old, who had enjoyed perfect health up to the first of March last, when she complained of pain in the head, became dull, morose, and exceedingly indolent. In the course of a month from the attack of cephalalgia, without any apparent cause, she was seized with vomiting, which continued for two days, and then disappeared. She was always troubled with acute pain in the head, which became at intervals much more severe; at this time a sensation of numbness attacked the limbs of the left side, and strabismus of the left eye followed. The numbness increased so rapidly, that, in the course of three weeks, locomotion, or walking, was impossible. Somnolency came on; irregular accessions of fever supervened; diminution of appetite; constipation. She was free from delirium and convulsive movements of the limbs. Before her admission into the hospital, she had been under medical treatment. Leeches had been applied to the head, and a blister to the back of the neck; tepid baths had been prescribed, with cold lotions to the head.

When admitted on the 6th of May, she was unable to lie on the back; countenance anxious and emaciated; distortion of the mouth; strabismus of the left eye, with prolapsus of the right superior eyelid; voice feeble, articulation difficult, with paralysis of the left limbs, the superior extremity somewhat contracted; no pain in the head; tongue moist, but covered

with a whitish mucus; no appetite; constipation; skin natural; pulse 92, scarcely perceptible.

Four grains of calomel were ordered to be given in two doses, and a clyster composed of two drachms of the leaves of senna with an ounce of mercurial honey; two setons were also ordered to be made behind the mastoid processes of the temporal bones; but, in consequence of the profuse suppuration caused by the blister, they were not applied. The symptoms continue the same; a scanty stool followed the clyster. (Six grains of calomel and rhubarb were prescribed, and eight leeches to be applied behind the ears.)

10th. No manifest change has taken place. (The camphorated liniment was ordered to be rubbed on the spine, and an infusion of the arnica montana was ordered.)

11th. Countenance pallid; incomplete occlusion of the right eye, strabismus of the left, the pupil of which is much dilated. All the other symptoms continue the same. (Sulphurous baths, infusion of arnica continued.)

21st. There is an erysipelatous blush around the wound, caused by the blister; extreme weakness; diarrhoea; evacuations involuntary.

22nd. Diarrhoea continues; stools bloody; difficulty of respiration; cough.

25th. Violet hue of the countenance; diaphragmatic respiration; tracheal râle; occlusion of the eyelids, by raising them the cornea appears dull, and the pupils somewhat dilated; pulse thready, very quick. Died during the day.

Necropsy eighteen hours after Death.—Head.—Dura mater healthy; soft fibrinous clots in the superior longitudinal sinus; arachnoid healthy; white substance of the brain not so elastic as natural; cortical substance healthy: an ounce of serous effusion in the lateral ventricles. On exposing the peduncles of the brain, the right was found much more voluminous than the left; in the substance of the former a tubercle about the size of a hazel-nut was discovered, in the cavity of which was found a poraceous fluid. The remainder of the brain and spinal marrow was healthy.

Some tubercles were found in the bronchial ganglions, also some miliary tubercles in the parenchymatous structure of the lungs.

There also existed a few tuberculous depo-

sitions in the mesenteric glands. The termination of the ileum presented ecchymotic patches, and there was slight *ramollissement* of the mucous membrane towards the termination of the colon. The other parts of these viscera were healthy.

We will here subjoin another case, the symptoms of which were similar, though the morbid production was situated in a different part of the encephalic substance.

*Paralysis of the Right Side—Death—
Tubercles of the Cerebellum and Annular
Protuberance.*

John Morque, ætat 11, had enjoyed good health till February, 1833. At this period he was attacked with brain fever, supposed to have been produced from fright; this affection lasted many weeks; and during convalescence his extremities became swollen, succeeded by abdominal effusion.

In the following August he came to Paris from Auvergne; the operation of paracentesis was performed, and nearly six quarts of serous fluid were discharged. A month afterwards the abdomen again became distended, and the same operation was again had recourse to, at this time seven quarts were evacuated.

A few days after the last operation, new symptoms supervened. The patient complained of an acute intermitting pain in the occipital region; strabismus, succeeded with imperfect vision, supervened, which at intervals, for a short period, was perfectly destroyed. Articulation of sounds became difficult, and stuttering was produced; the limbs of the right side became numb. In the course of three weeks the strabismus and difficulty of articulation subsided. During this time he had frequent attacks of vertigo and giddiness, and fell suddenly down, without losing any of his mental faculties. His sight, however, remained feeble, and his mouth became more and more drawn to one side. All mobility of the limbs of the right side was lost, which were cedematous and cold.

On the 21st of December he was admitted into the Hôtel Dieu, and was then in the following condition.

General emaciation; circumscribed blush on the cheeks; cephalalgia occupying the occipital region; incomplete palsy of the superior and inferior extremities of the right

side, there being a slight power of movement of the fingers and toes, but was unable either to raise the arm, or to keep it in that position when raised; sensibility very obtuse. Articulation of sounds very difficult; answers to questions rationally; right pupil very much dilated, left somewhat contracted; tongue wide and moist, covered with a thick fur; moderate thirst; appetite tolerable; tenderness on pressure about the abdomen, especially in the epigastric region; diarrhoea, stools of a light colour and foetid; skin hot and dry; pulse small, regular, 124; cough, no expectoration; slight difficulty of respiration; urine scanty, not albuminous. (Infusion of couch grass and gummy julep were prescribed.)

He remained much the same till the 31st, when violent delirium supervened, succeeded by a state of collapse.

Jan. 1st.—Countenance pale and anxious; voice feeble, articulation very incomplete; can scarcely protrude his tongue from the mouth; pupils equally contracted, but sensible to a bright light; pulse small, regular, but thready; urine and fæces pass involuntarily; abdomen much less distended than on admission.

White decoction; sinapisms to the feet; broth.

The symptoms continued to increase till the 5th, when death terminated the sufferings of the patient.

Autopsy.—Head.—Arachnoid healthy, but in the cellular tissue under this membrane some gelatinous and transparent secretion was perceived. At the anterior part of the left hemisphere this liquid was thinner, and more of the colour of wine; very slight effusion in the lateral ventricles; cortical substance healthy. At the external and lateral part of each lobe existed a tuberculous mass, about the size of a bean. These masses were of somewhat harder consistence than the substance of the cerebrum. The middle lobe of the cerebellum contained a tubercle of the size of a walnut; also in the annular protuberance there was found a tuberculous deposition, of a harder texture than the pons Varolii, and prolonged itself to the peduncle on the left side; in the right peduncle this deposition appeared also to exist, also in the superior wall of the fourth ventricle, surrounded by medullary substance.

Chest.—A similar tuberculous deposition

was found throughout the parenchymatous structure of the lungs.

Abdomen.—In the cavity of the peritoneum about a quart of serous fluid, of a brick colour, was contained; adhesions of the abdominal contents with the peritoneum. The surface of the peritoneum was of a darker hue than natural, more particularly above the umbilical region; several ulcerations about the intestinal tube were apparent, also in the ileo-cæcal valve. All the abdominal organs were healthy, with the exception of the left kidney and the bladder, the first forming a complete cyst, and containing in its ureter a calculus, the second, on its superior and posterior part, having a tuberculous ulceration.

CORRESPONDENTS.

Mr. Hodgson.—We published the list as furnished to us, but cannot return to it after so much time has elapsed.

C. S.—We shall insert a short article on the subject at our earliest convenience.

Cosmo.—The communication bearing this signature contains a great deal of sound sense, but it is written in so offensive a style, that we are surprised how the author could expect

any Journal to publish it. He may defend chemists and druggists as long as he pleases, but, in so doing, he surely violates all good feeling in heaping a string of the most opprobrious epithets on the physicians and general practitioners of this country. We agree with him that there are many conscientious and honourable individuals in the drug trade; but had he been present at the Parliamentary Committee last week, and heard the description of the frauds and villainy in the adulteration of medicines, he never could have written the paper before us. His knowledge must certainly be of a singular description, when he boldly asserts, contrary to all the evidence before Parliament, that chemists and druggists are better qualified to prescribe and compound medicines than general practitioners or apothecaries. We can inform him, however, for his satisfaction, that his friends will be compelled to receive a medical education and obtain a licence.

A Successful Candidate, who received a prize at King's College, cannot seriously suppose that we would re-publish the names of those who received medical certificates.

The Marquis of Moscati cannot expect that we could publish his letter, which refers to a controversy in other journals, and after these had refused to insert it. He will find his communication at our publisher's.

A. Z.—We are obliged to our correspondent for the trouble he has taken, but he has not shown the priority of claim he imagines. He will find by referring to vol. 7, 1831, of the monthly series of this Journal, that he is in error.

Erinensis.—We have no taste for personalities. The Dublin College of Surgeons are like other men. "To err is human, to forgive divine."

The report of the case of hydrophobia in St. Thomas's Hospital in our next. It reached us too late for this number.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London
Session 1832—1833.*

LECTURE XCV., DELIVERED APRIL 25, 1833.

GENTLEMEN,—In noticing the surgical diseases of particular regions of the body, I must not forget to bring under your consideration *scrofulous caries of the spine*. Perhaps, however, I may not be altogether justified in calling this affection a caries of the vertebræ, because it is alleged that one variety of it begins, not with a morbid alteration of the cancellous structure of any of those bones, but with ulceration of the intervertebral substance. But as the disease, in whatever texture it begins, soon leads to caries of the spine, I think the name sufficiently appropriate. By adding the epithet *scrofulous*, we also distinguish this caries from other kinds of caries, necroses, and simple absorption of parts of the vertebral column; not usually productive of any paralytic affection of the lower extremities.

In whatever manner the disease, which I now mean to speak of, commences, if it be not checked in its progress, it occasions a destruction of the bodies of the vertebræ and intervertebral substance, leaving, as Mr. Brodie correctly says, the posterior parts of the vertebræ unaffected by it; the necessary consequence of which is an incurvation of the spine forward, and a projection of the spinous processes posteriorly. The same pathologist adverts also to the frequent and early complication of the disease with chronic inflammation of the membranes of the spinal cord, and even of the latter organ itself, which, in consequence of the curvature, and, as I have reason to believe, still oftener in consequence of the disease around the spine, quite independently of the mechanical effect of the curvature itself, becomes disqualified for the performance of its highly important function. This observa-

tion is founded on the fact of many cases being upon record, in which the most surprising degrees of curvature, from destruction of the bodies of the vertebræ, were not accompanied by paralysis.

Here, gentlemen, I show you a preparation illustrating the earliest change perceptible in the most common form of the disease, that which begins in the bones. You see in the cancellous structure of the cervical vertebræ, small cells are formed, in consequence of the removal of a portion of the natural texture.

I have already explained to you some of the circumstances described by Mr. Brodie, whose pathological observations on this subject are the best with which I am acquainted. In addition to the information which I have given you on his authority, you should be apprised that suppuration sometimes, and especially in the scrofulous cases beginning in the bones, occurs at a very early period of the disease, and, in other examples, not until a very late stage of it.

Gentlemen, I have in a former lecture endeavoured to give you some idea of the changes in the shape of the spine produced by rickets; there the curvature is lateral, and the spine is twisted, not from any carious affection of the vertebræ, but from their being only imperfectly developed, and not calculated to resist the preponderating influence of the muscles, and weight of the parts which the column has to sustain. However great such ricketty curvature and deformity may be, no paralysis is induced. I have also made you acquainted with that kind of absorption of the bones, which arises from the pressure of aneurism, and other tumours upon them, and which has peculiarities marking it very completely as a different affection from what is denominated caries; for in no situation does it lead to the formation of abscesses; and, in the spine, it is particularly remarked by all pathologists, that it does not give rise to paralysis. When we were on the subject of aneurism, I exhibited to you a specimen of aortic aneurism, which had occasioned such an absorption of the lateral part of the spine, that the medulla spinalis was exposed; yet even in that case, I believe, there was no paralytic affection of the

lower limbs. It is conceivable, however, that the mischief might have gone on till palsy had been excited by its effects upon the medulla spinalis; and I have certainly read of a case, or two, in which the pressure of an aneurismal tumour in the abdomen was the cause of paralysis. Such an occurrence, however, is at all events exceedingly rare.

The greater number of individuals, afflicted with scrofulous caries of the spine, are infants or children; yet many adults also suffer from it, especially after having been weakened by fever, or a long mercurial course. I have not seen any case, in which it began beyond the age of forty-five.

It may be asked, how are we to distinguish scrofulous cases, commencing in the bodies of the vertebræ, from others, which begin in the intervertebral substance? Now, the only information that I can deliver in reply to this question is a remark made by Mr. Brodie, that where the disease is of a scrofulous origin, affecting the cancellous structure, he suspects that it is more immediately followed by suppuration, than where it commences in the intervertebral cartilages; and that, in the latter cases, the pain and tenderness in the carious part of the spine are more considerable than in scrofulous examples.

Gentlemen, let us next consider the general symptoms of caries of the spine. In the early stage, the patient will have pain and tenderness in that portion of the spine which is the seat of disease; and, as I have stated, perhaps these symptoms will be most strongly manifested in those cases, in which the disease begins in the intervertebral substance. If the patient be old enough to describe his complaints, he will tell you that he is annoyed with a feeling of tightness of the chest, uneasy sensations at the pit of the stomach, a torpid sluggish state of the intestinal canal, perhaps some disturbance in the functions of the urinary bladder, and weakness, aching, numbness, and cramps in the muscles of the lower extremities. Now, it is scarcely necessary for me to say, that very similar symptoms may proceed from other causes; and even some of the information respecting the symptoms now enumerated, as appertaining to the early stage, cannot always be obtained, because the patient may be an infant. Hence, until some inequality or projection becomes perceptible on the spine itself, and until the want of control over the muscles of the lower limbs and the paralysis are more established, the diagnosis is generally obscure. The muscles and parts affected with paralysis, must, of course, be those which derive their nerves from the portion of the medulla spinalis below the seat of the disease. Generally there is impairment of motion and sensibility together; but sometimes one limb will retain more or less sensibility, yet be deprived of the faculty of motion.

In different cases, the symptoms differ considerably. Sometimes there is great pain in

the part affected, sometimes none. In many instances, the paralysis comes on early, and often even before there is any material curvature forwards; but, in some cases, you will see the spinous processes making a considerable angle posteriorly, in consequence of the bend of the spine forwards, and the destruction of the bodies of the diseased vertebræ, yet without any paralysis having taken place. Such a case we have now at the Bloomsbury Dispensary: the patient, a girl 6 or 7 years of age, has had for some time disease of the uppermost dorsal vertebræ, with a great curvature forward, and corresponding angular projection backward; but it was only a few days ago that she began to suffer paralysis, which affects not only the muscles of the lower extremities, but those of the trunk, so that she cannot support herself in a sitting posture. The first blister, which was applied, produced a remarkable diminution of the paralytic affection, enabling the child already to sit up, though she cannot walk. The true cause of most of the symptoms is a morbid state of the spine and parts connected with it, attended with irritation and disease, and perhaps sometimes compression of the medulla spinalis itself. The morbid state of the spine, gentlemen, which I am now calling your attention to, always precedes the deformity observable in the vertebral column itself. Indeed, the curvature forward, in such a degree as to produce the angular projection of the spinous processes posteriorly, cannot happen until the bodies of the diseased vertebræ have been seriously injured by caries. The deformity is of a peculiar kind, and such as nothing can produce, except the destruction of one or more of the corpora vertebrarum, the spine being bent forwards, as I have already explained, so as to form an angle backwards. In the preparation before us, you see an example of the kind of deformity, resulting from scrofulous disease of the vertebræ. The bodies of two, namely, the sixth and seventh dorsal vertebræ, are completely absorbed, permitting those below and above the deficiency to join, and be united by ankylosis. The spinous processes are also soldered together. In this case, you may observe, that the sides of the thorax are pressed downwards and backwards, so as to lessen, in a very serious manner, the dimensions of the hypochondriac region. You may likewise remark, that the bones are large and well developed, which is very different from what is noticed in rickets. In curvatures from other causes, there is not an angular projection of the spinous processes; but the bend forms the segment of a circle, generally affecting a great extent of the spine, and often assuming the lateral inclination or spiral figure, with a very conspicuous leaning above towards the right side.

In most cases of scrofulous spine, paralysis of the lower extremities, and even more extensive paralysis, will come on sooner or later; but, in rickets, where the spine may be said to

be deformed rather from an imperfect development of the bones than from disease of them, palsy of the legs is not produced, however great the lateral or spiral curvature of the back. Professor Cruveilhier, in the 4th Livraison of his *Anatomie Pathologique*, gives us the particulars of a case, which proves how very far even scrofulous disease of the vertebræ will sometimes advance without causing paralysis, though this is a deviation from what is most common. In Cruveilhier's case, no paraplegia existed, though not less than five of the bodies of the dorsal vertebræ had been totally annihilated, and the alteration in the shape of the vertebral column was such, that the upper half formed with the lower an extremely acute angle, which would have been still more acute, if it had not been prevented by the eleventh and fifth actually touching one another. The intervertebral foramina were all preserved, though more or less deformed, contracted, or displaced backwards. In those which were most diminished, the corresponding intercostal nerves must have been compressed, and consequently the action of the intercostal muscles impaired, explaining partly the cause of the asthmatic disorder with which the patient was troubled. The engraving, which I now show you, will enable you to understand how nature contrived to maintain the integrity of the vertebral canal, and to keep the spinal cord from being compressed in the midst of such a surprising deviation of the vertebral column from its natural configuration. Although the bodies of five vertebræ were demolished, anchylosis took place, and the medulla suffered no pressure or irritation adequate to paralyse the lower extremities. A beautiful specimen, illustrative, I think, of an equally extensive destruction of the bodies of the vertebræ, and of as sudden a bend of the spine, will attract your attention when you go into the museum of this University. Cruveilhier also gives the particulars of a child, ten years old, brought to the dissecting room, in which only a few vestiges of the bodies of the third, fourth, fifth, sixth, seventh, eighth, ninth, tenth, and eleventh dorsal vertebræ were left. According to this pathologist, diseases of the vertebral column, like those of every other part of the osseous system, are seated, not in the osseous tissue itself, but in the cellular or medullary tissue occupying its interstices. When this cellular tissue inflames, sometimes it pours out pus in abundance constituting an abscess, but sometimes in a more scanty quantity so as to admit of absorption. The cells of the osseous tissue, being distended by the development of the cellular tissue, and deprived of the materials of nutrition, may be entirely absorbed; and thus Cruveilhier accounts for the total disappearance of the texture of bone, without a vestige of it being left. You are probably aware, gentlemen, that Cruveilhier's doctrine is, that all disease is seated in the cellular tissue of organs, the other tissues being, ac-

cording to his views, only liable to simple atrophy or hypertrophy.

Gentlemen, the observations which I have delivered must have apprised you, that the removal of the deformity of the spine, even when you succeed in curing the disease, must be altogether impracticable. There must always remain an angular projection backward, which will be greater or less, according to the part of the spine affected, and the extent of the destruction of the bodies of the vertebræ.

Notwithstanding what I have said, you are not to conclude that every bend of the spine forward is from scrofulous disease. We have the authority of Mr. Brodie for the observation, that a curvature of the spine in this direction may arise from other causes, as a weak condition of the muscles, or a ricketty affection of the bones. Generally, he says, in such cases, the curvature occupies the whole spine, which assumes the form of a segment of a circle. Occasionally, however, the bend occupies only a portion of the spine, usually that composed of the superior lumbar and inferior dorsal vertebræ, the curvature being always gradual, not angular, a circumstance in which it particularly differs from the curvature resulting from caries.

One common effect of scrofulous caries of the spine, is the production of an abscess around the diseased bone. Yet, it frequently happens, that the caries will go on to a vast extent, and even so as to demolish the bodies of several vertebræ, without any abscess being produced. Disease of the spine may continue for years without suppuration; and abscesses sometimes lie upon the diseased bone, but are not detected till after death, when the body is examined.

As I have in a former lecture noticed scrofulous disease of the upper cervical vertebræ, and of the articulations between the atlas and the condyles of the os occipitis, it is unnecessary to repeat the subject; but I may remind you of an observation made by Mr. Brodie, which is, that the pain is greater in such cases than in others, where the disease is in the dorsal or lumbar vertebræ. When abscesses form from disease of the cervical vertebræ, the matter generally collects amongst the muscles of the neck, or behind the pharynx, into which it may pass. As the disease advances, the arms become paralytic, and this while the muscles, which derive their influence from the spinal cord below the neck, remain under the control of the will. Afterwards, however, the paralysis extends to the muscles of the trunk and lower extremities. These, and many other important facts, you will find recorded in Mr. Brodie's work.

Gentlemen, the most approved plan of treating scrofulous caries of the spine consists in employing, in the early stage, cupping or leeches over the part, followed by the application of blisters, caustic issues, a seton, or the moxa. With the local abstraction of blood, you would of course join other mild antiphlo-

gistic remedies, especially aperient medicines, composed of rhubarb and the carbonate of soda, castor oil, or the sulphate of magnesia. After beginning with these means, counter-irritation, or issues, setons, a perpetual blister, or the moxa, may be tried; and these remedies may be assisted with the medicines and regimen usually recommended for other scrofulous diseases, particularly bark, chalybeates, and iodine, with the benefit of a light nutritious diet, and pure country air if it can be conveniently had. One thing is quite essential, namely, the diseased spine should be kept as quiet as possible, and therefore the patient ought to remain very much in the recumbent position. When the disease has existed a considerable time, and a conspicuous angular curvature is formed, I think Mr. Brodie's advice should be followed, which is, to let the patient recline on his side instead of on his back; or if this posture be disagreeable, he should not lie on an absolutely flat surface, but be supported with pillows, so that his position may have no tendency to restore the spine to its original figure, which would only have the pernicious effect of disturbing the completion of the anchylosis, by which alone the cure can be accomplished.

Of late years, issues and blisters, from having been employed in these cases for immoderate periods of time, and without discrimination, have become objects of abuse by certain practitioners. Yet, that they frequently produce great benefit, I am convinced by repeated experience. The little girl at the Bloomsbury Dispensary, a few days ago, with disease and great angular projection of the uppermost dorsal vertebrae, I have told you, became free from paralysis of the trunk a day or two after a blister had been applied. At the same time I am of opinion with Mr. Brodie, that issues are chiefly useful in the early stage of the disease with the view of preventing suppuration, and that they are of no service after an abscess has actually formed. He likewise suspects that issues are of little or no service where scrofulous disease of the cancellous texture precedes ulceration of the cartilages. If this be true, we see, then, the reason why so many cases are not benefited by this plan; but it is a point for further investigation, and one on which I cannot say, that my experience agrees with what has now been suggested.

Besides the carious spine, the medulla and its coverings are liable to chronic inflammation and its effects, as a consequence of external violence. Cases are likewise sometimes met with where scrofulous tubercles form in the medulla itself. Any of these changes may of course impair the functions of this important organ, and bring on paralytic affections. The treatment must be regulated by principles applicable to diseases of joints, and comprise very much the same means which have been advised for scrofulous disease of the bodies of the vertebrae; local bleeding, counter-irritation, quietude in the recumbent position, and

medicines and regimen for the improvement of the health in general.

The next disease, gentlemen, claiming your attention is *Spina bifida*, *hydro-rachitis*, or the *cloven spine*, which is a congenital malformation, consisting in a deficiency of one or more of the spinous processes and arches of the vertebrae, which, indeed, are sometimes deficient throughout the whole extent of the vertebral column.

Now, gentlemen, in consequence of the deficiency of the back part of the spinal canal, the theca vertebralis protrudes, and forms a kind of pouch filled with a limpid fluid. The swelling is of different sizes in different cases, according to the extent of the malformation in the bones, and the age of the individual. The most common situation of it is on the lumbar vertebrae; but it may take place on the dorsal or cervical ones, and even over the sacrum. In some cases an aperture is left in the bodies of the vertebrae, in addition to the absence of the spinous processes. All the processes are occasionally deficient, and the vertebrae small, and not properly developed. The swelling is soft, and attended with fluctuation, and sometimes a degree of transparency. It generally subsides when compressed, but returns as soon as the pressure is removed. The skin retains its natural colour, and there is no pain in the part, unless it be compressed.

Children born with *spina bifida* seldom live more than a year. They are generally weakly and emaciated; and very often afflicted with paralysis of the lower limbs, and of the sphincters of the bladder and rectum. However, I have seen some children with *spina bifida*, who had a healthy appearance and suffered no paralytic complaints. In particular, I remember such a child under Mr. Maul, of Southampton. Sometimes, also, instead of dying in infancy, they live to the adult age, as was the case with a young woman whom I saw some years ago under the care of Mr. Copeland Hutchison, and an engraving of whom I now show you. The urine and feces passed involuntarily. The tumour was of such enormous size that it measured in the vertical diameter thirty inches.

With very few exceptions *spina bifida* proves fatal, and this in the greater number of instances within the first year from the period of birth. Some children thrive for a few years, and appear to suffer little or no inconvenience; but no sooner does the tumour burst, or is it punctured, than convulsions usually come on, and the little patient suddenly dies. This was the final result of the case in which I saw a little boy about two years old, that was in perfectly good health, and with the free use of his legs, though he had a *spina bifida* on the sacrum nearly as large as his head.

Gentle pressure on the tumour was suggested as worthy of trial by the late Mr. Abernethy, with the view of producing an absorption of the fluid, and, if that object could not be accomplished, he deemed the experiment of letting out the fluid by a small puncture,

and then closing the opening with sticking plaster, quite warranted by the commonly fatal course of the disease. This was done in one example, the puncture being repeated every fourth day for six weeks, and regularly healed; but at length one of the punctures failed to unite, the sac inflamed, pus was formed, and the result was fatal.

Sir Astley Cooper tried the effect of puncturing spinæ bifidæ with a fine needle. In one case the fluid was discharged, and the cavity obliterated by the adhesive inflammation, so as to produce a radical cure. This gentleman, however, besides the radical treatment, if it can be so called, as it is only supported by one or two instances of success, has a palliative method, which consists in treating the protrusion on the principle of a hernia, and applying a compress and bandage to it.

Spina bifida when joined with hydrocephalus, paralysis of the lower extremities, and involuntary discharge of the urine and feces, is entirely a hopeless case.

The same observation applies to examples in which the spinal cord itself is deficient.

In many children, the bodies of the vertebrae are not perfectly developed, the ossification of the cranium is not complete, and the disease is associated with other deformities, such as club feet. All these circumstances were illustrated in the case from which this preparation was taken. The child lived only three days.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XXV.

Great variety in the symptoms of Encephalitis—General Conclusions as to the Contraction and Paralysis—Case of Convulsions after the removal of Pressure—Symptomatic Oedema—General Cerebritis—Sympathetic Affections, General and Local—Enteritis simulating Local Cerebritis—Prognosis in Cerebritis—Neuralgic Pains a Symptom.

GENTLEMEN,—To-day we again take up the subject of encephalitis, and allow me here to observe on the extraordinary variety and complication of the symptoms of this disease. Unless you study with extreme care a great number of separate cases of cerebral disease, you will never be able to get clear ideas on the nature of this affection, so peculiarly interesting to the pathologist, and the practical physician. More circumstances seem to combine in creating a variety in the symptoms of cerebral affections, than in those of any other viscus of the body. We have in the case of cerebral disease all the variety of symptoms depending on the peculiarity of the part engaged, on the complication of local encephalitis with arachnitis, on the results of pressure, the nature and extent of effusions, the difficulty created by the phenomena of neurosis, and many other circumstances.

At my two last lectures, I drew your attention to some cases of local encephalitis, in which the disease was pointed out by certain affections of the muscular and generative systems. There are several other circumstances connected with this part of the subject, which are also deserving of attention, and it is necessary that you should be aware that there are other sources of diagnosis in cases of local encephalitis besides those already mentioned. There is no doubt, that though, in many cases, the occurrence of contraction, spasms, and pain in the extremities, precedes that of paralysis, yet we may have paralysis from local cerebritis coming on *without these precursory signs*, and as suddenly as in cases of apoplectic effusion. This important fact you must never lose sight of.

Of this I have now seen several instances. I recollect a remarkable case of a man who had been bled in the cold stage of an ague, with the effect of stopping the intermittent. In a few days symptoms of pneumonia set in with great prostration of strength. These were followed by signs of disease of the brain, which were that the patient became suddenly nearly insensible, and on that day was observed to have his hand constantly placed on the right side of the head. Next day, without any preceding spasms or contractions being observed, he was found paralytic of the left upper and lower extremities, with paralysis of the left sterno-mastoid and loss of sight in the left eye. On dissection we found softening of the two anterior thirds of the right hemisphere, which were of the consistence of thick cream. The disease engaged the corpus striatum, but the optic thalamus was healthy.

Another remarkable instance occurred lately in a person labouring under aneurism of the innominata and hemiplegia. Here the paralysis came on suddenly, and its cause was found to be an abscess of the brain. I must observe, however, that there were some precursory signs in this case, though contraction and spasms were not observed. The patient had violent headach, and was subject for some time to occasional numbness and pain in the affected arm.

I repeat it, you may have the greatest variety in the succession and combinations of the symptoms of this disease, and this observation applies to the lesions of muscular motion, sensation, the state of the intelligence, and the organic functions. You must study numerous cases to get an accurate idea of this disease. I would advise you to examine the writings of Lallemand, Bouillaud, Abercrombie, and Serres on this subject, and then consult the last edition of Andral's Clinique Medicale, where you will find the value of the symptoms discussed in a most impartial and philosophical manner. In this splendid work

you will find many cases of *cerebritis*, in which the symptom of spasm and alternate flexions and extensions was wanting. Indeed he looks upon it as a symptom which cannot yet be called pathognomonic.

We may, I think, come to the following conclusions on this subject:—

1st. That local encephalitis is often accompanied by various forms of muscular contraction in the parts afterwards to be paralysed.

2nd. That in some cases the paralysis is not preceded by muscular contraction, though various lesions of sensibility may occur.

3rd. That the paralysis may be gradual (which is the most common case), or sudden.

4th. That the contractions may be intermittent, periods more or less elapsing, when the symptom is absent.

5th. That in general the contractions occur in the first, the paralysis in the second stage.

6th. That in a few cases the reverse occurs.

7th. That in some cases, general or partial convulsions, and in others, tetanic symptoms, precede the paralysis.

You will see in the *Gazette Medicale*, for October 1833, the particulars of a most interesting case, recorded by Berard, jun., of fungous tumour of the *dura mater*, which was not accompanied by any alteration of muscular motion. This was removed, with the adhering portion of the *dura mater*, when the patient was attacked, for the first time, with loss of consciousness and convulsions of the trunk and extremities. The operator, justly concluding that the sudden removal of the partial resistance of the brain was the cause of the symptoms, applied a piece of agaric to the denuded surface, and made gentle pressure upon it, when he found that immediately the convulsions ceased, and the intelligence was restored. Thus, gentlemen, does disease often become a second nature, and its want is the cause of symptoms.

As far as we see of the brain, this pathological fact appears certain, that injuries of the upper part of that organ are accompanied by more marked and distressing symptoms, than similar lesions of the lower part. There seems, indeed, to be a decided difference between the sensibility of the superior and inferior parts of the brain. The great proportion of those cases, in which there was extensive latent disease of the brain, have been cases in which disease predominated in or towards the inferior surface of that organ. In this situation it has been proved by numerous examples, that you may have extensive disease without those symptoms of muscular or mental derangement, which ordinarily characterise inflammatory affections of the brain. I recollect the case of a patient who was brought into our wards complaining of feverish symptoms, with pain of the left temple, extending to the eye of the same side. With the exception of this pain, he had no cerebral symptoms of any kind; his intellect was sound, and he was quite free from muscular pain, rigidity,

spasms, or paralysis. He was ordered to take some opening medicine, and to have leeches applied over the seat of the pain, but derived no benefit whatever from their application. This led me to suspect that something unusual was going on, and more particularly when I observed that the leeches were repeated without any decided benefit. One morning, on going into the ward, I looked about for him for some time to no purpose; in fact, his countenance was so altered that I could no longer recognise him. During the night, the globe of the eye was almost suddenly thrust forward by an enormous *œdema* of the soft parts of the orbit, and the pain became excruciating. It was then conceived that the pain, complained of on admission, was the result of disease of the bones of the orbit, and that abscess had formed behind the eyeball. Under this impression, and in accordance with the earnest request of the poor sufferer, it was determined to make an incision to give exit to the confined pus. A curved bistoury was cautiously though deeply introduced over the eyeball, but on withdrawing it, only a small quantity of serum escaped. The swelling went on increasing, and the eyeball was pushed forward so as to be raised above the level of the nose. A curved bistoury was then carried extensively round the orbit but without giving exit to any matter. Under these circumstances, I came to the conclusion that it was an example of deep-seated abscess of the brain, with symptomatic *œdema* of the orbit. This *œdema* of superficial parts, in cases of deep-seated disease, is, you know, a thing of common occurrence, and may be observed in many instances of hepatic abscess, acute pleuritis, and other inflammations. In fact, there is such a remarkable sympathy between deep-seated parts and the integuments over them, that you may have this *œdema* in deep-seated inflammation of any organ. The patient now became gradually worse, his agony was intolerable, and the protrusion continued undiminished, but he had not either delirium or convulsions. He sank into a state of profound coma, in which he remained for about twenty-four hours, when death put a period to his sufferings. On dissection there was no pus found in the orbit, and its bones were healthy, but in the inferior part of the anterior lobe of the brain there was an abscess, about the size of a large walnut, resting on the cerebral surface of the orbit. I have since learned from several of my friends, that they have witnessed cases of the same description. It is an interesting disease, and one which you should be acquainted with. I think the existence of the following symptoms should lead you to suspect it. First, pain in the head, preceding the appearance of a tumour of the orbit, and this pain not affecting the orbit itself; for observe, in this case the pain was referred to the temple and not to the orbit. The next thing, is the pain resisting ordinary treatment, and being followed by a sudden

œdema of the parts within the orbit and protrusion of the eyeball. These two circumstances, when occurring in conjunction, should, I think, lead you to suspect acute internal disease. Again, in those cases where abscess supervenes on caries of the internal table of the bones of the cranium, the affection is much more chronic than in this or similar instances of deep-seated abscess of the brain. With respect to this remarkable symptom of local inflammation of the brain, this external œdema, I shall relate the history of another case, as I am anxious to throw as much light as possible on this obscure subject. It may appear strange, that when a dense bony plate and an extremely strong membrane (besides other parts) intervene between the integuments and the seat of disease, that local œdema of external parts should take place as a consequence of internal inflammation. Strange, however, as it appears, it is true, and the intervention of the skull does not prevent it, as will be seen by the following case.

A boy was admitted into the Meath Hospital, complaining of severe pain in the situation of the mastoid process. He was of a scrofulous habit, and had for a length of time a discharge of matter from both ears, with slight loss of hearing. Some time before his admission the discharge had been very copious, but on being exposed to cold it was diminished in quantity, and he immediately was attacked with severe pain behind one of his ears. When he came into the hospital he was screaming with agony, but had no delirium, and the muscular system was unaffected. But what was chiefly remarkable in this case was, that, on the second day after admission, a distinct tumour formed in the upper portion of the neck, about an inch and a half behind the mastoid process. So distinct, indeed, was it, that it was generally believed that the disease was periostitis of the base of the skull, which had run on to suppuration. An incision was made over the tumour, and the knife was carried down to the bone, but no matter could be discovered. The patient became gradually worse, the pain was dreadful, but there were no convulsions. Shortly before death he had a few slight muscular twitches, with delirium, and died in great agony. During the whole course of the disease, the discharge from the ear had continued and was remarkable for its foetor. On examining the brain, we found neither abscess nor arachnitis. On slitting up the longitudinal sinus, a remarkably foetid odour was perceived, which increased as the incision was prolonged in the direction of the left lateral sinus. Here there was a quantity of extremely foetid matter, of an almost cheesy consistence, and mixed with blood, and a communication was discovered between it and the internal ear, the bones of which were carious, and its cavity filled with the same kind of pus. Here we have a curious example of œdema of the external parts depending on deep-seated disease.

I shall now relate the particulars of a case in which, although the symptoms of an affection of the brain were better marked than in the foregoing, still they were by no means so decided as one would have expected from the appearances revealed by dissection. A patient was brought into the Meath Hospital, with symptoms which were thought to be those which mark the ordinary form of delirium tremens. The man had been a great drunkard, but for some time back had given up the use of ardent spirits. He complained of severe and constant pain of the ear, which he stated to be of twelve weeks' standing, and that it was this which first induced him to give up drinking, as he found that it was always aggravated by the use of spirits. On admission, he appeared to labour under a highly excited state of the nervous system; he had general tremors, and was incapable of keeping up a connected conversation, though he could answer a few questions accurately. Here we observe a remarkable difference between this and the last case detailed, in which there was not the slightest evidence of any lesion of the intellectual powers. In the present case, the symptoms were pain, tremors, and incapability of supporting a rational conversation, but no decided constitutional symptoms. The pain, which had never abated since its commencement, became now violently exacerbated, he moaned frequently, and kept his hand constantly applied to the affected side of the head. To this last symptom I beg leave to direct your attention, as it is an exceedingly common one in cases of local inflammation of the brain. After a few days the mouth was drawn slightly towards the affected side, and it was found that the tongue was protruded in the opposite direction. Symptoms of fatuity now became more distinct, followed by coma, and the patient sank. During the whole course of the disease he had no spasms or paralysis of any of the limbs. On dissection there was a circumscribed abscess found in the substance of the middle lobe of the brain. The abscess itself was encysted, but the substance of the brain round it was soft, particularly at its inferior part, where it was found to be connected with a carious state of the squamous portion of the temporal bone. There was a considerable degree of softening in that part of the brain which lay between the abscess and the corpus striatum. Here we have a case in which pain of the ear is chiefly complained of; but, in addition to this, it was observed that the patient could not sustain a connected conversation, that there was some fatuity, that the mouth was drawn to one side, and that coma came on before death. Under such circumstances there could be less hesitation in pronouncing the disease to be an affection of the brain; and accordingly we find, on dissection, unequivocal marks of disease of the middle lobe, in addition to the caries of the temporal bone.

I might detail many cases of a similar kind, without being under any apprehension that I

should be occupying your time to no purpose, for the recital of such cases is better calculated to convey information on this obscure subject than any lecture. I shall, however, content myself with one or two more. A man, addicted to the use of ardent spirits, was brought into the surgical wards of the Meath Hospital in a state bordering on coma. It was thought at first that he was labouring under typhus fever, and, under this impression, no particular attention was paid to the cerebral symptoms for the first day or two. At the end of this period, it was learned that he had fallen in going up stairs, while in a state of intoxication. His head was shaved, but no signs of wound or contusion discovered, though his friends persisted still in their statement that he had fallen while intoxicated and hurt his head. When admitted into my wards he appeared moribund; his pulse was imperceptible at the wrist, he had extreme coldness of the limbs, and a disposition to the formation of gangrenous spots about the ankles. He was in a state of stupor; but when roused answered questions tolerably well, and said that he had no pain in his head. The remarkable feature, however, in this case, was a great degree of muscular rigidity, affecting all the extremities. The fore-arm was flexed, and he had not the power of extending it. The penis was in a state of permanent semi-erection, but there were no seminal emissions. Here was a case in which, taking all circumstances into consideration, the cause of the disease seemed to be in the brain. He had been drunk, and was supposed to have got a fall while in that state; he was comatose, from which, however, he could be roused; and he had rigidity of the limbs, with erection of the penis. With this view I came to the determination of treating it as a case of general inflammation of the substance of the brain. I concluded that there was no arachnitis, from the fact of his answering correctly when roused, while I felt convinced that if there was not actual inflammation of the substance of the brain there was at least very intense and general irritation. The treatment in this case was successful. After warming the extremities by wrapping them in flannel, and the use of artificial heat, the head was shaved, a large number of leeches applied, and an ice cap ordered to be worn constantly. The leeching was repeated, and he used the ice cap for four days. On the second day after this plan of treatment had been entered upon, there was some improvement, but on the following day the accuracy of our diagnosis of inflammation of the brain appeared, for the patient had violent spasms of the right arm and leg. These, however, subsided, the coma, rigidity, and other symptoms also disappeared, and the patient slowly but perfectly recovered. In addition to the means of treatment already detailed, the patient's system was placed under the influence of mercury.

A question might arise as to the exact nature of this case. Was it a case of actual

inflammation of the substance of the brain, or was it mere sympathetic irritation produced by some other disease? It may be said that it was a case of gastro-enteritis, with a sympathetic affection of the head. It certainly might be so, but the great probability is that it was not; because such symptoms as were exhibited in this instance are very rarely the result of gastro-enteritis; and if it was a gastro-enteritis, it is not likely that such complete success should have followed treatment directed to the head. These circumstances make it likely that it was general irritation or inflammation of the substance of the brain itself; and, if so, the case strongly illustrates the utility of mercury, leeching, and cold applications in the reduction of encephalitis. The man was brought into the hospital in a dying state, and recovered under the influence of physiological treatment.

While I am on this part of the subject, namely, the possibility of the head being sympathetically engaged in some instances to a very remarkable degree, I may say that the following conclusions on this point seem to be fairly drawn. That when an affection of this kind depends upon a gastro-enteritis, the signs of cerebral irritation are *general* rather than *local*. In children who are labouring under apparent symptoms of cerebral affection, it has been long known that the irritation of the brain may depend on a variety of causes. In adults, too, the symptoms of cerebral irritation may be the result of various affections, of gastro-enteritis, worms in the intestinal canal, hysteria, hypochondriasis, and many other diseases. In most of these cases, however, particularly with respect to children, the symptoms are general, being pain, delirium, coma, and convulsions on both sides. But we very seldom witness the occurrence of symptoms of local irritation of the brain, as produced by sympathy with some other disease, though it is a fact that they may occur occasionally, and without our being able, after death, to discover any existing local encephalitis. A young female was admitted into one of the surgical wards of the Meath Hospital for some injury of a trivial nature. While in hospital she got feverish symptoms, which were treated with purgatives, consisting of calomel, jalap, and the *black bottle*, a remedy which deserves the name of the *coffin bottle*, perhaps better than the pectoral mixture so liberally dealt out in our dispensaries as a cure for all cases of pulmonary disease. She was violently purged, the symptoms of fever subsided, and she was discharged. A few days afterwards, her mother applied to have her readmitted, and she was brought in again and placed in one of the medical wards. Her state on admission was as follows:—she had fever, pain in the head, violent contraction of the fingers, and alternate contractions and flexions of the wrist and fore-arm. These muscular spasms were so great, that the strongest man could scarcely control the motions of the left fore-arm. In addition

to these symptoms, she had slight thirst, some diarrhoea, *but no abdominal tenderness*. On this occasion a double plan of treatment was pursued, the therapeutic means being directed to the head in consequence of the marked symptoms of local disease of the brain, and to the belly, from the circumstances of abdominal derangement observed in this and in her former illness. She died shortly after with violent spasms of the hand and fore-arm; and as she had presented all the ordinary symptoms of a local inflammation of the opposite side of the brain, we naturally looked there first for the seat of the disease. After a careful examination, however, no perceptible trace of disease could be found in the substance of the brain, which appeared all throughout remarkably healthy. She had all the symptoms which, according to Serres and Foville, would indicate disease of the optic thalamus, or the posterior lobe of the opposite side, yet we could not find any lesion whatever of its substance after the most careful examination. But, on opening the abdomen, we found evident marks of disease; *the lower third of the ileum, for the length of six or eight inches, was one unbroken sheet of recent ulcerations*. This case I look upon as a very singular one, showing that we may have well-marked symptoms of a local irritation of the brain depending on a sympathetic cause. It is fortunate, however, for the study of medicine, that such cases form the exception and not the rule. I may remark here on the latency of the enteritis as to the pain. There was no abdominal tenderness, a fact illustrative of the great law which so particularly applies to gastro-enteric disease, *that when the sympathetic affections are prominent, the usual or local symptoms are proportionally latent*.

With respect to the prognosis in cases of local encephalitis, the following conclusions seem to be well grounded. As a general rule, the prognosis is to be unfavourable, from the nature of the organ, its importance to life, and the frequently complicated and obscure nature of cerebral affections. In local encephalitis you have always two things to apprehend,—the acuteness of the disease and its subsequent effects. The patient may die of acute inflammation, or, if you control this, of the chronic disorganisation which frequently supervenes, terminating in apoplexy, paralysis, and other consequences. On the other hand, it is consolatory to reflect, that experience has proved the possibility of curing both general and local inflammation of the brain. There are numerous cases on record in proof of the success of well-directed treatment. The annals of surgical science are filled with cases of extensive injury of the brain successfully treated; and it is equally true, that medicine can exhibit many instances of well-marked idiopathic inflammation of the brain brought to a favourable termination. In making our prognosis on a case of local encephalitis, much will depend upon the extent to which the muscular

system is affected. Spasm of one extremity is more favourable than spasm of both; and an affection of the muscles of the face is not so unfavourable as of those of the extremities. The next thing to be considered is the age of the patient. In the very young, and in persons advanced in life, our prognosis is not to be so good as in the case of one removed from these extremes, as neither of the former admit of such active treatment; but of the two, it is better to have to manage the disease in a child. It is also singular how well children will often bear active treatment.

There is another point which should not be omitted. There are, in some cases of local inflammations of the brain, muscular contractions and extensions, alternating with a state of rigidity, while in other cases the rigidity is permanent. It is not easy to say which of these cases is the worst, but I believe that the most unfavourable are those in which we have chiefly violent contractions and extensions. Again; with respect to the cessation of the spasms, it may be considered either as a favourable or a most unfavourable symptom. The circumstance of the cessation of the spasms must have been produced by some modification in the state of the cerebral affection. If it be accompanied by a return of the power of transmitting proper motion to the affected limb, it is then a sign of great value, as showing that the cerebral irritation is nearly gone. But if the spasms subside, in consequence of the super-*vention of resolution and paralysis*, then the cessation is a symptom of a most unfavourable kind, as showing that actual disorganisation has taken place, which seems to be incurable.

It may be necessary to remind you that if the patient has, combined with these spasms, alternations of delirium and coma, it affords grounds for making a bad prognosis, as such symptoms indicate that the inflammation has extended to the periphery of the brain, and the arachnoid membrane. The state of the intellect is also a matter of importance; the more intact and undisturbed it is, the greater is the chance that the affection of the brain is confined within a small compass. Here, however, I am anxious to impress this upon your minds, that the absence of delirium should not mislead you, or induce you to form any favourable conclusions on that account alone, in cases of encephalitis, for it is a fact that we may have extensive and fatal disease of the substance of the brain without delirium. I need not tell you that convulsions, or paralysis of one side, do not indicate so unfavourable a prognosis, as where both sides are engaged. Lastly, you should bear in mind that cases of inflammation of the substance of the brain are very subject to relapse. All these circumstances should be taken into account, and a favourable prognosis should be always formed with a great deal of caution.

I alluded in a late lecture to the occurrence of pain in some particular part of the extremities, as a premonitory sign of this disease.

A remarkable case, bearing on this point, has come to my knowledge, and I think I cannot better employ the remaining part of our time, than in giving a brief abstract of it. A lady got a pain in the lower part of the tendo Achillis, which was considered to be rheumatic, and very little notice taken of it. There was no swelling, heat, or tenderness on pressure, in the painful part, and the nature of the disease was so imperfectly understood, that all the efforts of her medical attendants were directed to the heel, but without any benefit whatever. Matters remained in this state for some time, when she was suddenly attacked with convulsions and coma, and died. On opening the head some hours after her demise, a large abscess, together with an apoplectic effusion, was found to exist in the opposite hemisphere of the brain. There are various other examples of a similar kind. I have no doubt that many of those anomalous pains are frequently connected with incipient disease of the brain. I know the case of a gentleman, labouring under a painful affection of the face, which had got the name of *tic douloureux*, and had been subjected to all the variety of treatment which persons labouring under that affection so commonly undergo. But it has since been proved that his complaint is by no means analogous to what has been termed *tic douloureux*, for it has been most successfully treated by shaving the head, and applying leeches and an iced cap over the seat of the suspected irritation. At present, whenever an attack comes on, he immediately gets a bladder, containing a quantity of pounded ice, applies it to his head, and in this way obtains relief. This shows that the severe pain in his case, which many would confound with a local affection of the nerves of the face, is decidedly the result of a morbid sensibility of the cerebro-spinal centre.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS AND CHILDREN,

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE XX.

Rules for the use of Therapeutics in Diseases of Infants—Purgatives—Anodynes and Soothing Syrups—Emetics—Aromatics—Absorbents—Antacids—Saline Medicines—Blisters—Irritants—Mustard Poultices and Fomentations—Antimonial and Stimulating Ointments and Liniments—Blood-Letting—Venesection—Leeching—Cupping—and Dry-Cupping.

GENTLEMEN,—I shall now direct your attention to the precautions necessary in applying our remedial agents to the diseases of

infants and children. It may be laid down as a general proposition, that a very small number of medicines are employed by the most experienced practitioners in the complaints of early life. Sydenham considered that weakness and ascension of the stomach were the predisposing causes of the diseases of infants; and, to correct these, he used two remedies in his practice,—infusion of rhubarb and animal sal volatile. Harris maintained that ascension in the bowels was the cause of almost all infantile complaints, and seldom prescribed any remedy but crabs' eyes. Armstrong held that increased mucous secretion of the intestinal canal was the chief cause of diseases in early life, and preferred *ippecacuanha*. Others, who considered the glandular and secretory systems most commonly affected, introduced mercury. The eastern practitioners were of opinion that theriacs, which consisted of a variety of aromatic medicines, were indispensably necessary to fortify the system. It was only within a short period that a correct pathology and treatment of infantile diseases were determined.

In the year 1777, the French government ordered a small box of medicines, with instructions for their use, to be arranged, and transmitted to the remote parts of the kingdom. This order confided their choice and preparation to M. Lasonne, and their distribution to M. Lenoir. M. Guenet was deputed to prepare a small book on the diseases of infants at the breast, which was inclosed in each little medicine chest. This beneficial order led to the happiest results. The magistrates in the departments superintended the distribution of the works and medicines, and, according to M. Leroy, were the means of preserving more than twenty millions of infants, who would have perished through ignorance or the want of medicines. (*Médecine Maternelle.*)

An order of this kind is unnecessary in this kingdom, as a humane public secures the best medical aid to the poorer classes of society. But in remote parts of the country, where medical advice cannot be always obtained, and where there is a young family, it would be advisable to have a few medicines for domestic use. These should principally be cathartics, and a few others, which I shall mention;—but parents ought never attempt to treat the diseases of their children, unless when medical aid cannot be procured. They never should employ patent medicines, such as Dalby's Carminative, Godfrey's Cordial, soothing syrups for hastening the cutting of the teeth, or quack medicines of any sort. All these are dangerous in the hands of private individuals, are pretended cures for a variety of different diseases, and are not used by educated members of the medical profession, who are unacquainted with their component parts, and consequently would do an act of injustice to their patients and to their own reputation, by substituting unknown for

efficacious remedies. There is no fact better established than that a vast number of delicate children are annually destroyed by the use of narcotics under the title of soothing syrups.

I have already noticed the difficulty of distinguishing their diseases, even by the most experienced practitioners; and hence the danger of parents and nurses attempting to treat them.

Let us now consider the medicines most commonly employed in the treatment of the diseases of children.

Purgatives.—The principal purgatives used for infants and children are manna, castor oil, rhubarb, magnesia, senna leaves (infused), calomel, Epsom and Rochelle salts, jalap, scammony, aloes, camboge, and sometimes elaterium.

New-born infants are generally purged with manna or castor oil; and nurses also use sugar and butter, or what they suppose to be syrup of violets, which is not now kept in the shops. When the mother has breast milk, there is no need of exhibiting aperient medicines to the new-born infant.

A small piece of manna, dissolved in warm milk, or half a teaspoonful of castor oil, is the best aperient for a new-born infant. The French employ a syrup of chicory, the active ingredient of which is rhubarb.

I have already stated that it is impossible to fix the doses of medicines for infants, who differ in vigour and constitution; and the best rule is that we should always exhibit an under dose, and repeat it, if necessary.

As most children are fed with artificial and improper aliments, as pap, gruel, &c., besides the breast, ninety-nine in a hundred of them labour under irritation in the digestive tube,—the stomach and bowels; and, under such condition, purgatives, which aggravate the mischief, must be administered with caution and judgment.

Gastric and intestinal irritation generally exist when an infant suffers from hiccup, griping, flatulency, curdled or green motions, or when it is two, three, or five years of age, and craves for cold drink, picks its nose or lips, and has alvine motions of a dark, green, white, or black colour. When these symptoms are present it would be highly improper to administer senna, jalap, scammony, camboge, or elaterium; manna, castor oil, magnesia, rhubarb, and calomel, combined with aromatic powder, are the best remedies. If the former were administered they would probably induce inflammation, ulceration, or softening of the coats of the stomach and bowels, and most likely destroy life. The antimonial medicines, as the wine of this name, tartarised antimony, or tartar emetic, James's powder, antimonial powder, the oxide of antimony, and the powder or wine of ipecacuanha or hippo, are also contra-indicated and dangerous.

When an infant's motions are unhealthy or depraved during the first year of its life, castor oil, rhubarb and magnesia, rhubarb and calo-

mel, with aromatic powder and loaf sugar, are the best aperients. The doses must depend on the strength of the infant. Let us suppose it is healthful and ordinarily developed for its age: it may be ordered a teaspoonful of castor oil alone, or combined with a drop or two of oil of aniseeds to prevent griping; or three grains of rhubarb, five of calcined or carbonate of magnesia, three of aromatic powder to prevent griping, and ten grains of finely powdered loaf sugar; or the same proportions, omitting the rhubarb or magnesia, and substituting one grain of calomel. Any of these powders is best administered in honey, jelly, treacle, sweetened gruel, arrow-root, or some other thick fluid. The dose may be repeated every four or six hours until it operates. One dose is sufficient in general; and in all cases there is danger that diarrhoea may be induced. Great caution is always necessary on this account.

Calomel is now a favourite purgative for infants, especially with those of the intestinal school, who refer every disease to derangement of the stomach and liver. Dr. Underwood was the first who exhibited it to children. He states, that he never saw it produce bad effects. It has long been observed that this or any preparation of mercury very rarely causes salivation in children, though it has been given to the amount of 180 grains in croup by a very venerable and celebrated Professor, Dr. Hamilton of Edinburgh. Nevertheless, it should not be frequently repeated alone as a purgative in ordinary health, as it renders the body extremely susceptible of the influence of cold, and predisposes to inflammation or congestion of the organs in the head, chest, and abdomen.

It is also to be remembered, that though calomel or other preparations of mercury very rarely induce salivation, even in the largest doses, numerous cases are on record, in which mercury caused ulceration and mortification of the gums and cheeks, which proved fatal. I heard of a case of hydrocephalus in which calomel was continued so long as to cause mortification of the whole of the integuments of the lower jaw, and finally a total separation of this bone from the upper jaw; and what was still as remarkable, the practitioner congratulated himself on the excellence of his treatment! I need scarcely state that the unfortunate infant died a most miserable and deformed object.

Gangrene of the gums or cheek is comparatively of rare occurrence; but it may, for anything we can foresee, happen in any individual case. The late Dr. Clarke had observed salivation in three cases only, under three years of age, and his practice was the most extensive in diseases of women and children.

Calomel is often given to children who refuse other medicines, as it is tasteless, and may be administered in a very small bulk, combined with honey, jelly, or mixed with butter and sugar and spread on bread. When

continued for several days, it renders the evacuations from the bowels of a green colour, and of a slimy appearance. It stimulates the liver and the glands of the bowels, it diminishes the action of the heart and arteries, and supersedes blood-letting in certain cases. (It is, however, a most valuable remedy when given in small doses morning and evening, combined with aperients as above mentioned, in cases in which the alvine evacuations are of a brown or dark colour, and extremely fetid, as we often observe, from the age of one to five years. In such cases the liver is not acting properly, as it is well known that good bile gives the yellow colour to the *stercus*. It may be ordered as follows in such instances, and the quantities increased according to the strength and constitution of the infant: calomel six grains, rhubarb twenty grains, aromatic powder ten grains, sugar thirty grains, to be mixed intimately and divided into six papers or packets, one of which is to be taken morning and evening, unless it acts more than twice on the bowels. When the motions are brown, the *hydrargyrum cum cretâ*, or mercury with chalk, which is a milder and safer preparation than calomel, may be substituted for it in the above prescription. One, two, or three packets will, in most cases, restore the motions to the healthful yellow colour. As there is generally irritation in some part of the mucous lining of the bowels in such cases, the diet should be mild and nutritious, as arrow-root, sago—gravy with either—or mashed potato, &c. ; but solid animal food should be avoided. When these powders are necessary, the infant should be carefully preserved from cold in winter and spring. During the first three months of life, the dose of calomel, as a purgative, is from half a grain to a grain; under the first year, from one to two grains; from the second to the fifth year, from three to four grains; and from the fifth to the seventh year, not more than four or five grains. The dose should be smaller when the constitution is delicate. It should not be given alone as a purgative, and it often acts violently in four or five grain doses even on adults.

The stronger purgatives are sometimes required for new-born infants. These must be administered with the greatest caution; so much as three teaspoonfuls of castor oil, four grains of calomel, and ten of rhubarb, have been given without the desired effect. It is an admirable axiom, that in all diseases we should use the mildest remedies first, and, when these fail, have recourse to the more powerful ones.

Rhubarb has long been a favourite purgative for children. Sydenham first introduced it into vogue, and considered it almost an universal remedy in diseases of infants. In France they make a syrup of the extract of rhubarb and chicory, which is a favourite aperient for new-born infants. Sydenham infused it in water, and ordered it to be administered with wine. M. Leroy imitated his example. Most

practitioners prefer the tincture, though many still employ the infusion and extract. The powder is generally ordered as an aperient for children; and it is usually combined with magnesia, and aromatic powder, or ginger, as already stated. It is a safe and valuable medicine, and often stops diarrhoea when mild. It is also added to saline medicines, such as Epsom salts, and causes it to act mildly and efficiently. Rhubarb has fallen somewhat into disuse of late years, in consequence of its variable effects; but this arises from its being often adulterated with two or three parts of turmeric. Nevertheless, there is scarcely any remedy so generally employed in the treatment of the diseases of children from one to five years old. From the age of three to seven years, the infusion of senna with ginger, sweetened with sugar, and mixed with milk, is given like tea without detection, and is a safe and excellent purgative. A few grains of ginger should be mixed with the senna leaves before infusion, to prevent griping or intestinal irritation. The saline purgatives, such as Epsom salts, Rochelle and Glauber salts, are now very rarely exhibited to children. They are very unpleasant to the taste, and are not better than other aperients. Rochelle salts is sometimes added to veal broth prepared without common salt, and is divested of its taste. Few children could be prevailed upon to take any of the saline remedies. They in general dislike medicines, and therefore we must select those which are most free from taste and odour, and sweeten them whenever we can. There is a great difficulty in getting children to take medicines of any kind, and life is often sacrificed in consequence. If we reason kindly with a child who has any degree of sense, and if we give him some reward, he will show his tongue, take medicine, and even hold out his arm to be bled in some instances. When life is in danger, and persuasion has failed, compulsion is necessary, and this may be effected by closing the nostrils, and holding the hands, inclining the body horizontally, when any medicine placed in the mouth must be swallowed. Parents do not act harshly by having recourse to these means, however disagreeable to their feelings, for the preservation of their children. The temper of children becomes irritable and changed during disease; they are generally peevish, refuse to remain in bed, or to be kept sufficiently warm in the arms of the nurse, by means of a shawl or blanket. They are often seized with inflammation of the lungs, which may be relieved by leeching, &c., but will lay the foundation of consumption or asthma. Few children permit a sufficient examination of their complaints, without their fears and passions being excited, and this arises from the injudicious conduct of parents in threatening them, when they require correction, to send for the doctor to bleed them or give them medicine. Every practitioner will acknowledge that it is of the greatest advantage to administer medicine as

early as possible, as life may be saved by the timely use of an aperient, an anodyne, a warm-bath, or leeches to the head or chest.

Calomel, rhubarb, jalap, scammony, and camboe, are ordered in extreme cases of constipation, when milder means fail, and also in cases of worms or dropsy. The various formulæ will be given under the treatment of the diseases.

Elaeterium is seldom ordered for children; but I have heard of a child under four years of age, who was supposed to be dying of anasarca and ascites after scarlatina, and who was ordered two grains of elaterium in divided doses in five or six hours, which caused twenty watery motions from the bowels, and completely cured the dropsy in the limbs, and abdomen. The practice should be adopted, however, with great caution. Clysters are sometimes necessary, but the cases which require them will be described hereafter.

Anodynes—Narcotics.—Parents and nurses destroy a great number of infants by anodynes, such as laudanum, syrup of white poppy, formerly called diacodium, Godfrey's Cordial, Dalby's Carminative, and various soothing syrups; every one of which should be excluded from the nursery medicine chests when medical advice can be obtained. These remedies are given, however, by almost every mother and nurse to allay pain and produce sleep. All medical practitioners are unanimous in the opinion, that this class of medicines requires the greatest caution and skill in their administration. The mortality of infants caused by anodynes is incalculable. It was immense during the last century in some foundling hospitals, and is still considerable, in consequence of the universal custom among mothers, wet-nurses, and those who have the care of infants, of exhibiting soothing syrups.

"Nothing" says the late Dr. John Clarke, in his Commentaries on the Diseases of Children, "is more uncertain than the effects of opium on young subjects, and it ought never to be employed, even by medical men, except with the greatest caution, as it sometimes acts with much violence, and has proved deleterious even in very small doses. Half a drachm of genuine syrup of white poppies, and in some instances a few drops of Dalby's Carminative, have proved fatal in the course of a very few hours to young infants." The practice of exhibiting anodynes to children is not new. Harris alludes to it two centuries since, and remarks that it swelled the dead, and rid those who had the care of infants of further trouble. Hoffman states that he had seen children labouring under epilepsy and stupor from the use of diacodium and other narcotics. The late Mr. Haden, in his excellent and popular work on the diseases of children, states, that one grain of Dover's powder, which contains but one-tenth of a grain of opium, proved fatal to an infant; and he mentions another case in which one-sixth of a grain caused sleep for two days; he relates a third

case of a child who was destroyed by one drachm of syrup of poppies; and he was called to a fourth case, in which half a drop of laudanum had narcotised a child affected with diarrhoea. He observes, in conclusion, that opium and all narcotics should be prescribed by medical practitioners only. I might quote many other writers in support of this opinion, that the greatest caution and skill are requisite in medical practitioners when prescribing opiates for infants. I shall now state the result of my own observation and experience. My testimony is entirely in attestation of the truth of the preceding statements. The greatest caution, skill, and judgment, are required in prescribing anodynes for infants. I have known a teaspoonful of a mixture composed of one drop of laudanum and an ounce of simple syrup, narcotise a new-born infant. There is scarcely a week in which I have not observed infants under the influence of an over dose of some soothing syrup or other at the Dispensaries which I attend. Mothers usually deny, at first, having used any such remedy, but, when pressed, they confess it with fear and alarm. When an infant is stupified for six, twelve, or twenty-four hours, its breathing becomes laborious, there is a determination of blood to the head, or a predisposition to "water in the head," it cannot awake to take food, absorption goes on, and rapid emaciation, great debility, and death, are the ordinary consequences. It has been long observed by medical practitioners that infants, dosed with anodynes, seldom thrive, are generally feeble, and are usually destroyed by some disease peculiar to them before the fifth year. The digestion is impaired and destroyed by a constant use of narcotics in infants and children, as well as in adults. Those in the habit of taking opium afford ample evidence of the truth of this position.

During the first month of infantile life, a mixture, composed of two tablespoonfuls, that is, an ounce of simple syrup, and two drops of laudanum, or ten drops of syrup of poppies, may be given in the dose of a moderate sized teaspoonful, every two or three hours, until the infant ceases to scream, or falls asleep. In either case the dose should not be repeated for some hours, unless pain or restlessness returns.

I have known cases, in which four drops of syrup of poppies, given to a vigorous infant of five months old with some sugar and milk, induced sleep in less than a minute. About this age, infants suffer more or less from teething, their bowels are disordered, and their sleep is disturbed. These symptoms occur in most cases from errors in diet and physical education, and require the use of anodynes, combined with carminatives. In such instances, the following combination, or one very similar to it, is generally prescribed by obstetricians:—dill water, an ounce; calcined magnesia, a scruple; loaf sugar, three drachms; oil of aniseed, four or six drops;

syrup of white poppies, half a drachm; dose, a teaspoonful three or four times a-day. If this should act as a sedative, and cause sleep, we may substitute two drops of the sedative solution of opium, or four drops of laudanum tincture of opium. The dose may be repeated until relief is obtained, or sleep be produced.

Anodynes are also useful when children are affected with troublesome frequent cough, unattended by wheezing, flushing of the face, and dependent upon irritation in the throat, caused by exposure to cold. In such cases we prescribe mucilage of acacia, or gum arabic, eight drachms; syrup or oxymel of squills, one drachm; compound tincture of opium, or paregoric, half a drachm; sugar, or simple syrup, two drachms and a half; a teaspoonful may be given every hour, until it causes drowsiness, and then it is to be discontinued until this goes away. When the cough is very urgent, we may add one drop of hydrocyanic (prussic) acid to this mixture with advantage, as this is a powerful sedative, and possesses great power in controlling laborious or spasmodic respiration. I have repeatedly added two drops of this acid to the mixture in cases of inflammation of the lungs or their lining membrane (bronchitis) with the happiest results, after leeching, emetics, blistering, and warm bathing had failed. I remember a case to which I was called by my friend Mr. Hughes, of Holborn,—the infant of Mrs. B—, in which we used this quantity of hydrocyanic acid, and ordered a teaspoonful of the mixture containing it every hour, until the breathing was relieved. I have employed this combination in a vast number of similar cases, and also in whooping-cough, with advantage. Great care is necessary to discontinue the medicine as soon as relief is obtained.

Anodynes are also beneficial in diarrhoea of infants. The following mixture is generally efficacious; but there are cases in which more powerful astringents are necessary:—chalk mixture, three ounces; syrup of poppies and aromatic confection, of each one drachm; loaf sugar, two drachms; oil of aniseeds, four or six drops; dose, a teaspoonful, three or four times a-day, or in bad cases, after each motion. In violent cases, in which there are ten, twenty, or thirty motions in one day, it will be necessary to add three drachms of tincture of catechu, and one drachm of extract of logwood to this mixture.

Emetics.—The emetics usually employed in diseases of children are, antimonial wine, ipecacuan or hippo wine, or tartarised antimony (tartar emetic), or powder of ipecacuan in water, in the proportion of one grain to the ounce of water or syrup. These medicines are contra-indicated when there is irritation in the stomach evinced by hiccup or vomiting; and in the bowels, indicated by diarrhoea, black, brown, white, green, or any coloured motions, unless yellow. Antimonial emetics produce most irritation, and may readily induce inflammation, softening, or ulceration

of the stomach, each of which will speedily end in death. Parents, especially among the lower classes of society, are too much in the habit of exhibiting emetics, and often do irreparable mischief. They never should employ them when medical advice can be obtained. Dr. Clarke has known a quarter of a grain of tartarised antimony excite vomiting and death of a child, which was previously in no danger. I have been told of a druggist, whose common fever powder for children is five or seven grains of tartarised antimony; he never weighs it, but guesses at it; and I need scarcely state, that any child who takes this quantity is poisoned, or rather murdered. It is melancholy to think that such ignorant men are allowed to prescribe and destroy human beings with impunity in the greatest nation on earth. Nevertheless, the fact is so.

It is also to be remembered, that, in cases of inflammation of the lungs in children, it is dangerous to urge tartarised antimony in proportionally large doses as in adults, on account of the liability of causing inflammation of the stomach. I shall read to you a letter from a former pupil of mine, who is now in Paris, giving the history of death, caused by repeated doses of tartarised antimony for inflammation of the lung, in a child of three years of age, which was written to me as corroborative of the validity of my opinion. Some late French writers, M. Trousseau, &c., have, however, used the oxide of antimony in cases of adults, with invariable success, in similar cases, while others have as strongly condemned it, as inert and useless. M. Bouillaud observes in his clinical lecture, in April, 1834, “the white oxide of antimony had been fairly tested, it did not produce vomiting or diarrhoea, and its effects were completely null.”—(London Medical and Surgical Journal, No. 119, May 10, 1834, vol. 5, p. 473.)

The older practitioners ordered emetics much oftener than the moderns, and these very seldom employ them at all. The community, however, is still prejudiced in favour of these remedies, and it is therefore very desirable to point out their effects.

Dr. George Armstrong recommended ipecacuanha in almost every disease of children, while others advised antimonial wine as generally—both were in error. Antimonial medicines are still very much employed in diseases of children and adults in this country; and it is the more necessary to inform the young practitioners of their comparative effects when injudiciously administered.

Aromatics.—The aromatics which are most generally used in the treatment of diseases of infants are, oils of aniseed, carraways, cloves, peppermint, aromatic powder, cinnamon, and ginger powders, and aromatic confection. These stimulate the muscular coats of the stomach and bowels, expel flatulency, and, according to the majority of writers, prevent purgatives from causing griping. The aro-

matic powder, ginger, and aromatic confection, are also combined with drastic or powerful purgatives, such as scammony, aloes, camboge, calomel, and claterium, to prevent their griping effects. Some practitioners deny that they possess this power; but if any one of these will take a full dose of any of these medicines, with and without the addition of aromatics, and report that he has suffered equally from griping, I shall freely give up my position.

Aromatics and carminatives are much used in different countries, combined with aliments, drinks, and medicines. The ancient Greeks, according to Sonini, gave them to their children very freely; and, in this country, we use condiments, spices, and aromatics with our food, drink, and medicines. I feel convinced that the milder aromatics ought to be combined with such medicines as require them when prescribed for children.

Absorbents or Antacids.—Harris, who had great experience in the diseases of children, was of opinion that nearly all proceeded from acidity in the stomach and bowels; and he recommended earthy substances, as chalk, magnesia, &c. to neutralise this, and to form a mild aperient. It is well known that a teaspoonful of magnesia and a teaspoonful of lemon, or, in some cases, of orange juice, will form a neutral compound which will act as an aperient on many delicate persons who suffer from acidity of the stomach or indigestion. This class of medicines are mere palliatives, unless when other treatment is employed. The principal medicines of this class ordered for children are, calcined magnesia, prepared chalk, chalk rubbed into a powder with mercury (*hydrargyrum cum cretâ*), carbonates of soda and potass saturated with lemon juice or tartaric acid, in the forms of effervescing draughts or soda powders; carbonate of ammonia, &c. Quicksilver or mercury is triturated with chalk into a bluish powder, and, when combined with small doses of rhubarb or aromatic powder, is, in proper doses, one of the most effective and safe medicines when the motions from the bowels are unhealthy, when a child is feverish, picks its nose, is peevish, refuses every kind of food, and desires cold water, or some other cold drink. When these symptoms are present the disease is called infantile remittent fever, worm fever, fever from teeth, and “water in the head,” by most mothers. The abdomen is enlarged, and the mesenteric glands are often affected.

Under such circumstances, we generally succeed, in a few days, in removing the fever, and restoring the motions to a yellow, healthful colour, by the combination just mentioned. The disease is caused by improper diet or by dentition. It is caused by improper diet, because most families allow their children, from one to five years of age, to dine at the same table with themselves, and partake of the same food, which is injurious, for the following reasons:—Children are gluttons;

they never masticate animal food sufficiently, whether they have teeth or not; they bolt their food, the gastric fluid in the stomach cannot soften or chymify it, the consequence is, that it passes partially changed into the first portion of the bowel (duodenum), the bile is now mixed with it, but does not dissolve all of it or reduce it into chyle; it irritates the surface of the bowel, and the lacteals or absorbent vessels which pass to the glands in the mesentery, and on to the thoracic duct which conveys the chyle or nutriment to the heart to be mixed with the blood; as the repetition of food renews the irritation in the lining membrane of the stomach and intestines, in the lacteal and mesenteric glands; irritation, inflammation, or ulceration of the bowels is the result, attended by fever; or the mesenteric glands enlarge, obstruct the passage of the chyle to the heart, and general emaciation follows. Parents are surprised at the voracious appetites of children labouring under mesenteric disease, and at the emaciated appearance of their limbs and body, while the abdomen is swollen. The explanation is this,—nature demands food, but this is not conveyed through the mesenteric glands to the heart, a new supply of blood is cut off, the absorbents of every part are in action, and every part, except the mesenteric glands, which are composed of absorbents, emaciates. The emaciation is extreme before death, the features shrink, the eyes become prominent, and the visage either resembles that of old age or assumes an unearthly appearance. This has led the vulgar to imagine that their children had been “overlooked, bewitched, or replaced by some supernatural being, or by the diseased offspring of others.” The real nature of the disease in such cases is irritation, inflammation, or ulceration of a greater or less portion of the mucous or lining coat of the intestines, a disordered secretion of liver, and hence the depraved motions from the bowels. The best remedies are the *hydrargyrum c. cretâ*, or calomel in very small doses, combined with rhubarb, compound powder of chalk with opium, continued for ten or fifteen days successively, and then the judicious use of iodine both internally and externally will remove the enlargement of the mesenteric glands, as many of you can attest from ocular proof at the Dispensaries which we attend together. The dose of the *hydrargyrum c. cretâ* for an infant under a year old, is one or two grains combined with rhubarb, as already stated, night and morning. No medicine restores the bowels to a healthful state sooner than this, unless when the evacuations are black, and then calomel should be substituted for it in the preceding prescription.

Calcareous medicines, as lime-water, the solution of the muriate of lime, &c., have been long exhibited in enlargements of the lymphatic system or glands, as in scrofula, rickets, &c. and these are now replaced by iodine and its preparations, which, when genuine and judi-

ciously administered, are astonishingly efficacious in every form of scrofula. The most ample attestations of the truth of this statement are daily afforded at St. John's Hospital and the Western Dispensary.

Saline Medicines.—The carbonate of soda, saturated with lemon-juice or tartaric acid, and sweetened, has successfully cured two children affected with purpura, after every other remedy had been tried at two public Institutions in vain. I believe the neutral salts have great influence on the blood, though I cannot assent to the theory of Dr. Stevens.

Mr. Cameron, a naval surgeon, in his work on Diet, lays claim to the priority of discovery as to the effects of saline medicines on the blood, and states that his patients who had been deprived of vegetables, who had become pale, and threatened with scurvy, acquired a florid or high complexion by the use of nitrate of potass or common nitre. I need scarcely observe that the neutral salts have been used in febrile and many other complaints from time immemorial. The world, however, is indebted to Sir Gilbert Blane, Bart., for the discovery of an effectual cure for sea-scurvy, to which purpura is so nearly allied. In cases of children predisposed to the latter disease, the use of ripe subacid fruits will be beneficial; but, in general, these should be sparingly allowed on account of the predisposition to ascendency, according to some, or irritation of the stomach and bowels, in the opinion of others, in early life.

Blisters and Irritants.—I have stated on a former occasion that the skin of young infants, and even of children, is extremely irritable, and liable to be inflamed by the slightest external injury. A slight burn on the finger of a child may cause convulsions and death in a few hours. The bite of an insect—a gnat for example—on a young infant may excite inflammation in a few minutes, and therefore we cannot be surprised that the irritation of a blister, a mustard fomentation or poultice, the antimonial ointment, or powerfully stimulating liniments, may rapidly induce violent inflammation in infants, and this has often been followed by mortification, sloughing, and death. The experienced part of the profession never allow a blister to remain on a young infant, or a child under five years of age, longer than three or four hours; in fact, they order it to be removed as soon as the skin is reddened. It is quite unnecessary to allow the blister to rise, as it is popularly termed. If any of the blistering plaster remains on the skin it should be always washed off with tepid water. I cannot agree with a recent writer on diseases of children, who advises the reddened and tender part to be covered with new flannel, to prevent the child taking cold. The irritation which would be produced by such a plan would be intolerable; and I cannot but express my surprise at such a recommendation. Some writers advise that a piece of fine muslin should be placed under the blister to prevent

the absorption of the flies, and the strangury or pain in evacuating the urine which follows it. Others order powdered camphor to be sprinkled on the surface of the blister for the same purpose. Whenever a blister is applied to children, some mucilage of acacia or gum arabic—for example a quarter of a pint—ought to be mixed with the drink. I have repeatedly seen mortification, sloughing, and ulceration caused by blisters on different parts on children, when left applied for twenty-four hours, which is, unfortunately, the usual period.

Blisters have long appeared to me to be too slow in their action; and that inflammation in the head, chest, or abdomen, might prove fatal, before they produced the desired effect. The object of a blister is to cause local or counter-irritation; and this can be done in a minute or two by rubbing the skin with warm oil of turpentine. When the skin is reddened by this remedy, it should be discontinued, as it would produce intense pain, but this can always be very speedily abated or removed by the constant application of cold water for a few minutes. The superior advantage of this remedy is, that its effect is sudden, and it does not induce strangury or painful micturition. In my own practice I have for six years ceased to order blisters, for the reasons I have assigned. My learned and experienced friend, Dr. Copland, was the first to advise the application of turpentine, as a substitute for blistering, in the former series of the London Medical and Surgical Journal, the London Medical Repository, of which he was the editor. There is also a valuable paper in the Dublin Journal of Medical and Chemical Science, for March 1834, by Dr. Little, of Belfast, on the value of the application of warm turpentine in diseases of the lungs, hooping-cough, asthma, bronchitis, pulmonary consumption, &c., and in croup.

Mustard Poultices and Fomentations.—These are often applied to the feet and legs in cases of inflammation of the brain, lungs, or abdominal viscera, and should always be removed so soon as they excite pain. I have known a mustard fomentation excite pain in a child of two years of age in less than a minute, and if continued might induce convulsions, or be followed by its usual consequences when applied too long, inflammation, ulceration, or gangrene. I have known several cases of adults, in which mustard poultices were applied for twenty-four hours, when the patients were supposed to be dying, convalescence occurred, and also most painful ulceration of both legs as high as the calves.

I witnessed a case of typhus, in which mustard poultices were left on for thirty hours as the man's life was despaired of. He, however, convalesced; both legs mortified, and it was necessary to amputate both below the knees. Another case was that of a gentleman, who was attacked with erysipelatous inflammation of the scalp and delirium tremens. It was supposed by three physicians, who were also practical surgeons, that effusion into

the brain had taken place, and under this impression, mustard poultices were applied to his feet and legs. He was declared to be moribund; when I exhibited his habitual stimulus, he convalesced and recovered. There are two similar cases of erysipelatous inflammation of the scalp, related by Sir Astley Cooper in his lectures on surgery, which were considered mortal, and which were cured by gin after the usual remedies failed. The mustard applications did not redden the skin. In six weeks after his convalescence, both his legs ulcerated, and he was confined to his sofa for three months before the ulcers had healed. There is also caution required in using hartshorn and oil, and other stimulating liniments.

The antimonial, or tartar emetic ointment, is sometimes employed in diseases of children, but great caution is necessary as to its use. It causes an eruption of pustules, like small-pox, which are very painful. This remedy should never be applied over an ulcerated or blistered surface, as it excites a degree of pain which few can bear. This ointment should rarely be applied to children.

The medicines I have named are sufficient for the infantile medicine with the addition of hartshorn or sal volatile, and olive oil. Anything else required may be had from the druggist.

Blood-letting—Leeches—Cupping—Dry-cupping.—The best rule that can be laid down on the abstraction of blood by bleeding from the arm, or opening the temporal artery or jugular vein, is to be guided by the effect produced, and not by the quantity of blood which is taken. It is an axiom that we should make a free orifice, which allows the blood to flow rapidly, gives the system a sudden shock, causes fainting, or an approach to that condition which is desirable whenever venesection is necessary, and does all the good that can be expected, at the least loss of the vital fluid. It is known to most practitioners that the removal of six or eight ounces of blood from a large orifice will cause fainting, while the abstraction of ten times the quantity, from a small orifice, will not produce the same effect. It appears to me that the safest and best precept with regard to blood-letting is, to make a large orifice, and allow the blood to flow until the countenance changes, giddiness, or loss of vision is complained of, and then cease. As constitutions differ, there can be no fixed rule, I imagine, as to the quantity of blood to be taken. The directions now given by the most scientific and experienced practitioners are, bleed from a free orifice to the approach of fainting. There are some of the old school who order twenty or thirty ounces of blood to be drawn, a vein is freely opened, eight or ten ounces are abstracted, the patient faints, and the operator binds up his arm. I am disposed to think that most of you have repeatedly acted in this manner.

Venesection cannot be easily practised on young infants, on account of the smallness of

their veins, but its necessity is efficiently obviated by leeches. New-born infants, when properly fed and preserved from the influence of cold, very seldom require leeches, unless when attacked with purulent ophthalmia. A leech to each eyelid will be sometimes required in this desperate disease, though a single leech, applied to the chest in cases of catarrh or bronchitis, will afford the most decided relief. It is to be recollected that the skin is extremely vascular and irritable, and that the loss of blood from one leech-bite has frequently destroyed life. When the bleeding is excessive, the countenance becomes pale, the eye glassy, the forehead and extremities cold, the respiration difficult, and should fainting occur, it will be almost impossible to rouse animation or to preserve life. The usual means of arresting the bleeding are, the application of cold water, vinegar and water, agaric, compression, cauterisation with caustic or a wire heated to redness. Leeches should be applied over a bony surface, so that efficient pressure may be made to stop the bleeding if necessary. It is wrong to leave any discretionary power to nurses, the practitioner should not leave until he has arrested the bleeding, as infants and children have frequently sunk from exhaustion; and there is at all times the greatest difficulty in restoring them. It is now generally agreed that leeches cause a determination of blood to the part on which they are applied, and also that in congestion of the brain they should be placed behind the ears, along the jugular veins, or to the neck near the roots of the hair, and not on the forehead, temples, or crown of the head, as is usually done.

Cupping.—This operation is rarely performed on children, on account of the vascularity and sensibility of the skin, though it has lately (1834) been very strongly recommended by Dr. Burne, at the Medical Society of London. He stated that he had repeatedly ordered it for children of all ages with the best success. It appeared to me to be pregnant with danger in cases of very young infants, and extremely likely to induce convulsions, or congestion of the brain or lungs by the violent screaming which I should think it would excite. I have not tried it, and therefore cannot speak from experience; but very extensive observation enables me to state, that dry cupping has superseded the necessity of general and local bleeding in my practice in most of the diseases of children; and it is a remedy, even in cases of adults, which will generally supersede local bleeding in a great number of instances. It possesses this great advantage, that it requires no scarification, no loss of blood, and that we may apply as many glasses as the extent of surface over the affected part will admit. In cases of infantile diseases it is invaluable.

Dr. Blundell has arranged a table of the quantity of blood that may be taken at the following ages; but I cannot help thinking, that any fixed quantities are as objectionable as attempting to determine the exact doses of

medicines. If constitutions were alike, and children of the same age equally vigorous and well developed, then we might go by fixed rules; but until then I should be guided by the effect produced, and not by the quantity abstracted. You will of course adopt whichever plan you think most reasonable and best.

During the first month an ounce may be taken; from the second to the fourth month, two ounces; from the fourth to the eighth month, from two to three ounces; from the eighth to the twelfth month, from three to four ounces; from the twelfth to the eighteenth month, from four to five ounces; from the second to the third year, from eight to ten ounces; and from the sixth year to the eighth, from eight to twelve ounces. These were the quantities as set forth in Dr. Blundell's Lectures, in the *Lancet* for 1826; but it appears by Dr. Castle's edition of the *Principles and Practice of Obstetrics*, &c., by Dr. Blundell, just published, p. 832, "What quantity may be safely drawn at once must be determined by circumstances; but the following tabular statement of quantities of blood, which I have taken away myself at different ages, may perhaps be of some service as a guide:—

From a child of	oz. aver.
2 months old from	1 to 1½
4 months old —	1½ to 2
8 months old —	2 to 3
12 months old —	3 to 4
18 months old —	4 to 5
3 years old —	8 to 10
6 years old —	10 to 12

The quantities in this table are the same as in the former account, unless that in the latter there is no mention made of the quantity for an infant of one month old.

Notwithstanding the authority of the justly celebrated obstetrician just quoted, for whom, in common with the cultivators of medical science in this and all countries, I entertain the highest respect, I feel bound to inform you that I act on the precept already mentioned—bleed from a free orifice, and be guided by the effect produced, and not by the quantity taken.

When it is necessary to open a vein in children, a ligature is applied round the wrist or instep, the limb immersed in a basin of warm water for the purpose of congesting the part and rendering the veins more apparent. In all cases of children I would advise you to watch the countenance, and if you see it becoming pale or collapsed, as already described, stop the flow of blood, whether from a vein, by leeching, or cupping, should you employ this last operation.

At our next meeting, gentlemen, I shall commence with *Pædonosology*, or a Description of the Pathology and Treatment of Diseases of Infants and Children.

Foreign Medicine.

The inefficacy of Chlorine in Phthisis Pulmonalis.

BY A. TOULMOUCHE, D.M.

(From *Archives Générales de Médecine*.)

THE paper written by M. A. Toulmouche on this subject is divided into two distinct parts,—one in which he points out the inefficacy of the employment of chlorine in phthisis, the other in which he proposes to show the efficacy of this medicine in chronic pulmonary catarrh. The first contains remarks on seven cases, all of which were characteristic of confirmed pulmonary disease, and the patients died, after having been submitted to the treatment of chlorine for a longer or shorter period. It will be unnecessary to dwell on this part, as most practitioners are aware of the inefficacy of this remedy, as well as all others that have been attempted in this affection. Nevertheless, as there are some medical men who still believe that the non-success of medicaments, especially that of which we are speaking, arises from their mode of use, we will enter in a short account of the method adopted by M. Toulmouche.

In the first case of which he speaks, the chlorine was commenced about two years after the premonitory symptoms of this disease, and continued for fifty days; in the second, at the termination of a few months, and continued for sixty days; in the third, at the termination of three months, and employed for fifteen days; in the fourth, five months, and continued for forty days; in the fifth, at the end of four months, and used for four days; in the sixth, after the tenth day, and employed for fifteen days; finally, in the seventh, commenced a few days after a relapse, and continued for fourteen days.

The author states that he would have annexed a much greater number of observations, if he had not been fearful of making it irksome to the reader; for, with the same unsuccessful, in his particular practice, he has experimented on more than sixty phthisical patients, and on nearly twenty others at the Penitentiary in the west.

A pretended case of phthisis, that he believed to have cured by the employment of the chlorine, made him suspect that if he con-

stantly failed in this affection, he was able to succeed by its use in chronic pulmonary catarrh: he therefore prescribed it in these cases, and its use has since been crowned with the greatest success.

Case.—M. D., aged 36, tall and thin, of a very irritable, nervous temperament, had always enjoyed good health, in spite of all kind of bodily indulgences. A constitutional syphilis supervened at the time of his marriage; moral inquietude followed, his general health soon became affected, cough with mucous expectoration, and profuse perspiration supervened. I examined him carefully (he states), and immediately opposite the superior spinatus fossa of the right side, and supposed there was pectoriloquy, but this was uncertain. A blister was applied, sea air was recommended, without an amelioration of the symptoms; in fact, emaciation and feebleness continued to increase.

On the 27th of October I commenced the inhalation of chlorine, and it was continued till the termination of the month.

On the 5th of November, the sore throat, which originated from syphilis, and had for a long time existed, looked healthy, and its ulcerated surface diminished, cough became less frequent, and the patient slept well; the profuse nocturnal perspirations diminished, and pains of the chest ceased.

Jan. 20th, 1830.—He returned to his occupations, cough had entirely ceased, and the cure was completed.

Four months afterwards M. D. died from acute gastritis, complicated with cephalitis. At the autopsy, the lungs were discovered healthy, with the exception of a dilatation of the bronchi at the superior and posterior part of the right lung, which easily explained the deception of the resonance of the voice, and made me believe that in that spot there was imperfect pectoriloquy.

M. Toulmouche relates two more analogous cases, and would, he states, have added more, if it was not for the length of his essay, and if he had wished only to point out the utility of the chlorine medication in chronic catarrh.

On the Cure of Fistula Lachrymalis by Perforation of the Superior Maxillary Sinus.

BY M. LAUGIER, SURGEON TO THE HOSPITAL NECKAR.

This new method has been proposed by the reporter for some years, but has remained quite unnoticed till the present day. He has again revived it, and attached to it an importance which at first he had not perceived. In a long account, written by him in the *Archives Générales de Médecine*, he commences by showing how he was induced to propose this artificial opening. He studied on the dry bones of the face, the opening proposed by Woolhouse through the unguis, when he recognised that the partition which separated the maxillary sinus from the nasal canal was also thin and brittle, and that a perforation in this point would be more favourable for the passage of tears. For, in fact, when the os unguis is perforated directly and horizontally, the artificial opening corresponds to the narrowest part of the nasal cavity, and is not in relation with the lachrymal sac, or when the instrument is directed from above downwards, and the oblique course has a few lines of length in the pituitary membrane, the chances are too great for its obliteration by a perforation on the side of the sinus; on the contrary, the opening is always inclined to the lachrymal sac, its course is short, direct, and opens into a large cavity; and, finally, whilst the pituitary is thick, soft, and a little adherent to the unguis, the sinus is lined by an adherent mucus, nearly fibrous, and but slightly disposed to thicken, even in the state of inflammation.

After minute researches, he finds that an opinion so simple and natural has not been premeditated by any author. But in a work by M. Briot, entitled *Sur les Progrès de la Chirurgie Militaire depuis les Guerres de la Revolution*, he finds an observation connected with this subject. M. Briot and M. Picot not being able to find the nasal canal, the latter, in manœuvring to discover the passage, used too much violence with a blunt pointed stylet, fractured the wall of the maxillary sinus; and what at the time was thought a bad accident, became a source of cure for the patient. In the *Traité des Maladies de la Bouche*, by Jourdan, we find the history of a lachrymal

fistula, that opened in the maxillary sinus, followed by cure after the ablation of a molar tooth. But these observations remained useless, even in the hands of their authors, and M. Briot even believed at the time, that the probe had traversed the plate of the orbital fossa.

Convinced of the priority of the discovery, M. Laugier published it in the first instance to replace the operation of Woolhouse, but he has now repropounded it as a general method in substitution of the seton and canula. The following case will show the mode of putting it in practice.

A woman, 72 years of age, was admitted into the Hospital Neckar for fistula lachrymalis of the left side, which she had been troubled with for a long period, and was accompanied by slight inflammation. Leeches and emollient cataplasms were employed without any effect, and the operation was decided upon.

The instruments consisted of an ordinary bistoury, and a small trocar, the body of which was bent, about six lines from its point. The patient was placed as in the ordinary operation, says the author, and the puncture being made, some pus escaped upon the cheek. The bistoury being slightly raised with the left hand, I glided on the blade the body of the trocar, the point below, and the convexity of the line above and within. As soon as it had entered into the superior part of the nasal canal, by raising the handle of the trocar, and turning its convexity towards the root of the nose, I inclined its point towards the external wall of the canal of the nose, and with the greatest facility caused it to penetrate the maxillary sinus. The direction of the instrument left no doubt on this point. In withdrawing it, I turned it from behind forwards, and from before backwards, and upon itself, the body of the trocar grinding, as it were, round this new formed passage. The patient suffered but slightly during the day; the succeeding days a slight quantity of blood and pus were discharged on blowing her nose; the application of emollients were continued on the internal angle of the eye, the swelling gradually decreased, and on the 15th day from the operation, the patient left the hospital completely cured, the nose even had become humid.

M. Jobert at the Hospital St. Louis, has

treated successfully many cases of this obstruction by this method, but the particulars of his cases are faulty. The only objection that we can make to this operation is, that the nasal orifice of the superior maxillary sinus is frequently obliterated, which must be newly perforated in the most inclined part to permit of the operation.

There is another method, also indicated by M. Laugier, of acting on the external wall of the nasal canal, which is by only distorting this wall towards the maxillary sinus; if this comminutive fracture, at all times, without perforation is possible. By this means a considerable widening of the nasal canal is produced, but simple perforation appears to him at present preferable. What is the value of this new operation? In every case it ought certainly to supersede the perforation of the os unguis, and the latter, without doubt, should be abolished from practice. As to its acceptance as an ordinary method, that of course must depend upon difficulties. The canula of M. Dupuytren is so easily placed, so sure in its results, and so rarely accompanied with inconveniences, that it will be an impediment against every rival operation. Nevertheless the method of M. Laugier will have at least this great advantage, if in the course of the operation the surgeon is unable to find or open the nasal canal, it will leave him a very simple resource, and one that appears to us free from inconveniences.

Reviews.

The Liverpool Medical Journal. Published monthly, under the Superintendence of an Association of Physicians and Surgeons, chiefly attached to the Medical Charities of Liverpool.

(Continued from page 605.)

We resume our notice of this new and promising contemporary, and are happy to find it contain so much practical information given by men of experience. The hospital and dispensary reports are very numerous and concise, they remind us of what medical officers of public charities may do in imitation of Scarpa and Sabatier, with their fifteen beds each, if they were disposed to avail themselves of the opportunities they enjoy. Many experienced

practitioners have also enriched the pages of the periodical before us, as will appear by the following communication, which is next in order for our notice.

"Practical Observations on Uterine Hæmorrhage after Delivery, and the means of Prevention. By J. Latham, Surgeon.—I am well aware that the means I am about to recommend so strongly, have been mentioned by some few modern writers on this subject: to originality of thought, therefore, I make no pretensions.

"My sole object here, in coming before my brethren, is to make those means, if possible, more extensively known; and, what is more essential, that they should be more generally adopted, by which, I am quite sure, life would be often spared.

"From an extensive practice in midwifery of upwards of thirty years, few practitioners could have met with a greater number of alarming cases of Uterine Hæmorrhage after delivery than myself. When I reflect on some of the worst of those cases, the deluge of blood has been so great, that I shudder at the thought. Indeed, it has often been a matter of great surprise that life has not been more frequently extinguished; and it appears to me, that this subject has not had the attention paid to it which its importance demands.

"There is an old saying, and a very true one, 'It is better to prevent than to cure,'—which is my principal aim. No doubt the tranquillising plan is desirable for the patient's comfort and safety during labour: and that it is requisite to prohibit the improper use of stimulants; to guard against hot rooms; encouraging the recumbent posture, and keeping the lower extremities warm. If the patient has suffered from hæmorrhage in a former confinement, I would strongly recommend the membranes to be ruptured as soon as practicable, with a view to excite the early contraction of the uterus; and should the pains be violent, threatening hasty delivery, to retard somewhat the expulsion of the head of the child, by moderate pressure on the perinæum.

"I believe it is a common practice, almost immediately after the head of the child is born, to lay hold of it, and, by forcibly pulling it, hurry away the remainder of the body, rather

than to leave it to the efforts of nature to accomplish. This last would be a far more safe and desirable practice, and one by which the fundus uteri would be forced lower down towards the pubes, and, in all probability, would prevent the irregular contraction of that viscus.

"It would be dangerous for a practitioner in midwifery to consider, that all probable cause for anxiety for the safety of his patient was at an end, on the delivery of the child; in fact, it might be correctly said to be then just begun; and we should fall far short of doing our duty by leaving the patient too soon afterwards; for, if any fatal consequences should ensue from hæmorrhage, when blame is attached (particularly to the young practitioner), I am very sure it would do much more harm, as has been often said, than the loss of a dozen by sickness.

"The sooner the better (at all events after the birth of the child), a bandage should be applied, and by placing several folded napkins under it, on the abdomen, immediately over the uterus, a more uniform pressure can be made.

"It will be well here to observe the necessity of making an early examination as to the state of the uterus (particularly when the result of a former labour leads to an expectation of hæmorrhage), and to endeavour without delay to assist its contraction by extending the hands over that viscus, firmly and evenly grasping it—the patient lying on her back. Time and experience have convinced me of the advantage of this means in particular, when persevered in, over every other. Should 'flooding,' notwithstanding, come on, in addition to the above, the usual form of cold applications should be freely used. By these means, I think, there will be little to fear from retention of the placenta within the cavity of the uterus, which is an appalling circumstance, and attended sometimes with danger.

"As my object principally is to urge the necessity of the preventive means, I must again be allowed to say, that by prompt attention, and firm adherence to the above remarks, a complete contraction of the uterus from its fundus will, in all probability, be obtained,—the only safeguard against 'flooding;' and on which the safety of the patient mainly depends.

"I conclude, in full confidence that these remarks will meet the approbation of those professional gentlemen who have, or who have had, an extensive practice in midwifery."

"Wavertree, near Liverpool,

"April, 1834."

The practice recommended by Mr. Latham is exceedingly good so far as it goes; and is what was adopted until a recent period. But in our opinion there is a more efficient mode of managing the class of cases under notice, than the above. When hæmorrhage is expected after delivery, it appears to us, that the ergot of rye is the remedy before the rupture of the membranes, when the labour is natural, the infant's head presenting, the pelvis undeformed, and the os uteri considerably dilated. We cannot assent to the opinion that "should the pains be violent, threatening hasty delivery, to retard somewhat the expulsion of the head of the child, by moderate pressure on the perinæum." It appears to us that if the pains were violent, or, in other words, the uterine action strong, there would be little, if any danger, of after-hæmorrhage. On this principle we should exhibit the ergot of rye to increase the pains, which would also cause the expulsion of the placenta, the contraction of the uterus, and the prevention of hæmorrhage. We might mention many cases, in which this plan prevented hæmorrhage. We fully agree with Mr. Latham that it would be safer to allow the uterus to expel the body, after the head was born, than to pull it away forcibly, an operation which no one but an ignorant obstetrician would be anxious to accomplish. It is evident that if the uterine action was increased by the ergot, and rendered permanent, there would be no necessity for bandaging the abdomen, applying pillows, or grasping the uterus—all excellent proceedings when there were no better. Mr. Latham and ourselves agree in the opinion that a complete contraction of the uterus is "the only safeguard against 'flooding,' and on which the safety of the patient depends;" but we accomplish it by different means. We take leave of that gentleman with every sentiment of respect for the soundness of his opinions, and the excellence of his practical precepts.

The next paper is "On the use of Strychnine in Amaurosis. By Hugh Neil, Surgeon

to the Liverpool Ophthalmic Infirmary."

The author relates some interesting cases of amaurosis, and concludes, "that in no instance have I seen strychnine useful in amaurosis, if internally administered; nor in any have I seen it successfully used when the iris had completely lost its motion."

In many cases detailed, the remedy was effectual, though it did not produce twitchings; in some instances a bitter taste was perceived on the palate, and in others in which the happiest results were anticipated, the writer has been disappointed. We are not surprised at this last declaration, as it is extremely difficult to procure strychnine in a genuine form. Mr. Neil maintains that this medicine may be advantageously used in almost every form of imperfect amaurosis. "I think," says he, "it might also be used with much advantage in many of the atonic diseases of the ear." We fully agree with him in the last opinion, as we have cured many nervous persons of deafness with this remedy.

The last paper, "On Hemiplegia during Pregnancy. By Dr. Roberts, of Rhyl," is worthy of attentive consideration.

"The patient, aged about 40, of rather spare habit, had had several children, but during her preceding pregnancies she had not suffered from any of the accidents to which women in that state are liable, and the course of the present pregnancy had been, up to the last month, equally favourable. About the middle of the last month, while crossing the street, without having complained of any premonitory symptoms, she was observed to fall down in a fit. She was carried home immediately. I was sent for, but did not see her for two hours: at this period she was sitting in a chair, supported by two persons. The power of speech, and of motion on one side of the body, was completely lost: the sensation on the same side was not very perfect. She appeared to be in the complete possession of her senses. On inquiry, I found she never had any similar attack previously, nor any symptom which might indicate a tendency to determination of blood to the brain. Her bowels had been costive. She was bled to approach of syncope. Immediately after the bleeding the power of motion in the affected side was slightly improved, and the patient expressed herself as better. Purgative medi-

cines were ordered, but, from a mistake on the part of the patient's friends, were not given until the following day. At 7 P.M. on the following day I again visited her, accompanied by Mr. Hargreaves, surgeon, of Burnley, where the case occurred. At this period, several pretty free evacuations had been effected. The countenance appeared more lively, and the woman in every other respect appeared improved. The hemiplegia, however, remained. Considering the advanced period of pregnancy, I regret that at this period no examination was made into the state of the neck of the uterus. In an hour after I was sent for to visit the patient in great haste, and in about half an hour found her completely delivered of both child and placenta. The uterus was perfectly contracted, and no flooding had ensued. In the course of a few weeks, by the use of purgatives and mild antiphlogistic treatment, the motion of the side, as well as the power of speech, was restored.

"The favourable termination of this case relieved my mind from a considerable degree of anxiety as to the result. Not being able, on referring to different works on midwifery, to find any similar case to guide my prognosis, I had my doubts whether the paralysis might not extend to the womb, and prevent the expulsion of the child, or the still more important degree of contraction requisite for the prevention of mortal hæmorrhage. In Dr. Cheyne's work on Apoplexy, a case which occurred in the practice of Dr. Kellie, of Leith, is recorded, presenting circumstances very similar to those in the preceding case. The following short abstract is given, with the observations of Dr. Kellie and Dr. Cheyne.

"J. A., aged 32, of spare habits and slender form, married, the mother of two children, in the ninth month of pregnancy, was seized during the day, while washing, with acute pain in the head, giddiness, and disposition to syncope. The pain was momentary, and she continued her occupation. She felt, however, unusually languid and fatigued, and complained of shivering on going to bed. The next morning she was found in a profound sleep, and breathing high. On awakening her, she opened one eye, groaned, and could not speak. Dr. Kellie now visited her, and found her completely paralytic on the right side. She was bled and purged freely. Examina-

tion of the neck of the uterus was made, when no indication of the commencement of labour was found. In the evening, on re-examination, it was found more relaxed than in the morning. On the following morning, she was found much in the same way, having given no indication of pain or suffering. On examining her, however, labour was found nearly effected, and in a few minutes she was delivered of a living child. The placenta was naturally thrown off; the uterus contracted vigorously, and no flooding ensued. The symptoms of the apoplectic seizure, however, grew worse, and she died at six o'clock the following morning.

"On this case, Dr. Kellie observes, 'The ease with which the uterus performed its important functions, in this case of paralysis, is deserving of notice. While the patient was apoplectic, and unconscious of her sufferings, or at least so deprived of the power of voluntary effort and motion as to be unable to express her condition and sufferings by any external signs, the uterus appears, as an involuntary muscle, to have acted in the most perfect manner in expelling the foetus and secundines, and to have afterwards preserved its tonic contraction; so that the flooding which might have been anticipated did not take place after delivery.' The following remark made by Dr. Cheyne on the latter case, I quote as an apology for publishing my own. 'I have nothing to add to the remarks of this accurate and acute observer, but that I do not know a case more worthy of record than this, which I owe to his friendship.'

The next part of our contemporary is devoted to hospital and dispensary reports, some of which are worthy of notice. These we shall place under contribution in our *British Hospital Report* department. We congratulate our Liverpool brethren on the value of their labours, and we trust they will long continue to add to the records of medical science.

The American Cyclopædia of Practical Medicine.

Notwithstanding the fulsome puffing of the monopolists in this metropolis, and their silly declarations before Parliament that they alone stand pre-eminent as the renovators of the medical sciences, they have not as yet ventured, as a body, to arrange any systematic

work, except that miserable one, the *Medico-Chirurgical Transactions*. In other nations, the whole of the distinguished professors associate and produce Dictionaries and Cyclopædias of Medicine, which reflect honour on themselves and the countries to which they belong. Our Gallic brethren have already published eight or ten systematic Dictionaries, consisting of more than a hundred octavo volumes, while we, who in our own conceit are far their superiors, have produced one compilation in four volumes octavo,—the *Cyclopædia of Practical Medicine*. Let us contrast this with the work of our American contemporaries.

The Cyclopædia of Practical Medicine and Surgery, a Digest of Medical Literature.
Edited by ISAAC HAYS, M.D.

The indefatigable editor of this work has long conducted our valued contemporary, the *American Journal of the Medical Sciences*, with great ability and judgment; and his accurate translations of Broussais' *Physiology* applied to Pathology, and other works, are well known to those who cultivate modern medicine. He is assisted in the *Cyclopædia* by most of the medical professors in the United States; and they have undertaken to compress into eight volumes a *complete Library of the Medical Sciences*. They have laid the French Dictionaries, Copland's Dictionary, the *Cyclopædia of Practical Medicine*, and the *Encyclopædisches Wörterbuch der Medicinischen Wissenschaften* under heavy contribution. They inform us that their work will not be like ours, but what it ought to be.

"This work will present a digest of the existing state of knowledge in all the branches of the healing art; in special, regional, abnormal, and general anatomy; in physiology, pathology, therapeutics, materia medica, pharmacy, hygiene, surgery, obstetrics, legal medicine, and medical police. The main object of medicine, the curing and preventing of diseases, and affording relief for injuries, will be kept steadily in view; and the development which each subject will receive, and the mode of treating it will, in a great degree, be determined by its importance in reference to practical medicine. Whatever is truly philosophical in medicine is also useful,

although the application of the science to the art requires much reflection and sound judgment; it is therefore not intended to restrict the term practical medicine, as has sometimes been done, to the mere description of the symptoms of diseases, and an enumeration of the remedies employed in their treatment; such a restriction is derogatory to the dignity of medical science, and degrades it to a gross empiricism."

In this kingdom the profession is wofully disunited,—we have University against University, College of Physicians against College of Physicians, College of Surgeons against its rival, Apothecaries' Company against its namesake,—all contention, strife, and disunion. Nevertheless, if we look to our monographic works, they are admirable; but our conjoint productions are miserable. We cannot comprehend why there should not be a unity of feeling—a national pride, which characterises every Englishman,—a cordial co-operation among the members of a liberal profession, and a display of talent, which, united, would eclipse all other countries. Our motto unfortunately is—*Divide, et impera*.

BASTARDY — INDISCRIMINATE SALE OF CERTAIN MEDICINES.

THE subject of bastardy is connected with some heinous crimes, of which the medical profession is so peculiarly cognizant, that we shall make no apology for offering some remarks on the proposed amendment of the Poor Laws, concerning the maintenance of bastards, and the opposition it has excited.

It has been said that certain anomalies in the law of property to the prejudice of women could only be accounted for by the fact that men were the legislators. How far the observation is also applicable to the laws that regulate or control the intercourse of the sexes, is an extensive and interesting topic.

The universal practice of mankind, founded without doubt upon physiological distinctions, has recognised the right of the male sex to make the overtures of marriage, and has thrown upon the other sex the task of yielding to, or resisting these importunities. From this commerce arises the most odious breach of faith of which a man can be guilty,—the detestable, selfish crime of seduction, for which the law seems to despair of giving the wretched victim any adequate reparation; for the unfortunate woman has no action against her seducer, unless upon the breach of a promise of marriage. Under the fiction of compensating a father or master for the loss of her services, damages may perhaps be recovered; but not one shilling of them can the injured female claim directly. Whether this moral wrong should be left still without redress, civil or criminal, or what are the difficulties the legislature has to encounter in making the guilty violator of chastity amenable to human laws, it would take us far from our immediate purpose to consider. Such, however, as the law is, it is plain it does not reach that lowest class which is the subject of the Poor Laws. Unfortunately, the law really applicable to them has broken down the only effectual safe-guard of female purity; for, whatever may be the defects of the proposed alteration, it cannot be denied that bastardy has increased to a frightful degree under the operation of the existing laws. It is quixotic to expect the sense of honour to be extremely delicate amongst the lower orders; the loss of character is scarcely felt amidst a host of offenders; and the chance of securing a husband under the terrors of the magistrates, with the certainty of procuring an ample provision by a repetition of the offence, are temptations

too great for common frailty. It is idle for persons with little experience of the sadly altered maxims of a pauper population, to apply to its situation the principles that govern a more cultivated order of society. With regard to those who are aware of the difference, we are at a loss to assign a motive for their perversion of the simple truth, or their allusion to the filthy abominations of Carlile in discussing this subject. It is but too true that the present system has disarmed the lower class of females of their natural caution, and has swelled the list of another fruitless source of misery—improvident marriages.

It were vain to expect that any system could abolish the crime of seduction altogether. But if any could accomplish it, that at present in operation has as good a claim to the rare merit as any other, as it has tended to make the female the willing, if not the inviting accomplice of her paramour:—seduction she can seldom allege.

The only plausible objection we have heard raised to the proposal of throwing the burden of an illegitimate child upon the mother, is the apprehension that such a change would lead to more frequent attempts to procure abortion, and perhaps to child murder. The latter crime is seldom attempted under the mere pressure of poverty. It more usually arises from the desire of concealment under a burning sense of shame, and has never been frequent among the lowest orders. Upon this point we are much struck with the following observations, which we extract from a report to the Commissioners published in their report.

“Desertion of children, with infanticide, were objections sometimes urged against the plan. But the great majority of clergymen, magistrates, and others

whom I examined on the subject, thought that the former would not be more frequent than at present, and that abortion and infanticide would be less frequent, not only from there being fewer cases to give rise to them, but because the man who is now the first to suggest these crimes, especially that of abortion, and to assist in their execution, could no longer have an interest in doing so; and the female, left to herself, from maternal feelings and natural timidity, would seldom attempt the destruction of her offspring."—p. 175.

There is much weight in these remarks. At the same time, if any means could be devised for punishing effectually the betrayer of female innocence among the poor, without making the punishment operate as a mere inducement to after-marriage, we should hail the improvement with satisfaction.

We humbly submit to the serious consideration of Mr. Warburton whether some check ought not to be put to the indiscriminate sale of certain medicines, which we will not more particularly name. A little private inquiry will satisfy him of the necessity of adopting this suggestion. In our opinion, every apothecary and druggist should be sworn to keep the medicines we allude to, together with certain poisons, under lock and key, and to suffer none but himself or a sworn assistant to dispense them, upon a proper recipe. Most advisedly do we recommend the adoption of some such course in compliance with the earnest entreaties of many respectable medical practitioners. Knowledge is power. In proportion to our command over medical agents for purposes of health, are the abuses of the same agents for the most guilty purposes. We hope it is sufficient merely to allude to this subject.

CORONERS—THEIR ABOLITION RECOMMENDED.

SIR WILLIAM BLACKSTONE, the great panegyrist of all our legal institutions, affects to lament the decay of the ancient dignity of Coroners, and the mercenary motives that influence persons to seek the office in modern times.

"Now, indeed," observes the celebrated commentator, "through the culpable neglect of gentlemen of property, this office has been suffered to fall into disrepute, and get into low and indigent hands; so that although formerly no Coroners would condescend to be paid for serving their country, and they were, by the statute of Westm. I, expressly forbidden to take a reward, under pain of great forfeiture to the king, yet for many years past they have only desired to be chosen for the sake of their perquisites, being allowed fees for their attendance by the statute of 3 Hen. VII. c. 1, which Sir Edward Coke complains of heavily, though since his time those fees have been much enlarged."

Of the offices at the present day recognised in the constitution, and whereof we may trace the duration to a very remote period, that of Coroner retains some of its earliest features unaltered by the lapse of time; a circumstance to be attributed, perhaps, to the little attention paid by the legislature to the duties attached to it. The sheriff has long ceased to be elected by the freeholders. The Coroner is still chosen by popular election, notwithstanding the total change of times and manners. Were an officer to be now-a-days for the first time appointed to superintend the serious inquiries into the causes of death, which by mere accident form the principal business of Coroners in modern times, no

person would dream of throwing the responsibility of a fitting choice upon the freeholders of a county, or even upon the constituents of a reformed House of Commons. The appointment would be vested either in the ministers of the crown or in some local body, by which the abilities and qualifications of the candidates might be somewhat better estimated than by the crowd of a hustings. The election of a Coroner is attended with great expense, as great, it may be, as that of a Member of Parliament. The candidate is generally some ambitious attorney, who seeks the office for professional notoriety. His ignorance of medicine (to use the word in an enlarged sense) he pretends not to conceal. The election is almost invariably the consequence of party intrigue, with this additional curse, that few but the least educated and most prejudiced of the electors will take any interest in the result. Instead, therefore, of being pleased with an attempt at present in progress to regulate the election of Coroners upon the principles of the constituency of the Reform Bill, we should have considered it a subject well worthy of the attention of the legislature, to inquire whether the office of Coroner in its present form should not be abolished, and whether in its stead a properly qualified officer should not be appointed by some responsible authority for presiding over inquests. We trust the medical committee will take up this important subject, and point out to parliament the very unsatisfactory manner in which all medical investigations are conducted upon inquests, in consequence, as we contend, of the ignorance and incompetence of Coroners and their juries.

We understand, that by the laws of France information must be given to the police of every death that happens, and

that an inspection and inquiry take place, which of course, if there be any suspicious circumstances, lead to a full investigation, resembling our inquests in its outward form, but in no other respects; for the one is as much characterised by patient inquiry and scientific research, as the other by slovenly ignorance.

Our laws have made no such jealous provision for the safety of life. The Coroner is called into action by a very ancient statute of the date of Edward I., which was passed with reference to the troubled state of society at that age, when the violence of hostile and armed men was no uncommon occurrence. The language of this statute will show the real nature of the evil, and the object of the institution.

“The Coroner, when certified, shall go to the place where any is *slain, suddenly dead, or wounded*, and command four, five, or six of the next towns to appear before him at a certain place, and, by their oaths, inquire if they know where the person was *slain*, whether in a house, field, bed, tavern, or company, who guilty, or who present, men or women, and of what age; whether slain in the field or wood, where found or brought thither, and how, on horse or cart, if known or a stranger, and where he lodged last.” And if the guilty party be found, the Coroner is to “go to his house and inquire what goods or what lands he hath, and of what value, and when valued deliver them to the township, who shall answer for all;” for the property of the criminal was usually forfeited to the king. One peculiarity of the Coroner’s jurisdiction deserves to be noticed, that the inquest must be held “upon the sight of the body,” *super visum corporis*; so that if the body be not found the Coroner cannot sit.

In the preceding remarks, we have confined ourselves to the special duties of the Coroner at the present day, which we think might be transferred with advantage to other hands.

His remaining judicial duties,—of inquiry after shipwrecks and treasure trove, or persons likely to have found treasure—who, according to the statute, “live riotously and haunt taverns,”—are, we apprehend, not very troublesome nor serviceable.

We shall conclude our observations by a brief statement of the Act of Parliament concerning Coroners to which we have alluded. It has passed the House of Commons, and has been read a first time in the House of Lords. It has been much altered already in its progress, and is likely to undergo further modification before it becomes law; so that it were useless to print it at large in its present imperfect shape.

The Act provides that counties shall be divided into districts, to which the present Coroners are to be respectively assigned. And that upon the death or removal of the Coroner of a district, the parliamentary electors resident within the district shall elect a new Coroner for that district. Thus the election is placed upon the basis of the Reform Bill, and, by the division into districts, some portion of the expense and inconvenience occasioned by a county election is removed. The polling is to continue for two days only. Of course the candidates are to bear the expenses of the sheriff in providing for the election.

It is proposed to increase the fees of the Coroner upon inquisitions, in places chargeable with county rates, to thirty shillings instead of twenty shillings, and to one shilling and sixpence for every mile he has to travel in his district,—the

fee at present is nine-pence. The following is the clause introduced by amendment into the act during its progress in the House of Commons for the remuneration of medical practitioners.

“And whereas at the taking of inquisitions on the bodies of persons lying dead, it is frequently necessary for the more satisfactory explanation of the cause of the death of such persons that a *post mortem* examination of such bodies, or of some parts thereof, should be made by some surgeon or other person of the medical profession, and his evidence given on such examination: and whereas there is at present no remuneration provided for such surgeon or other person, whereby great difficulty exists in procuring such *post mortem* examination to be made: be it therefore enacted, that in every case where the assistance of any such surgeon or other person for the purpose of such *post mortem* examination, and his evidence thereon, shall be thought necessary and required by the coroner and jury, the constable of the parish or place shall, on the direction of the coroner, pay to every such person, if he shall require it, a reasonable fee (*such fee in no case to exceed the sum of one pound*) before he shall be called upon to give his evidence. Provided always, that such remuneration shall not be given to any such person where he shall be called upon only to give evidence as the medical attendant of such deceased person during his lifetime, or at the time of his death.”

We need scarcely call the attention of our readers to the paltry fee, the *greatest* a medical practitioner is entitled to when his skill and time are required to investigate the physical causes of a mysterious death. No respectable practitioner could of course afford, in justice to himself, to attend an inquiry of the kind. The busi-

ness must be left to be jobbed by some underling, unless, to the honour of the profession, there be no one found to accept the pitiful remuneration, and the legislature be compelled to devise some other means for securing a *post mortem* examination.

It is intended to declare the Coroner's Court an open court; and, in order to secure a better jury than usually assembles before him, the coroner is to be empowered to inflict a fine of forty shillings on such as are summoned and refuse to attend.

To the coroner, to the jury, to the medical remuneration, to the whole system, we have an insuperable objection.

PARLIAMENTARY COMMITTEE ON MEDICAL EDUCATION.

DURING the last few days deputies from the Scotch and Irish medical corporations have been examined by the Parliamentary Committee, and the worthy Chairman elicited a vast deal of information, highly beneficial to the great cause of medical reform. There can be little doubt but the laws relating to the medical profession will be entirely changed during the next session of Parliament. It is rumoured that there will be three new acts for England, Ireland, and Scotland, or one including the whole of the United Kingdom.

Foreign Hospital Reports.

HÔTEL DIEU.

Umbilical Hernia—Strangulation produced by Scirrhus—Contraction of the Small Intestine—Reduction—Continuance of Symptoms—Death.

ELIZABETH FRANCOISE, aged 52, of strong constitution, and sanguineo-lymphatic temperament, has been troubled for twenty years with an umbilical hernia, which has always been worse during the periods of parturition. The hernial tumour was about the size of a pullet's egg; she had never taken any care of it by bandaging, though many times she had suffered from symptoms of strangulation. These symptoms till this period (the 10th of

May last), had always yielded to the ordinary treatment, viz. leeches, baths, cataplasms, and rest, &c.

On the 10th of May she made a false step, and in the effort to save herself from falling, she heard a cracking noise in the umbilical region, and immediately in this part felt acute pain; symptoms of strangulation supervened, such as a sense of weight in the precordial region, nausea, hiccup, and bilious vomiting. She was immediately received into the Hôtel Dieu, and the ordinary means adopted for its reduction. After being in the bath some time, the symptoms became alleviated, but only for a short time.

At 8 o'clock in the evening new symptoms ushered in; the patient evidently became much worse; her bowels had not been relieved since the commencement of the symptoms. A foecal evacuation was obtained after repeated clysters, and she passed a tranquil night.

The remedies for reduction were continued, the tumour became inflamed and painful, and the colicky symptoms increased in intensity; the surface of the body was bedewed with a cold clammy sweat; the eyes became glassy, cheeks were flushed, and the countenance indicated the greatest distress; pulse feeble; abdomen tender, particularly around the umbilical region; great exhaustion. The tumour was elastic, its tegumentary covering remained unchanged. On attempting its reduction, a portion of the contents of the tumour re-entered its natural cavity, but immediately the pressure was removed, the tumour again enlarged.

On the third day reduction apparently had taken place, a small quantity of foecal matter was discharged by the rectum, and all the symptoms decreased in urgency, and M. Dupuytren expressed a hope of the patient's doing well; but on the evening of the 4th all the symptoms again reappeared, and their intensity speedily carried off the patient.

Autopsy.—On examining the body, the parietes of the abdomen were first raised, so as to recognise, if possible, the nature of the strangulation. The portion of the small intestine which formed the hernia, was concealed by the thickness of fat in the abdominal parietes; it was of a brownish red colour for fully two inches in extent, but not in a gangrenous condition. M. Dupuytren at this

period of the autopsy, regretted that he had not performed the operation, when his dresser, M. Feissier, on examining the inferior part of this intestine, found its membranes scirrhous, much thickened, and sufficient to have given rise to all the symptoms that took place, and prevent the passage of alimentary matter to the large intestines.

EGYPTIAN SURGERY.

From a Report by CLOT BRY of Cairo.

High Operation for Stone.

The subject of this operation had several fistulæ in the perinæum, strictures of the urethra, and chronic cystitis. Lithotrity could not be resorted to, and the high operation was determined upon, although considered in itself dangerous. The peritoneum was not wounded, but the bladder was found to be contracted over the stone, and concealed in the pelvis; some difficulty was experienced in opening it, the stone was very friable, and was extracted by means of the curette. The patient died the following day of inflammation of the bladder.

Hydrocele treated by Incision—Tetanus—Cure by Bleeding and large doses of Opium.

A young Greek had hydrocele of the left side, with considerable enlargement of the testicle; incision was had recourse to, and lint was applied in the wound. Inflammatory symptoms; and on the 5th day tetanus supervened, attacking all the muscles of the anterior and posterior part of the limbs. Blood-letting, both general and local, with large doses of opium employed, and the patient recovered.

Tetanus is a very uncommon disease in Egypt, although it attacked the French soldiers very frequently during the expedition. This would lead one to suppose that strangers are more subject to it than the inhabitants of the country.

Empyema of both Sides of the Chest successively—Cure.

A young Arab had for some time complained of pains in the thorax, difficulty of respiration, sleeplessness, and a sense of suffocation. On examination, the left side of the chest was found to have acquired considerable

development, the ribs were widely separated from each other, and the intercostal muscles stretched; fluctuation was ascertained; the tumour was punctured, and several pints of purulent serum, containing flocculi of coagulable lymph, discharged through the opening, which was kept free for several days, and perfect recovery ensued. A month after, the right side, which was healthy at the time of the first operation, presented exactly the same appearances, requiring the same operation, which was followed by a similar result.

British Hospital Reports.

ST. THOMAS'S HOSPITAL.

Hydrophobia.

DURING the present week, another case of this distressing disease was sent by Dr. Roots from the neighbourhood of the Foundling Hospital to this institution. It occurred in a woman, 72 years of age, who six weeks previously to her admission was bitten by a favourite cat. The animal had been unwell for three or four days, and the people to whom it belonged were about giving it some castor oil, which irritated it, and while enraged it darted at the old woman, and bit her in the left hand, about an inch above the wrist, and between the tendons of the extensor primi and secundi internodii pollicis muscles; an hour after which the animal was destroyed. Whether it had bitten any other individuals or not we have not been able to ascertain. The wound soon cicatrised, during which progress no particular pain was experienced, and the woman enjoyed perfect health, though previous to this she had suffered from rheumatism. On Sunday last, six weeks from the accident, she complained to her friends of experiencing acute pains, which commenced with a tingling sensation about the fingers, and extended up to the shoulder, quite different from the rheumatic, which she had so frequently experienced; this symptom continued the whole day. Early on Monday morning she complained of heaviness about the chest, with difficulty of respiration, which continued to increase, and soon was accompanied with slight spasmodic contraction of the gullet. The assistant of a medical man now saw her, and found her labouring under difficulty of respiration, and spasm of the throat. He prescribed some volatile spirit, but could not make up his mind as to the nature of the affection. The symptoms continued to increase, and it was not until the next evening, when Mr. Dalton, who saw the patient, heard anything to throw light upon the disease. They now related to him the circumstances about the cat: the symptoms were spasm of the respiratory muscles, copious spitting of

viscid mucus, spasm increased by even the slightest attempt to swallow liquids; and he believed it to be a case of feline rabies. About eleven o'clock at night he called upon Dr. Roots, whom he requested to visit the sufferer. Dr. R. immediately accompanied Mr. Dalton, to see her, and after taking into consideration the circumstance of the bite, together with the symptoms, agreed with the latter gentlemen as to the nature of the disease. She was at once, by the request of Dr. Roots, sent into this hospital, where she arrived about one o'clock in the morning. At the time of her admission there was wildness, accompanied with great anxiety of countenance, face pallid, eyes sunk in their sockets, pupils dilated; violent spasmodic contractions of the muscles of respiration, particularly of the diaphragm and oesophagus, which by even hearing of the sound or seeing liquids were much aggravated. All polished objects produced the same effect, and the attempt to swallow any fluid was unsuccessful; skin clammy and cold; pulse 84, intermitting and feeble. Complained of a burning heat about the head; was free from pain, and quite rational. Not much flow of saliva, but she made perpetual efforts to hawk up the small quantity secreted. The sound thus made was very peculiar from the great oppression she was labouring under in her efforts to excrete the viscid mucus; and has been said by many writers to resemble the yelping or barking of a dog. Tongue covered with a yellowish mucus: feels thirsty, and asked for some water, which when brought to her, she begged to have removed instantly. By the direction of Dr. Roots, 40 minims of the liquor plumbi subacetatis were administered on a lump of sugar, and were to be repeated every two hours, unless symptoms supervened to contraindicate their use.

The symptoms continued during the night; at times she talked incoherently, but upon being spoken to she always was rational. No alleviation appeared to be produced, and she complained several times of extreme pain in the head, and heat about the fauces and palate. Medicines continued.

Nine o'clock, A.M.—Spasms somewhat relieved; more tenacious mucus secreted; the constriction or choking sensation continues, immediately before which she endeavours to hawk up and spit out this vitiated secretion. Thirst excessive; asked for some tea, which she now drank without aggravation of the spasm; pulse 74, small and feeble; skin cold and clammy.

At eight o'clock, by her own request, some more tea was given, which she drank without aggravating the spasm. Appears much exhausted; great distress of countenance; eyes haggard and glassy, pupils in a state of fixed dilatation. Continues rational; still the same wild aspect of countenance; pulse 84.

Ten o'clock, A.M.—Spasms not aggravated by liquid; drank some cold water with apparent ease; with this exception all the symptoms remain the same.

Half past one, P.M.—Spasm now appears chiefly confined to the diaphragm; some rigidity of the muscles of the larynx; respiration 12 in a minute, each respiratory effort is combined with spasm; pulse not perceptible; cold and clamminess of the skin; hands and feet blue. Suddenly, whilst being raised, she was seized with a violent spasm, which checked, for a time, the respiratory efforts; gasping followed, and great prostration ensued. After remaining in this state for the space of ten minutes, the vital powers again appeared reinvigorated. During this death-like interval, no pulse could be felt at the wrist; wine was administered by teaspoonsful, which she swallowed without much aggravation of symptoms. From the exhausted condition of the patient, and the feebleness of the circulation, some wine and ten grains of the oxymuriate of potash every hour were prescribed.

The potash being dissolved in water, was administered by teaspoonsful; spasm not increased; pulse countless. One of her relations now stood at the bedside, but she did not recognise him, although about two hours previously she knew her niece who spoke to her. There has been from the commencement great rigidity of the recti muscles, from their contraction; urine since her admission passed involuntarily; bowels open once; alvine dejection extremely foetid; excessive prostration.

Three o'clock, P.M.—Another dose of the potash has been given; respiration scarcely perceptible; spasm much decreased in violence, but increased in frequency; pulse languid, scarcely perceptible; eyes remain fixed. Without apparent violence of the spasm she suddenly expired.

During the whole of the 18th, the ward in which the unfortunate sufferer lay, was thronged by medical men and students, all of whom appeared perfectly convinced of the nature of the disease.

Autopsy twenty-four hours after death.—The brain and spinal marrow were first examined. There was slight venous congestion, and the arachnoid appeared more vascular than natural: no morbid appearance could be detected in the encephalic substance; spinal marrow healthy, except in one spot between about the 9th and 12th dorsal vertebrae, where it was softer than natural. The corpora striata were said to have been of a darker hue than usual, but if so, the difference indeed was very slight. The thoracic and abdominal cavities were attentively examined, also the oesophagus and larynx, but no morbid alteration could be detected.

There are but few cases on record, in which the disease has permitted the patient to swallow without difficulty, as in the preceding towards the close of the disease. This, however, though unfrequent in the human being, is by no means uncommon in rabid wolves, dogs, or other animals; in the latter species, instances have been recorded in which the animal has drank milk, and swam through a

pieces of water *. Sauvages also says, “ Constat repetitâ apud Gallo-provinciales experientia, canos luposque rabidos bibisse, manducasse, flumen transiose, ut olim Marologii, et bis Forolivii observatum, adeoque nec cibum nec potum aversari.” As to the nature of the affection in the above case, not the slightest doubt can be entertained; we have no positive proof of the cat being in an actual state of rabies, in consequence of its being destroyed immediately after inflicting the wound. It appears pretty well established that this disease is dependent upon some specific virus, yet it must be recollected that most animals, when excited to a high degree of rage, inflict a wound of a much more irritable kind than when in a state of tranquillity; and there are numerous examples in which such wounds have been very difficult of cure, and not a few in which it has proved fatal; as though at all times under such a state of excitement, some peculiar acrimony was secreted with the saliva. In the Ephemera of Natural Curiosities, is an example of symptoms of hydrophobia, produced by the bite of a man worked up in a state of fury†, and in the Leipsic Acta Eruditorum is another instance of the same kind‡, though neither of them seems to have been fatal. Wolff and Zacutus Lusitanus have each an instance of such a bite terminating in death, yet without hydrophobia. Le Chat gives a case of death produced by the bite of an enraged duck; and in a German miscellany of deserved repute, we have another of the same kind§. We could here enumerate several other instances in which death has take place within a few days after the bite of

the enraged animal, but enough has been said to caution our readers against leaving such wounds, however slight they may be, to take their chance, and we cannot too often impress upon them the urgent necessity of immediate incision or cauterisation of the inflicted wound.

BOOKS.

A PRACTICAL Treatise on Medical Jurisprudence, with so much Anatomy, Physiology, and Pathology, and the Practice of Medicine and Surgery, as are essential to be known to Members of Parliament, Lawyers, Coroners, Magistrates, Officers in the Army and Navy, and Private Gentlemen; and all the Laws relating to Medical Practitioners. With Explanatory Plates. By J. CURRY, Esq., Barrister at Law. Part I. Royal 8vo. pp. 466. Twelve Plates. H. Butterworth.

This work is an elaborate treatise on the numerous subjects on which it treats, including all law points connected with them, and evinces the most laborious research, judicious compilation, and legal experience. We shall notice it fully in our next.

Popular Treatise on Chemistry. By HUGO REID, Lecturer on Chemistry to the Glasgow Mechanics' Institution. 12mo. pp. 48. Plates. Glasgow: Rutherglen and Co.

CORRESPONDENTS.

M. Moscati.—We have received a pamphlet and another letter from M. Moscati, neither of which can, agreeably to our consistency, be further noticed by us. The writer has evidently mistaken the meaning of our reply in our last. He is not the only phrenologist in London.

Dr. Slade.—We shall insert the article very shortly.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London
Session 1832—1833.*

LECTURE XCVI., DELIVERED APRIL 26, 1833.

GENTLEMEN,—The term *hernia* is applied by surgeons to a protrusion of parts from any of the greater cavities of the body; thus there may be herniæ of the brain, lungs, or abdominal viscera. It is to the latter cases that I now request your attention. The expression *rupture*, employed synonymously with *hernia*, signifies, however, only the abdominal form of the disease, and came into use from an erroneous notion, that the parts, through which the protrusion happened, were actually burst or torn. When any of the viscera of the abdomen protrude from that cavity, they almost always push out along with them a portion of the peritoneum, which forms a kind of pouch, in which they are contained, and is called the *hernial sac*. Of this the narrow part is termed the neck, and the more expanded part the *body*.

But, gentlemen, hernia is attended with infinite variety, so that it will not always admit of being defined to be a protrusion of the viscera, included in a peritoneal sac, for the parts may not protrude at all; the displaced or entangled bowels may form no external swelling; they may be entangled in some unusual aperture in the mesentery, or compressed by adhesions formed within the abdomen, as you see has happened in the case from which the parts in this preparation were taken; or, if they do protrude, they may not be entirely covered by a peritoneal sac. The total or partial absence of a sac, however, is the peculiarity of but few cases, as when a hernia follows the cicatrization of a penetrating wound of the abdomen, or when the sac is rendered imperfect by ulceration or

absorption, or is torn by accidental violence directly applied to the tumour.

Gentlemen, it is also of importance for you to remember, that as the bladder and cœcum are not included in the peritoneum, when they form herniæ, they have not a complete hernial sac; they do not push out the peritoneum before them, but draw after them the portion of that membrane, with which they are naturally connected. Thus a kind of sac may follow them, without covering them, and into such sac other bowels may fall.

The situations in which herniæ most frequently occur, are the abdominal ring, the navel, and a limited point below Poupart's ligament, just at the inner side of the femoral vein. They are also met with at every point of the linea alba, and, in less common instances, at the foramen ovale, at the ischiatic notch, in the perinæum, or the vagina. You may likewise meet with hernial protrusions through the diaphragm into the chest, sometimes through a lacerated opening in that muscle, sometimes through a natural aperture in it, or one from congenital malformation. The contents of a hernia are mostly either intestine or omentum, or both together. The small intestine, being more moveable than the large, is more frequently protruded, especially that portion of it named the ileum, which lies very near the ring and the space below Poupart's ligament. Then you will meet with examples, in which the protrusion will comprise merely a part of the diameter of the intestine; and others, in which several inches or feet of it may be contained in the sac.

In rarer forms of hernia, you may meet with other parts, as portions of the stomach, or liver, the spleen, uterus, ovaries, or bladder. From the two circumstances of *situation* and *contents*, are derived nearly all the various names of herniæ. Thus, when the tumour contains intestine alone, it is called *enterocele*: when *omentum* alone, *epiplocele*; and, when its contents consist of both parts, *entero-epiplocele*. You hear also of *herniæ of stomach, bladder, &c.* With respect to names derived from situation, when the protrusion is at the abdominal ring, or even merely within the

inguinal canal, the case is termed a *bubonocoele*, or an *inguinal hernia*; but if the parts come out of the same aperture, and descend further, so as to get into the *scrotum*, such form of the disease is termed *oscheocoele*, or a *scrotal hernia*. Here is a preparation of scrotal hernia, showing how the sac descends along the spermatic cord, and how distinct its cavity is from that of the tunica vaginalis.

The protrusion, which happens below Poupart's ligament, just on the inner side of the femoral vein, receives the name of *crural* or *femoral hernia*. A protrusion at the navel is termed an *exomphalos*, or an *umbilical hernia*; and, at any other point of the front of the abdomen not yet specified, a *ventral hernia*.

Protrusions by the side of the vagina, at the foramen ovale, in the perinæum, through the diaphragm, or the ischiatic notch, are named accordingly, *hernias of the vagina, foramen ovale, &c.* One kind of hernia, named from the circumstance of children being born with it, or having it very soon after birth, is called *congenital*, which is likewise singular in another respect, viz. that of having the tunica vaginalis for the hernial sac.

In the next place, gentlemen, I may observe, that when the protruded viscera create no disturbance, and readily admit of being put back into the abdomen, the hernia is said to be *reducible*; but when they cannot be put back, owing to adhesions, or their large size in relation to the opening, through which they would have to return, the hernia is called *irreducible*. If the parts be not only difficult of reduction, but subjected to such pressure, or constriction, as impedes, or deranges their functions, stopping the passage of the intestinal matter towards the anus, causing frequent sickness, with inflammation or worse consequences in the constricted parts, the case is well known among surgeons as a *strangulated* or *incarcerated hernia*.

The causes of hernia, gentlemen, are divisible into the *predisposing* and *exciting*. With respect to the first, I may remark that a natural deficiency of resistance in any part of the boundaries of the abdomen, and a loose very moveable state of certain viscera, must be regarded as the common predisposing causes.

According to the observations of Sir Astley Cooper, debility predisposes very much to the occurrence of hernia; by occasioning a relaxation of fibre, it seems to him to produce a dilatation of the apertures through which the spermatic vessels pass. If a person, debilitated by fever, returns to a habit of violent exertion before his strength is fully re-established, a hernial swelling will frequently take place. It is on the principle of general relaxation, that the same distinguished surgeon explains the remarkable frequency of the disease in old persons, especially those who work hard. Hot climates, by producing relaxation, and all circumstances which tend to bring on a sudden absorption of fat, are well-known to give a tendency to the formation of hernial swellings.

There are also many facts in support of the doctrine that herniæ are sometimes particularly prevalent in certain families, so as to be called hereditary, and no doubt this depends upon a weaker conformation of the parts where the tumours form, than is exemplified in the generality of individuals. At least such is the belief of Sir Astley Cooper, and other eminent surgeons, who have investigated this subject with the greatest success.

Then, gentlemen, we may say of the *exciting causes*, that they may all be referred to the powerful action of the abdominal muscles and diaphragm on the viscera; and this is the reason of the great frequency of the disease in the labouring classes, in dancers, in the inhabitants of mountainous countries, in the cavalry, in persons who ride hard, &c.; persons who lift heavy weights, who suffer from asthma, or from long continued cough, or who habitually exert their lungs in any kind of manner, are principally subject to hernia. Constiveness likewise creates a risk of hernia, which usually comes on when the person is straining at stool. Strictures of the urethra also promote the formation of hernia, the abdominal muscles being required to act with unusual force in order to empty the bladder. Cases are recorded, in which several hernial tumours were thus occasioned in the same individual. The same causes, which first produced the complaint are constantly tending to promote its increase. The tumour becomes larger, in proportion as the pressure against the hernial sac is stronger and more frequent. Hence the great size which it often attains in persons following laborious occupations. Its increase will also be in proportion to the less considerable resistance of the parts in which it is situated; hence the magnitude of scrotal ruptures, and the generally small size of a femoral hernia. Sir Astley Cooper adverts to one condition conducive to hernia, through an altered state of the viscera, the abdominal muscles being nearly passive; this is when the viscera become, as it were, too large for the belly, from extreme obesity, the fat accumulating in extraordinary quantities in the omentum and mesentery. The enlargement of the uterus in pregnancy, as every surgeon knows, gives a great tendency to the occurrence of umbilical and ventral herniæ, by over-distension of the abdominal parietes.

At the first moment of the occurrence of a *suddenly formed* hernia, I may observe, gentlemen, that the protruded peritoneum must be unconnected to the parts amongst which it lies, but in a very short time it becomes firmly bound to them by the adhesive inflammation, which then prevents the return of the sac into the abdomen on the viscera being reduced.

The great apparent increase in the thickness of the sac is mostly owing, not to such change in the peritoneal sac itself, but to that of the more external coverings of the tumour, as the fascia, cremaster, and cellular substance. However, there are exceptions in which the hernial:

sac really is much thicker than the rest of the peritoneum; especially when the tumour, after having been long reduced, protrudes again, and is not kept up; when it has been repeatedly affected with inflammation; or there are extensive adhesions between the sac and its contents. In the preparation which I now show you of an inguinal hernia, you see the several layers of which the sac is composed; you see also that the omentum is adherent to the sac, and that the peritoneal part of the latter is really much thickened.

The *general symptoms of a reducible hernia* are an indolent tumour, situated at one of the points of the abdomen, which I have already specified as the places for hernia; sometimes originating gradually, sometimes suddenly, and subject to change of size, being smaller when the patient lies down on his back, and larger when he stands up or holds his breath. Frequently it diminishes when compressed, and grows large again when the pressure is removed. Its size and tension often increase after a meal, or when the patient is flatulent. In many cases, colic, constipation, and vomiting, occasionally take place, seemingly from the bowels being out of their natural situation, and less capable of their usual action on their contents; but, in others, the functions of the bowels go on very quietly and regularly.

When the sac contains only a piece of intestine, forming what is termed an *enterocele*, the tumour is characterised by elasticity and uniform smoothness. No pain attends the handling of it; and, on the patient's coughing, while the surgeon's hand is applied to the part, a forcible impulse is felt, as if air were blown into the swelling. The bowel generally returns into the abdomen with great facility, a gurgling noise being frequently heard at the moment.

If the sac contain only omentum, constituting *epiplocele*, the tumour has a more flabby and unequal feel; is more inclined to be oblong than round; and if the quantity of protruded omentum be considerable, the disease is in some degree indicated by its weight, which is greater than that of an *enterocele*. Here, also, an impulse is felt in the tumour when the patient coughs. In very young subjects, gentlemen, you will mostly find the contents of a hernia to be intestine and seldom omentum.

With respect to the signs of an *entero-epiplocele*, or hernial tumour, containing both omentum and intestine, if a part of the contents slip up suddenly and with a gurgling noise, leaving behind something which is less easily reduced, you may infer that the disease is an *entero-epiplocele*.

The *general treatment of a reducible hernia* is perfectly obvious. You should advise the patient to let the protruded viscera be returned into the cavity of the belly, and to procure a truss for the purpose of preventing their descent again. The manual proceedings by which the contents of a hernia are reduced, without

the use of the knife, are termed the operation of the *taxis*, the manner of performing which varies according to the situation of the tumour, as I shall hereafter explain.

If no means be employed for reducing the parts, and keeping them reduced, there will be a constant risk of the hernia becoming strangulated by an additional protrusion of more bowel or omentum into the sac. But, besides this danger, and the loss of all chances of a radical cure, when a reducible hernia is neglected, other considerations should be pressed upon the patient, to make him understand the necessity of regularly keeping up the parts with a truss. Gentlemen, you should represent to him, that if he neglect this precaution the hernia will increase in size, so as not only to prevent all active exertion, but, if a bubonocoele, to impair the genital function by involving the integuments of the penis, and sometimes also, by the pressure, causing a wasting of the testicle. In particular, as the early period of life is that in which the opening has the greatest disposition to close, infants and children should never be suffered to be without a proper truss; and it is now well ascertained that they can wear trusses with steel springs just as well as adult subjects.

Gentlemen, though such are the doctrines which I have to offer in relation to the general treatment of reducible hernia, you ought to be apprised, that cases sometimes present themselves, in which the contents of the hernia are so bulky, that, though reducible, they cause, after their return into the belly, so much pain and indisposition, that it becomes necessary to let them continue in the sac, which should then be supported with a suspensory bandage.

Of *irreducible hernia free from inflammation, and troublesome or dangerous symptoms*.—The usual causes preventive of reduction in such cases, are, first, the bulk of the protruded parts, in relation to the opening, through which they would have to return; secondly, alterations in their form and texture; thirdly, adhesions to one another, or to the inside of the sac. The preparation, No. 728, which I now pass to you for examination, shows a general adhesion of the intestines to one another, and the inside of the sac. Fourthly, transverse membranous bands within the sac, or the neck of it. Fifthly, some herniae are rendered irreducible, because the viscera are bound down by their natural cellular connexions, though in a state of displacement. The bladder is generally incapable of being completely returned; and the hernial sac, where the cœcum protrudes, is deficient behind and at the outer side of the tumour, where the bowel has only its usual cellular attachment.

The course of the intestinal matter is always more or less obstructed in that portion of the bowels which is included in the hernia; and hence patients with irreducible *enterocele* are frequently subject to complaints of the digestive organs, colic pains, or even a total stop-

page of evacuations per anum; not the result of any constriction of the protruded bowel, but of the difficulty with which its contents pass through it.

Persons with irreducible ruptures should avoid rough exercise, support the tumour with a bandage, and keep it out of the way of all harm from pressure or bruises. They should also be careful to avoid costiveness, and all irregularity of diet.

An irreducible omental hernia, free from constriction and inflammation, may not be the cause of much present inconvenience, but, when affected with inflammation from any accidental cause, or when a portion of bowel slips into the sac with it, severe and fatal consequences may ensue.

General symptoms of a strangulated hernia.

—The first symptoms are a tumour in the situation of the hernial protrusion; attended with pain, not only in the part, but about the diaphragm, followed by continual eructations, sickness, inclination to vomit, suppression of stools, and some acceleration of the pulse. Now, it is a curious circumstance, that the suppression of stools is often as complete and as irremovable by purgative medicines, when only a small portion of the diameter of the bowel is strangulated, in the manner exemplified in the preparation before us, as when an entire fold of it is pinched. The action of a clyster on the bowels below the stricture often produces a stool after strangulation has taken place; but when they have once been emptied, the most irritating clysters have no effect. If the reduction be delayed, the vomiting and eructations become more frequent—all the contents of the stomach, and afterwards those of the bowels down to the stricture, being rejected. There is great anxiety and restlessness, with a small, quick, hard pulse, and generally cold extremities.

After a time, hiccough comes on, the pulse sinks, and the whole body becomes covered with a cold clammy perspiration. Mortification now takes place, beginning in the protruded viscera and extending to the containing and neighbouring parts.

The patient may now experience a sudden feeling of relief, but this is only temporary. The tumour becomes emphysematous, a sure sign of the gangrenous mischief within it. In this state, the gut either goes up spontaneously or is returned with the smallest degree of pressure; but the hiccough and cold sweats continuing, the pulse becomes more and more rapid and irregular, and death soon follows.

When the body is examined, the whole surface of the peritoneum is found inflamed, the intestines participating in the disorder, particularly those above the stricture, which are considerably distended with air. From the strangulated part downwards, the intestine is generally smaller than usual, and sometimes not inflamed. All these circumstances are illustrated in the preparation, No. 713, and two coloured waxen models on the table. The

preparation exhibits a femoral hernia, with the intestine mortified, as evinced by its colour. The distended inflamed portion within the abdomen is the upper part of the canal. The strangulation which was in the neck of the sac implicated a mere knuckle of intestine, without any further protrusion. The convolutions are also frequently connected together by recently formed adhesions; a turbid puriform fluid is effused in the abdomen; and not unfrequently spots of gangrene are seen on the intestines, as is well delineated in the casts before us.

The symptoms of a strangulated epiplocele are less severe and rapid, and stools may generally be procured by purgatives and clysters; but this is sometimes attended with great difficulty, and the sickness and vomiting are, for the most part, truly distressing. Here, gentlemen, you see a preparation exhibiting the production of a permanent stricture of the inner coat of a portion of bowel that had suffered strangulation in a hernia; an exceedingly rare occurrence.

General treatment of strangulated hernia.

—Gentlemen, I deem it very important that you should always remember the necessity of not losing too much time in the trial of means not to be depended upon for procuring the reduction of the parts; for the rapidity with which gangrenous mischief sometimes takes place in the hernia, attended by a dangerous and fatal degree of inflammation within the abdomen, is very remarkable. Now, we know that the greater number of patients, who die after operations for strangulated herniæ, do not die of those operations abstractedly considered, but rather of the effects of the disease; and that if the knife were used more promptly, life would more frequently be saved. I fully coincide in the opinion entertained by many surgeons, that we should save many more lives by operating on strangulated hernia much sooner than is generally done. I would recommend you to try fairly and promptly those means which are the most likely to promote the reduction of the hernia, and if they fail, not to waste time in the useless repetition of them, or the employment of others, known to be less efficient.

The *taxis*, or an attempt to reduce the parts with the hand, is, of course, the first proceeding for adoption. For this purpose, the abdominal muscles and femoral fascia should be relaxed by inclining the chest forwards, and bending the thigh and rotating it inwards. In the external inguinal hernia, the pressure should be directed upwards and outwards, along the course of the spermatic cord; but, as the femoral hernia passes first downwards and then forwards, the pressure in this case must be directed first backwards and then upwards. In umbilical and ventral herniæ, it is to be made directly backwards.

No violence ought to be used, as it can be of no service, and must increase the inflammation of the bowels. The intestine may even be

burst by too much force, or the sac forced into the abdomen, with viscera strangulated by its neck. If the first trial of the taxis should fail, you may put the patient into a warm-bath, if it can be prepared without too much loss of time; and while he is in it, take blood from his arm. If the warm-bath should require much time for its preparation, I would advise you to dispense with it, and bleed from the arm.

The object of the warm-bath and bleeding is to render the patient weak and faint, to bring on a kind of general collapse, during which the taxis may often be practised with success. If the patient should fall into this state, therefore, the opportunity of trying the taxis again is to be taken.

Supposing, however, you were not yet able to succeed, what ought to be done? You should next try the united effect of cold or ice applications to the swelling, and of an infusion of tobacco thrown up the rectum. ℥j. of tobacco is to be infused for ten minutes in a pint of boiling water poured upon it; the liquor is then to be strained, and one half of it injected first, and, if this produce not too violent effects, the other half is to be thrown up afterwards. When the patient is under the influence of the tobacco, and the tumour has been subjected to the cold applications some little time, the taxis is to be tried for the last time, and if it now fail, and the symptoms are urgent, I think the operation ought to be done without further delay.

I have little faith in purgatives and opium, except in cases of strangulated epiplocele, or where you have reason to believe that a part of the contents of the tumour has been reduced.

You will sometimes be called to cases, in which so much time has been lost, that you will only just have an opportunity of trying the effect of tobacco and cold, or even not of them.

As the operations and various matters relative to herniæ, would be unintelligible without an anatomical description of the parts concerned, I next enter upon this important part of the subject.

Anatomy of Inguinal Hernia, or Bubonocèle.—It will be impossible for you, to understand the subject of inguinal hernia, unless you have made yourselves acquainted with the anatomy of the passage through which the spermatic cord naturally proceeds, in order to reach the scrotum, and through which the most common form of inguinal hernia takes place. You must also understand the coverings of the spermatic cord, because they are also the coverings of inguinal hernia; and, in addition to these matters, you should have a clear idea of the situation of this hernia, in relation both to the spermatic vessels and the epigastric artery.

Now the *abdominal ring*, or triangular opening in the tendon of the external oblique muscle, the base of which corresponds to the crista of the os pubis, is the external termina-

tion or outlet of the canal, through which the spermatic cord passes. The upper, inner, and weaker pillar of this opening is inserted into the symphysis of the os pubis, and its lower, outer, and stronger pillar into the angle and crista of that bone. In the living subject, it is not an unclosed aperture; for, besides being occupied by the cord, it has the *intercolumnar fascia* extended over it.

Gentlemen, I may next remind you, that the inner opening or commencement of the passage, designed for the spermatic cord,—the very place, in fact, where the viscera first protrude in the most common kind of inguinal hernia,—is not situated directly behind the *abdominal ring*, but about an inch and a half from it, in the directions towards the anterior superior spinous process of the ilium. Or, I may say, in other words that the *inguinal canal*, as it is generally named, is about an inch and a half in length; the *internal ring* being situated very nearly midway between the symphysis of the pubes and the anterior superior spinous process of the ilium.

This description will, of course, lead you to know, that the direction of the inguinal canal must be oblique, extending downwards, inwards, and forwards.

But, you will naturally ask, what parts form the inguinal canal? In order to understand this part of the subject, you should remember, that a thin fascia, termed the *fascia transversalis*, first accurately described by Sir Astley Cooper, is extended from the inner margin of Poupart's ligament, over the posterior surface of the transverse muscle, thus forming a kind of partition between the abdominal ring and the peritoneum, and also forming, with a portion of the united fibres of the transverse and internal oblique muscles near the crista of the os pubis, the posterior boundary of the inguinal canal, the anterior side of which is formed, to the extent of its first third from the inner ring, by the transversalis and internal oblique muscles, and, in the remainder of its continuation, by the aponeurosis of the external oblique.

I wish you likewise to understand, that the precise point, at which the most common forms of inguinal hernia begin, corresponds, in the adult, to the passage of the spermatic cord under the edge of the transverse muscle. In the sound state, this part of the peritoneum has a small funnel-shaped depression in it; and it is this small digital kind of pouch, whose progressive enlargement constitutes the hernial sac; the hernia in its course always following the course of the spermatic cord, in front of the vessels of which it is situated. Here, gentlemen, is a preparation exhibiting inguinal hernia in the first stage of its formation; and in this other preparation you may observe the hernial sac in its incipient state, not larger than the end of the finger of a glove. The tumour protrudes over the cord, and the intestine is pressed into the little pouch.

In point of fact, the opening which constitutes the internal ring, or commencement of the inguinal canal, is the aperture in the fascia transversalis, designed for the passage of the spermatic cord into that canal. Now the cord, in passing through this opening, carries along with it a covering derived from the margin of such aperture in the fascia transversalis, which covering is termed the *funnel-shaped process* of the fascia transversalis. It is the least important of the investments of the hernia; for, after it has descended a little way, it is lost in the cellular tissue, between the peritoneal hernial sac and the cremaster.

The spermatic cord, invested by the *funnel-shaped process*, then passes under the lower edge of the transverse and internal oblique muscles, and here it receives its second covering from the *cremaster muscle*.

The abdominal ring, you know, is closed by the *intercolumnar fascia*, and from this the cord also derives a third investment, termed the *spermatic*, or *intercolumnar fascia*; and, in addition to these several coverings, namely, —the *funnel-shaped process* of the fascia transversalis, the *expansion of the cremaster*, and the *spermatic* or *intercolumnar fascia*; the cord is also covered by the *superficial fascia*, placed immediately under the integuments.

Now these investments of the cord are also the coverings of the common bubonocoele, or inguinal hernia, which descends through the inguinal canal. The hernial sac has between its external surface and the inner surface of the cremaster the *funnel-shaped process*, or investment derived from the margin of the aperture in the fascia transversalis. On the outside of the cremaster, the sac has the *spermatic fascia*, derived from the intercolumnar, and, external to the spermatic fascia, the *fascia superficialis*, which is immediately under the common integuments.

Gentlemen,—there is one circumstance which I must not omit to mention, namely,—that Sir Astley Cooper believes the inguinal canal to be endowed with muscular contraction, which, under the action of the abdominal muscles, serves to close it, and lessen the propensity to hernia. He observes, that the lower edge of the transverse muscle begins to be attached to Poupart's ligament almost immediately below the commencement of the internal ring, and that it continues to be inserted behind the spermatic cord with Poupart's ligament as far as the attachment of the rectus. Sometimes, he has found a portion of muscle descending from the tendon of the transversalis, in the course of the linea semilunaris, to be inserted into the fascia transversalis, behind the cord, and into Poupart's ligament, and a preparation exhibiting this conformation he was so obliging as to show me a few months ago. Sir Astley believes that this encircling of the internal ring and upper part of the inguinal canal by muscular fibres, may be a cause of strangulation in the external bubo-

nocele. However, the anatomical facts on which this doctrine is founded, are, I suspect, only deviations from what may be regarded as the normal or most usual conformation of the parts. Although we may not be disposed to explain the supposed spasmodic nature of some kinds of strangulation by the cause referred to by Sir Astley Cooper, we ought to feel obliged to him for his original explanation of the internal ring being occasionally surrounded by muscular fibres derived from the transversalis. His greatest discoveries on the subject of this hernia, however, appear to me to be those relating to the first correct description of the internal ring, and of the fascia transversalis.

Next, gentlemen, let us consider the situation and course of the spermatic vessels and epigastric artery, in relation to inguinal hernia.

As the epigastric artery naturally runs first behind the spermatic cord, and then about a quarter of an inch from the pubic margin of the internal ring, and as the viscera protrude through this aperture, and follow the course of the cord, they must be situated on the outer side of that artery, which passes first behind the neck of the sac, and then at its inner side, in its way to the inner surface of the rectus muscle. Hence, the inner margin of the neck of the sac is encircled, as it were, by the track of the vessel, as you may observe in this dried preparation of half the pelvis, with the arteries and veins injected, and the hernial sac preserved. Here, also, is another preparation of scrotal hernia, with the hernial sac dried and varnished, the vas deferens filled with quicksilver, and the epigastric artery injected, a large branch of which is seen running down the sac.

In recent bubonocoeles, the internal and external opening of the ring are at some distance from each other, the first being situated obliquely upwards and outwards in relation to the former; but the pressure of the protruded viscera gradually forces the internal opening more towards the pubes, and nearer to the abdominal ring, so as to render the posterior side of the neck of the hernial sac and of the inguinal canal very short. Thus in external inguinal hernia of long standing, the opening into the abdomen is almost direct, and the epigastric artery becomes situated nearer the pubes than in the natural state.

But, gentlemen, though in the most frequent form of bubonocoele the protrusion begins at the point which I have described, and follows the course of the spermatic cord, passing all through the inguinal canal, and having the epigastric artery behind and at the inner margin of the neck of the sac, circumstances are very different in another less common variety of bubonocoele, where the viscera, instead of beginning to protrude at the internal and upper opening of the inguinal canal, and descending through that canal by following the course of the spermatic cord, are thrust out at the point directly behind the abdominal ring, together with the portion of the

fascia transversalis, forming, with the conjoined fibres of the internal oblique and transverse muscles, the posterior boundary of the inguinal canal, immediately behind the abdominal ring, out of which the viscera then protrude in a direct manner. Here the hernial sac instead of passing over the spermatic cord, as in the most frequent form of bubonocoele, lies on its inner or pubic side; and the epigastric artery now pursues its course in front of the neck of the sac, at the usual distance from the upper and outer angle of the abdominal ring.

Now, as in the most common examples of inguinal hernia, the protrusion is on the outside of the epigastric artery, which winds under and round the inner margin of the neck of the sac, the case is termed the *external bubonocoele*, while the less frequent one, in which the protrusion takes place immediately behind the abdominal ring, out of which the viscera pass without having descended through the rest of the inguinal canal, is named the *internal bubonocoele*; a case, most particularly claiming recollection, as the protrusion is *at the inner or pubic side of the epigastric artery*. One case is also sometimes called the *oblique inguinal hernia*; and the other the *direct, or ventro-inguinal*.

In this internal direct inguinal hernia, the sac pushes out with it the fascia transversalis, situated immediately behind the ring, and must either lacerate or displace the united fibres of the internal oblique and transverse muscles at this point. As the hernia does not follow the spermatic cord through the inguinal canal, the cremaster only covers it near the abdominal ring. With this exception the coverings of the hernia are the same as in the external bubonocoele.

Here, gentlemen is a preparation of the os innominatum and abdominal muscles, exhibiting the sac of an *internal inguinal hernia*, or, as it is often termed, *direct inguinal* or *ventro-inguinal* hernia. Within you may observe the origin of the epigastric artery. To the inner side of this vessel, you may notice the neck of the sac, and not to the outer side of it, as in the external, or oblique inguinal hernia.

Now, gentlemen, after having explained to you the very different situation of the epigastric artery, in relation to the neck of the sac of an internal bubonocoele, from what prevails in the external one, you will immediately see how important it is to distinguish one case from the other in practice. In fact, if you were to divide the stricture in the same way in each case, you would often wound the epigastric artery. The discrimination of one case from the other is also important with reference to the manner of performing the taxis, and the kind of truss, which should be selected.

In scrotal herniae of large size, the spermatic vessels, instead of forming a chord, may be disjoined by the pressure of the swelling, the vas deferens being situated on one side of the sac, and the spermatic artery and veins on the other. In general, towards the upper part

and neck of the sac, the cord is not much unravelled, but, as its component vessels proceed downwards, they diverge more and more, and spread themselves over the sides, or even over the front of the sac.

I have already mentioned the close adhesions which a hernial sac soon contracts to the cellular substance on the outside of it, and consequently the rarity of its reduction. Such an event, however, sometimes happens, especially in the femoral and internal bubonocoele, for in the external one, the manner, in which the sac becomes connected to the spermatic cord, makes it much less likely to take place.

Bubonocoeles are most common in the male sex; but are occasionally met with in women, and then the round ligament of the uterus bears the same relation to the tumour as the spermatic cord does in males. Of course in such a case, the hernia has not the covering which, in the male subject, it derives from the cremaster. You may also meet with rare examples in which the internal bubonocoele occurs in women. Some months ago I operated upon a Mrs. Smith for a strangulated hernia of this description, a tailor's wife, in Cumberland-street, Middlesex Hospital. As she had had no stools for three or four days when I went to her, and the symptoms were urgent, I performed the operation at once, without trying any previous means but the taxis, and in about a week she was perfectly well.

Gentlemen, let me next call your attention to some of the principal points of difference in the symptoms of *oblique and direct inguinal hernia*. In the oblique inguinal hernia there is an *oblong swelling*, extending obliquely inwards and downwards; in the direct hernia, the parts pass from behind straight forwards, and form, on the outside of the abdominal ring, a circular globular swelling, suddenly formed by some violent effort. If any obliquity occur in the direct inguinal hernia, it is in a course towards the linea alba, and not towards the anterior superior spinous process of the ilium. Then, in the oblique inguinal hernia, the spermatic cord is situated behind or under the sac; but in the direct bubonocoele it lies to the outer side, or upon the external half of the front of the neck of the hernial sac. In the direct inguinal hernia, where the sac adheres to the cord, the testicle is not situated exactly under the fundus of the sac, as in the oblique inguinal hernia, but either at the forepart or on the outer side of it.

In the internal bubonocoele, the epigastric artery always ascends obliquely inwards at the outer side of the neck of the hernial sac, though Hesselbach found an exception to this in one rare case, where that artery proceeded from the obturator. Sometimes this hernia consists of two protrusions, divided from each other by strong tendinous fibres in the centre of the fascia.

In some other instances, the fascia transversalis is lacerated, not dilated; and occasionally a direct inguinal hernia is accompanied by an oblique one.

Gentlemen, you will now understand why, in the oblique hernia, the pad of a truss should always press, not merely upon the abdominal ring, but upon the track of the inguinal canal; and why, in the direct hernia, the pad should only act upon the abdominal ring. In the taxis, the direction of the pressure should be different; for, in the external bubonocoele, the viscera should be pushed upwards, backwards, and outwards; in the internal, upwards and backwards. Then, in the operation on strangulated cases, a still more important thing to be remembered, is the different directions which should be given to the incision for the division of the stricture: in the oblique case, you may cut upwards and outwards, with perfect safety, to the epigastric artery; but not inwards or towards the linea alba; whereas, in the direct hernia, the cut must not be made outwards but inwards, the epigastric not being displaced from its natural situation. In order to avoid doing mischief by mistaking one sort of hernia for another, Sir Astley Cooper is right in advising the incision always to be made directly upwards.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XXVI.

Treatment of Encephalitis in the Adult—General and Local Bleeding—Employment of Cold—Abercrombie's method—Blisters—Mercury—Danger of Emetics—Opium—Employment of Coercion—Violent Counter-irritation in the advanced stages—Treatment of Partial Encephalitis—Inflammatory softening.

GENTLEMEN,—We have now to enter upon the treatment of inflammation of the brain; and you will find, that a knowledge of the general principles of the treatment of cerebral inflammation will be quite sufficient to guide you, even in the management of cases which present apparent exceptions to the ordinary symptoms. The truth is, that the principles which should regulate the treatment of inflammation of the brain are nearly the same in all cases.

I shall commence with the treatment of the acute form in the adult. Acute phrenitis in the adult is an exceedingly severe disease, characterised in its first period by an high exaltation of the functions of the brain, and in its second by a corresponding depression. In this form of disease we have generally high fever, a strong bounding pulse, throbbing of the carotids, intense pain of the head, great brilliancy of the eye, with intolerance of light, vivid redness of the face, a ferocious countenance, and furious delirium.

Under such circumstances there is no time to be lost; the brain is a delicate organ, and cannot bear much disease, and its powers of recovering from idiopathic disorganisation seem much less than those of the lungs or abdominal viscera. Indeed, we must believe that, notwithstanding the assertions of Lallemand, it remains to be proved that recovery can take place after the stage of softening has set in, in idiopathic encephalitis. The brain differs from the lungs or digestive organs in having no excretory duct for the products of inflammation, and hence one cause of the greater danger of its idiopathic inflammations than its traumatic, where an opening is formed in the skull. In such a case, you have to apprehend two pathological lesions, the inflammatory softening of the substance of the brain, and the inflammation of its serous membranes, with effusion into their cavities. The patient, too, may die from congestion, or even an apoplectic effusion may occur, illustrative of the proposition of Broussais, that all encephalic irritations may produce an apoplexy. I have seen this termination, even in the infant under a year old; in such a case I once saw an apoplectic effusion which had supervened in the course of an arachno-cerebritis, and which amounted to several ounces of blood. Every moment is precious, and no consideration should induce you to put off even for an hour the adoption of the most rigorous measures. In the first place, you must bleed; and here let me remark, that blood-letting should be performed, so as to make a decided impression on the symptoms. It will often happen, that, from the state of uncontrollable fury which the patient is in, it is dangerous and almost impossible to bleed him. Here you must endeavour to moderate the delirium, and there is no way by which you can accomplish your purpose so fully as by cold dashing. Where there is high delirium, I believe you will always find it the best plan to precede venesection by throwing a few basins of cold water over your patient's head. This will procure an interval of comparative tranquillity, during which you can open either a vein or an artery with convenience and safety. Of course, if any thing like collapse ensues (which is possible), you will not bleed immediately. The object of the cold pouring, under these circumstances, is to obtain such a diminution of the fury, as will allow of your bleeding the patient with safety as to the operation. If you cannot reduce the cerebral excitement by this means, it will then be necessary to put on the strait waistcoat, *pro tempore*. There is a difference of opinion among medical men with respect to the mode of abstracting blood; some prefer taking it from the arm, some from the jugular vein, and some from the temporal artery. Now, I am inclined to think that it is better to open a vein in the arm, and that venesection performed in this way will be found to answer every purpose. It is said, that if you take blood from the temporal artery or jugular vein, you

deplete the brain more directly than you would by opening one of the brachial veins. This may be true, though I think it still remains to be proved that the drawing of a smaller quantity of blood from these vessels will have a more powerful effect on the system than from the arm. If you open the temporal artery, there are two disagreeable circumstances which you should be prepared to meet. In the first place, the patient is in a state of furious delirium, you don't know how long this may last, and it may happen, that in one of his paroxysms he will tear off the bandage, and, if not watched, bleed to death. A case of this kind occurred not long since, in the person of a gentleman of this city, who had the temporal artery opened. He tore off the bandage, and a terrible hæmorrhage ensued; assistance was procured, and the bandage re-adjusted; he tore it off a second time, and died shortly after, his death being evidently accelerated if not actually caused by the quantity of blood lost. Again, it is possible that an aneurism may be formed as a consequence of the operation, which may excite a determination to the head, and tend to keep the patient in a state of excitement. Thirdly, you must employ a bandage to secure the artery, and to this there is a strong objection, in consequence of the pressure which it makes on the external vessels of the head. I am therefore strongly opposed to opening the temporal artery in cases of acute inflammation of the brain, accompanied by high mental or muscular excitement. Now, with respect to the jugular vein, you are aware that to command this vessel pressure is also required. How this pressure can be made without interfering with respiration and compressing the veins of the neck, so as to add to the existing congestion of the head, I am at a loss to know. I would advise you, therefore, when you bleed in phrenitis, to prefer opening a vein in the arm; by making a free incision you can draw blood in such a way as to make an impression on the system, fully equal to that produced by either of the foregoing modes; and without subjecting your patient to the same degree of inconvenience or risk. The quantity of blood to be taken away must be regulated by the age, strength, and constitution of the patient, as also by the intensity of the disease. Where you have to deal with a young man of robust constitution, your first bleeding may amount to thirty ounces. You will often find it difficult to produce fainting in this disease, for the excited condition of the brain keeps up a constant determination to that organ and prevents syncope. The same difficulty is met with in cases of hypertrophy of the left ventricle, which causes a great determination to the head.

Your next step is to have the head shaved. Never omit this. The very circumstance of freeing the head from the covering of hair, and permitting the free contact of air with the

scalp is of advantage; and if you wish to employ cold applications, you cannot do so properly without premising this operation. After you have done this, you should apply a large number of leeches to the scalp, or if you cannot readily procure leeches, employ instead of them light scarifications to the temples and nape of the neck, and keep on the cupping-glasses until you have obtained a sufficient quantity of blood. By acting in this way with promptness and decision, you arrest the violent symptoms, and gain time.

In treating a case of this kind it is a very common practice to use cold applications. They are for the most part applied in shape of a cold lotion to the head, but I need not tell you that this is a very imperfect mode of using them, and indeed I have seen but very few persons who were acquainted with the proper mode. Persons are in the habit of supposing that the mixing of a certain quantity of saline ingredients, with water, should produce a very cold lotion, and so it does indeed while the salts are dissolving; but as soon as this is accomplished, the mixture rapidly acquires the temperature of the surrounding air. The solution is generally prepared by the apothecary (and sent in a bottle, as if they could cork up the cold), but the cold is quickly lost, and, in a few moments after the lotion has been applied, you will find it quite tepid, and passing into a state of vapour. Now if you wish to derive any benefit from the use of cold applications, you must stand by yourself, and see the thing properly done. The object is to have the scalp kept constantly cold, and this can be done only by the repeated application of cold lotions. If you prefer saline lotions, you should have them made by the bedside, and applied *while in the act of solution*, or you should put a quantity of ice into your lotion, for while a single piece of the ice remains undissolved, the temperature of the lotion will be very little above the freezing point. A very good way, is to have a jar of cold water, with a quantity of ice in it and to apply cloths dipped in it every minute, taking care not to immerse the hot cloth into the iced water, until it has been wrung out in another vessel of water. You may also use the ice cap, though this is a painful remedy. But the mode of using ice to the head which I prefer in all cases, and particularly in that of the child, is to take a piece of smooth ice, about the size of a dollar, and half an inch thick, this is to be placed in the hollow of a fine cup sponge, and steadily moved over the whole shaved scalp. By this mode you prevent the pain which the iced cap produces, and the sponge absorbs the water produced by melting, and the application may be continued for an indefinite length of time. But one of the best modes of applying cold to the head, is that recommended by Dr. Abercrombie, and, as far as my experience goes, I can safely affirm that there is scarcely any remedy of such unequivocal value in acute inflammation of the

brain or its membranes. Dr. Abercrombie's mode is this—the scalp being first shaved, you direct the patient's head to be held over a basin, and then taking a jug of cold water, pour its contents over the head from some height in a small continuous stream. This measure, simple as it may appear, is one of extraordinary efficacy. In fact so great and instantaneous is the depression of the vital power produced by this mode, that it must be used with caution. There are numerous cases of persons in the highest state of maniacal excitement, reduced in a few moments to a low and weak state by this powerful remedy. There are also instances of its rapidly depressing effect in the early stages of acute hydrocephalus. I have used it more in the phrenitis of adults, than in the hydrocephalus of children; but in the latter disease I know many instances of its value, and believe it to be only secondary to the application of leeches. In acute inflammation this form of cold effusion should be employed every hour or half hour, according to circumstances, and if you wish to increase its efficacy, you can do it by placing the patient's feet in warm water at the time of its application. Here then, gentlemen, is the first set of remedies you should employ in a case of acute phrenitis; a full bleeding from the arm, premising it, if there be great maniacal excitement, by dashing a basin of water over the patient's head; shaving the head, and applying a large number of leeches, or if these are not within reach, the use of cupping; and, lastly, the constant application of cold lotions, or the use of the cold effusion after the manner employed by Dr. Abercrombie. These are the great measures which should be boldly and promptly put in practice, in order to counteract the first violence of a case of acute inflammation of the brain.

You will next act upon the bowels by purgatives. This is a matter of the deepest importance, for there is hardly a disease in which the judicious administration of purgatives has been followed by more decidedly beneficial effects, than in inflammation of the brain, where the digestive tube has been in a healthy condition. Purgatives are also found to be of great benefit in the simple hydrocephalus of children, and in several cases it has been observed that the disease did not yield even after active bleeding, until purgation had been employed. Dr. Abercrombie speaks in the highest terms of the value of purgatives, even after coma has set in. The purgatives which are generally used are those of the drastic kind, and they may be given by the mouth or in the form of enemata.

Such are the rules for the treatment of the ordinary form of acute encephalitis. I shall now make a few observations with respect to the local applications. It may not be necessary to repeat the venesection, particularly if the means which I have recommended be put in practice in a regular and proper manner, but it will in most cases be requisite to repeat

the leeching. *Even in the advanced stage of the disease, and after coma has made its appearance, Dr. Abercrombie lays great stress on the benefits derived from the application of leeches;* and I think I have myself saved some lives by the employment of leeches, even after the supervention of coma. In all violent cases I would recommend strongly to you the using relays of leeches, from the first, to keep up a continual detraction of blood. In addition to this, the patient must be kept perfectly quiet, all loud sounds, and the stimulus of light avoided; the room should be kept cool and well-aired, the bed-covering light, the attendants few, and the nurse should be a person of cool temper and steady disposition.

These are the principal measures to be employed in the treatment of acute inflammation of the brain in the adult; there are certain cases, however, in which you may add to these measures others of a different kind, particularly in cases where the disease has occurred as a consequence of the metastasis of inflammation from other parts. Suppose you have a case of rheumatism, or of some suppressed evacuation in which there is a metastasis to the brain. Under such circumstances, while you employ the means I have mentioned for the purpose of subduing cerebral inflammation, you will also put in practice the best measures for restoring the original disease. Here, however, you should bear in mind, *that your attempts to bring back the original disease are always to be looked upon as secondary to those for the direct removal of the existing irritation of the brain.* Some practitioners, in such cases, content themselves with endeavouring to restore the original affection, but this is playing a dangerous game. An organ of vast importance to life is affected, and you cannot calculate how far the inflammation may proceed. You should never neglect taking proper steps at first to reduce inflammation, while at the same time you need not neglect the means calculated to bring back the former disease. If the encephalitis be caused by the suppression of bleeding piles, or a sudden checking of the menstrual flux, leeches to the anus or vulva are found useful along with the direct treatment. If the disease be produced by the repression of an exanthematous eruption, the same principles apply. You should never omit employing the means for bringing back the original affection, but you should always recollect that they are to be secondary to the measures adopted to directly relieve the cerebral excitement.

With respect to the use of blisters, the same rules apply here as in other cases of disease treated of during the course. They are never to be used in the early stage of the disease, and while active inflammation is present; and, as a general rule, I believe it is better to apply them to the nape of the neck, or the inside of the legs, than directly to the head. There is only one case in which you can

apply them with advantage to the head itself, and this is, where there is coma, with a cool skin. Here the stimulus of a blister is frequently found to be highly useful.

As to the use of mercury in cases of acute cerebral inflammation, I think we have not as yet a sufficient number of facts on which to form any decided opinion. If we look to hydrocephalus, we shall find that there are many cases in which the symptoms did not yield to the ordinary measures until mercury was employed; this, however, we do not find to be so much the case in the acute inflammation of the brain in the adult.—I shall return to this subject on a future occasion.

I have little doubt that emetics are very dangerous in this disease, from the determination to the head which they produce.

Any of you, gentlemen, who has vomited, cannot forget the violent sense of tension about the head, with which the act is accompanied; and, if the brain be in a state of acute inflammation, you can readily conceive how injurious such an effect must be. The use of emetics in this disease has been adopted in consequence of a misconception of the opinions of Dessault. He attributed extraordinary efficacy to the use of tartar emetic, in cases of injuries of the head. But you must be aware that Dessault did not give tartar emetic so much with the view of exciting emesis, as of *producing a degree of nausea calculated to keep down inflammatory action*. Morel, who was a pupil of his for five years, makes a statement to this effect, and says that so far from proving beneficial when it vomited, the tartar emetic was always attended with unfavourable results. When it acted on the skin, or by stool, he says the effects were favourable; but when it vomited, the symptoms of cerebral excitement were always increased. Under these circumstances, I think you should be cautious in having recourse to the use even of tartar emetic, after the manner of Dessault; for even in this way you run the risk of vomiting. On this point we have eight very instructive cases given by Lallemand. In the first two cases, where emetics were used, the head had been merely threatened. The emetics were followed by profuse vomiting, and this by symptoms of *violent cerebral excitement and rapid death*. The third case was that of a patient who had apoplexy: the emetic was followed by symptoms of inflammation of the brain and death. On dissection there were marks of inflammation discovered round the clot. Now it has been observed in several instances, that where the substance of the brain round an apoplectic clot became inflamed, that, in addition to the phenomena of apoplexy, symptoms of a spasmodic affection of the muscular system supervened. Here we see that, after the use of an emetic, these symptoms appeared, and their nature was verified by dissection. In the remaining five cases, where emetics were

employed, the cerebral affection was rather increased than diminished; and, in some of them, disease of the digestive tube was superadded. Weighing these circumstances calmly, I think the use of emetics in acute inflammation of the brain may be considered dangerous.

With respect to opium, I must say, that I am strongly opposed to its employment, at least in the early stage of encephalitis. I have seen many cases of hydrocephalus in children, in which opium seemed to be decidedly injurious; and I believe that in all cases where there is congestion of the brain, its employment will be attended by bad effects. But when all the symptoms of active inflammation have passed away, and when there remains a peculiar nervous condition of the brain, characterised by symptoms of mental excitement and persistent watchfulness, somewhat resembling delirium tremens, here, I believe, that you may have recourse to opium with much benefit. In many cases, where the antiphlogistic treatment had been properly employed at the commencement, there frequently remains a neurotic condition of the brain, accompanied by great irritation and absence of sleep; and in such cases I have seen much good resulting from the use of opiates. When I speak of fever I shall return to this subject.

In the treatment of this disease, I am anxious that you should always bear this principle in mind,—that you cannot be too cautious in adopting means of coercion. Coercion has always a bad effect: it should never be resorted to, except in cases of extreme necessity; and you should never suffer the patient's attendants to employ it without your express permission. It is a common practice in hospitals, where the attendants always wish to save trouble, to put on the strait waistcoat as soon as the patient exhibits symptoms of delirium. What is generally the result of this treatment?—The poor sufferer becomes irritated by confinement, and uses the most violent efforts to liberate himself; his struggles increase the excitement of the brain, and prevent the measures you employ from taking effect. I have known many melancholy cases, illustrative of the abuse of the strait waistcoat. I shall give you one:—A female, of delicate habit, was attacked with fever and some delirium. She was supposed to labour under disease of the brain. They put a strait waistcoat on her, and tied her down to the bed, where she remained for several days in a most deplorable state. A medical man, who was called in to see her at this time, found her in the situation described, with her head shaved and blistered, and her strength sinking. It struck him that there was something peculiar in the case, and he asked her several questions with the view of testing her sanity; and, finding that she answered rationally, he immediately directed

that the strait waistcoat should be taken off. She then told him that, during the whole course of her illness, she had laboured under pain of the right side. He examined her side, and found a large tumour in the situation of the liver. There was also an eschar on the back. She died shortly afterwards; and, on dissection, the liver was found to be in a state of extensive suppurative disease; the brain perfectly healthy. It is unnecessary for me to make any comment on this case.

While, however, I deprecate coercion as a common mode of proceeding, I fully admit that cases will occur that demand it for the safety of the patient. The dreadful tendency to suicide is one of the characters of this disease, and must never be forgotten in any case. All that I wish to impress upon you is, that coercion must be used with great caution, and only so long as it is absolutely necessary. When we come to treat of the nervous symptoms in fever, I shall recur to this subject.

In all cases of cerebral disease you should never omit inquiring into the state of the bladder, for there is often retention of urine. This is to be obviated by drawing off the urine with a catheter, two or three times a-day.

You will meet with cases of cerebral inflammation in the last stage, with profound coma, general paralysis, an imperceptible pulse, and tracheal rattle. It is a melancholy thing to be called to a case of this description, where the ordinary means furnished by medicine are so inadequate to the removal, or even the alleviation, of symptoms; and yet it is a fact, that, even under these circumstances, cases have been cured by the adoption of an extraordinary measure. This consists in the employment of enormous and sudden counter-irritation, by pouring boiling water over the lower extremities, while, at the same time, ice is applied to the head. This is certainly an extraordinary and barbarous method; but it has succeeded in rescuing the patient, as it were, from the jaws of death. One of the most singular cases of this kind is recorded by Lallemand—that of a man upwards of sixty, who, in consequence of a fall on the head; was attacked with encephalitis, which was mistaken for an essential fever until the tenth day. At this time he was first seen by Lallemand, who found him labouring under severe and long-continued syncope; the right extremities flexed; the hand firmly closed; the surface on this side insensible; the eyelids closed; the eyes turned up, squinting, and insensible to light; complete loss of hearing and intelligence. The body was covered with a cold viscid sweat; the respiration frequent and stertorous, and the pulse absent. Lallemand proposed pouring boiling water on the ankles, and, at the same time, applying ice to the head, an advice which was consented to with great reluctance by the other medical attendants. At the moment the boiling water was

applied, there was a sudden motion of the whole body: the left arm was agitated, the eyes opened, and the pulse could be felt at the wrist. In half an hour the boiling water was applied to the thighs with still greater effect; colour returned to the face, and the pulse became fuller. From this time improvement went on. Deep suppurating wounds were produced by the boiling water, which took more than six weeks to cicatrise. The patient's recovery was perfect.

In Dr. Mackintosh's work, you will find this practice recommended. It is, indeed, an extreme remedy, and one which, for many reasons, practitioners would have repugnance to use; but it is well to be acquainted with such a powerful remedy, and to know that it has succeeded under the most desperate circumstances.

With respect to partial encephalitis, the principles of treatment are the same. In this form of disease, you will often have to contend with the prejudices of the patient, and sometimes of practitioners who do not recognise its existence. Its symptoms, you will remember, may at first appear slight or insidious, and to the superficial observer less referable to the head than elsewhere; yet the disease is full of danger, slight though it appear. The recent researches on this subject have shown, too, that it is commonly a comparatively acute disease. Andral gives a table, showing the periods in one hundred and five cases: in eighty-nine of them death occurred within a month. The liability, too, of secondary complication, with general congestion, arachnitis, or apoplexy, must be always borne in mind.

When the symptoms of a local encephalitis are decided, I think you should always commence by bleeding from the arm, and then apply relays of leeches and cold lotions to the opposite side of the head. You will also find the application of tartar emetic ointment, so as to bring out an eruption as soon as possible, of great value in cases of this kind. Above all things, take care to relieve the symptoms by prompt and decided measures before the stage of paralysis comes on, for when this arrives, I believe you can do very little in the way of cure. I have seen three cases in which, after the usual depletions, the symptoms were relieved by bringing the patients rapidly under the use of mercury; and I think local inflammation of the brain may be treated by mercury as well as localised inflammation of other parts. My late lamented friend, Dr. Leahy, communicated to me the particulars of two cases in which pain, spasms, and other symptoms of a local encephalitis were present, and in which complete relief was obtained as soon as mercurial action was brought on. I recollect an old lady who got pain in the right side of the head, with contraction of the fingers of the left hand, and alternate flexions and contractions of the fore-arm, accompanied by slight lesion of the intellectual functions. She was

leeches three or four times, blistered, and purged, without any decided relief. I then determined to try the effect of calomel, and was gratified to find that, according as her mouth became affected, the pain and contraction of the fingers, as well as the motions of the fore-arm, diminished considerably, and as soon as full ptialism was established all her symptoms disappeared. This case is particularly interesting, inasmuch as it shows that the ordinary treatment by leeching, counter-irritation, and purging, failed in giving relief, so that we are justified in attributing some value to the use of mercury. In the advanced stages of this disease, it seems right to employ a seton in the back of the neck; and I would advise all who have been attacked to continue the use of this remedy for a great length of time.

The term *ramollissement*, or softening of the brain, is one which is very extensively used, and I fear often without any precise idea of its meaning. In ninety-nine cases out of a hundred this *ramollissement* will be found to depend upon local inflammation of the brain; of this I do not entertain the slightest doubt. I think we may very safely consider it as analogous to the softening of the lungs, liver, or spleen, or from inflammation of their texture. There is a peculiar softening of the brain in old persons, which we cannot connect with actual inflammation, but in all cases in the child, and in almost every case in the adult, *ramollissement* of the brain will be found to depend on inflammation. I do not mean to infer from this that it is in our power to cure every case of softening of the brain, for when it once sets in, the great probability is that the texture of the affected part is destroyed; but we can cure many cases by subduing the inflammation from which it derives its origin. Of course we cannot expect to accomplish this in the case of old persons, where the symptoms come on without any inflammatory phenomena, as in that peculiar softening of the brain, which forms the subject of Rostan's work, and occurs in persons beyond the age of seventy. This appears to be a species of senile gangrene. That form of *ramollissement*, which occurs in adults and children, is, however, very different from this, being, in the vast majority of cases, the result of inflammation. You will hardly ever dissect a case of partial encephalitis in the adult, or of hydrocephalus in the child, without finding more or less of this inflammatory softening.

CLINICAL LECTURES ON SURGERY,
DELIVERED AT
THE HOTEL DIEU, PARIS,
BY BARON DUPUYTREN,
PRINCIPAL SURGEON OF THAT HOSPITAL.
Corrected by himself.

Hypogastric Operation—Dangerous effects of—Increased danger from a Perineal Incision—Different opinions on—Introduction of a Catheter—Injurious effects of closing the Wound—Importance of Position—Case for the Operation—Symptoms of—Enormous Calculus weighing two pounds and a half—Cure—Latexal Operation—Bilateral Operation—Improvement of Instruments, &c., &c.

GENTLEMEN,—In my last lecture I gave you an anatomical description of the parts concerned in the different operations for cystotomy, and endeavoured to impress upon your minds the great importance of a correct knowledge of these parts.

I shall now direct your attention to the hypogastric operation. This must not be indiscriminately employed in all cases or without exception of age, sex, and constitution, or without considering the size of the calculus, &c., &c. We ought only to have recourse to it in cases in which the tuberosities of the ischium approach each other, in the presence of tumours at the inferior strait of the pelvis, or from the great volume of the calculus, in which the perineal operation is difficult, or even impracticable. In support of my opinion I will mention the fact that Côme in operating on eighty-four individuals above the pubes, in whom age, sex, situation, and health were different, stated that more than one of four of the patients, thus operated on, perished. This result is much less favourable, than by performing the subpubic operation indiscriminately, as in the cases of Côme among infants, women, adults, and old people.

As to the instruments and to the proceedings practised in this operation, all I believe have their real advantages, but I am far from thinking that they tend to lessen the danger of this operation. Also in my theses in 1812 for the chair of surgery, vacant by the death of Sabatier, I have stated, that incisions made in the perinæum, and neck of the bladder, add to the danger of the hypogastric operation; and more recently I have discovered that a sound placed in the bladder, either through the medium of the perinæum or urethra, increased the inconveniences and dangers of this operation, unless from well-marked symptoms, it was indicated to produce the re-union of the divided parts.

These two opinions have for some time been the subject of dispute among surgeons; one

party sustaining that a small incision made in the perinæum, instead of increasing the danger of the operation, facilitates the manœuvre of the *sonde à dard*, which they contend is indispensably necessary in the operation above the pubes; they pretend that this incision, by bordering the most inclined part of the bladder, presents an easy passage for the discharge of urine, and thus detracts it from the opening made in the lower part of the abdomen.

Amongst these objections, those who persist in saying that an incision in the perinæum and neck of the bladder does not render the operation more dangerous, must fall by the results obtained from the lateral operation, which, considering age, season, and other circumstances, is death to about one individual out of five or six. Now what is the opening made in the perinæum in the hypogastric operation, if it is not the lateral incision made in lithotomy? It might be vainly said that the incision, from being less extensive, was less dangerous; but from experience we well know that it is not from the extent of incision, that danger is to be apprehended.

The objection drawn from the facility acquired by the incision, in introducing and making the manœuvres with the catheter, is a little more plausible. In fact, we cannot deny, in admitting that the *sonde à dard* is indispensable, that it is not facilitated by making an incision in the perinæum. But we can make use of the *sonde à dard*, by introducing it into the urethra, and thus I frequently have made use of it on the living. For this purpose it is necessary to form a greater curvature with the sound, and after its introduction into the bladder, to bear downwards its extremity, which is easily allowed from the flexibility of the urethra; besides, the *sonde à dard* is indispensable in this operation.

As to the facility afforded from incision in perinæo to the discharge of urine, I consider that the introduction of a catheter by the urethra would be much more advantageous and less dangerous. But the opinion entertained, that either a catheter, or an incision in the perinæum, prevents the urine from flowing through the wound made above the pubis, is merely supposition, and is daily contradicted by experience. In fact, whatever may be the extent or length of the wound made in the perinæum, or whatever may be the calibre of the catheter introduced into the urethra, we never find the urine completely abstracted from the hypogastric incision, but is discharged in part through both these apertures, which fact is well known to all practical surgeons. It appears, that whenever the bladder is incised near the extremity of its body, towards this point all the contractions of the organ are directed, and the urine in consequence is expelled through it. I have also for a long time regarded as useless all the precautions taken to prevent the flow of urine through this new incised orifice. I may go still further; I believe all attempts to

retard the flow of urine through this passage, such as drawing the edges of the wound together, compression, and other analogous means are dangerous. I believe them likely to cause urinal infiltrations, and thus produce peritoneal inflammation, or inflammation of the cellular tissue in the pelvic cavity, the two most dangerous symptoms that can arise from cystotomy. The best method we can adopt, then, after performing the operation, is to keep the edges separated by means of lint, a band on the wound, and allow by position the parts to be in a state of relaxation. The following case will demonstrate to you the method of proceeding in the operation, and will furnish to you the application of the general considerations of which I have been speaking.

CASE II.—M. R., sixty years of age, an architect, of middle stature, sanguineous temperament, and good constitution, had been accustomed to tedious occupation, lived well, and partook of generous wines; had been troubled for a long time with frequent desires to pass his urine; great difficulty in making water, and when this was effected, he suffered from vivid pains. These symptoms had been accompanied with hæmaturia for ten years, especially after walking or riding in a carriage a long distance, from excess of professional occupation, or luxuriant living.

For two years all the symptoms had become aggravated; the discharge of urine was almost continual, and involuntary, and he had constantly suffered from pain in the hypogastric region, and in the perinæum. A surgeon sounded him at this period, but found no stone; a year afterwards, another surgeon announced the existence of a catarrhal affection of the bladder, and prescribed a treatment improper for the former affection.

The health of the patient, however, daily grew worse. The discharge of urine took place only by drops, in spite of the greatest efforts and the most excruciating pains. Wearied by such excessive and continual suffering, he was confined to his bed; a slow fever supervened, and rapid emaciation ensued. His urine at this time imparted a strong ammoniacal odour, and appeared to be formed by a mixture of blood, pus, and morbid mucosities. In the year 1824 I was called to see him at Chantilly, and such was his condition when I visited him. I immediately conjectured that the symptoms arose from calculus in the bladder, and that the stone was either voluminous or engaged in this organ. Upon sounding the patient, before the point of the instrument had entered the bladder it struck against a calculus. I endeavoured to make the instrument penetrate further in the cavity of this organ, but succeeded only slightly, and that with difficulty. The sound, placed between the foreign body and the wall of the bladder, appeared pressed, as if with a vice; I withdrew it, and introduced my finger into the rectum, and found the

lower fundus of the bladder filled, dilated, and hardened, from the presence of a foreign body. I then flexed the trunk, examined the hypogastrium, and recognised behind the pubis, below the linea alba, a hard, voluminous, resistant body; by placing my indicator finger in the rectum, and by applying my other hand on the hypogastrium, I could raise and depress alternately this foreign body, and feel it with each hand at the same moment. From the immense volume of the stone, I at once determined to perform the hypogastric operation.

I immediately communicated to the patient the existence of a stone in the bladder, and told him that all the symptoms he had so long been tormented with originated from its existence. The patient immediately implored me to operate, and free him from such an enemy. I prescribed a bath for him, and a gentle purgative; and, the following afternoon, I went to perform the operation, and was accompanied by my colleagues, MM. Sanson, Lemaire, Marc, and by M. Louge, who assisted me in the operation.

The pubes were shaved, the patient placed on a bed, and an examination, both by the rectum and hypogastrium, was again made. The result of this examination confirmed the opinion I had made the previous evening. I then placed myself to the right side of the patient, and introduced a common silver catheter, which was arrested, as in my previous examination, by the stone being placed opposite to the neck of the bladder. An injection was used through the catheter, in the hope of dilating the neck of this organ, so as to enter into its cavity and distend it, but the injected fluid immediately returned. I then substituted the *sonde à dard*, but without effecting my object. Finding I could neither distend the bladder by injection, nor pass the sound between the stone and strongly contracted walls of the bladder, I at once proceeded to perform the operation.

The legs of the patient were flexed upon the thighs, and the latter upon the abdomen. M. Sanson introduced his finger into the rectum, and raised the stone, so as to project it as much as possible above the symphysis pubis. I then made an incision, in the direction of the median line towards the umbilicus, about four inches in extent, cutting through the skin, cellular tissue, and a deep bed of fat, which is always found in this region. The aponeuroses of the abdominal muscles were now exposed, which I next incised. The pyramidal muscles are separated by the recti; but from the power of their contraction, one pressing against the other, I divided the fibres of each to the extent of a few lines in a transverse direction. I was able by passing my finger between them to feel the stone, which was much facilitated by M. Sanson pushing it forward with his finger. I next placed the ulnar side of the cubital finger of my left hand on the

symphysis pubis, glided the point of a sharp bistoury over the angle of this finger with my right hand, and plunged it into the anterior part of the body of the bladder, directly behind the symphysis pubis. Some thick, white, inodorous pus escaped from the wound immediately. This at first I believed to come from an abscess situated either in the neighbouring cellular tissue of the bladder, or in its parietes; but, the point of the bistoury coming in contact with the stone, I was sure that it had entered the bladder. I then increased the opening from below upwards to the extent of five or six lines; my finger, which directed the instrument, followed its point, and penetrated the bladder with it. I now found that the walls of this organ were half an inch in thickness, and that its cavity was filled by an enormous calculus; and not without satisfaction I found there existed an interval of full two inches between the most raised point of the incision and the superior part of the bladder, and that the peritoneum did not extend so far down as ordinary. I then increased my incision upwards with a blunt pointed bistoury.

I now was able to proceed with the extraction of the calculus, which appeared from its mass, form, and from the contractions of the bladder, to be fixed in the centre of the pelvis. Taking a pair of forceps, and separating the branches, I passed one on each side of the stone, again reunited them, and thus caused the foreign body to move from right to left, and from below upwards, and by degrees effected its extraction. The form of the calculus exactly corresponded to that of the bladder, the cavity of which it had entirely filled; large and wide at the inferior part, and presented three lobes, two of which were situated on the sides, and the third on the posterior part of the fundus of this organ; along the sides of the stone were two grooves, divided by a prominent ridge, produced by the passage of urine passing from the ureters to the urethra; above, the stone terminated in a blunt cone, answering to the summit of the bladder. Its length was three inches and a half; its width three inches, and its thickness two inches and a half.

The stone was immediately weighed by M. Lemaire, and found to be two pounds six ounces and a half, composed of the ammoniaco-magnesian phosphate.

After the extraction of the stone, I passed an emollient injection into the bladder; this immediately escaped through the wound.

My after treatment was very simple. I allowed the patient to lie upon his back, kept his legs in a slight state of flexion, by means of a bolster placed under the hams, introduced lint between the divided edges of the wound, and applied over the incised part linen besmeared with cerate, and over this dressing some pieces of lint. I did not introduce into the urethra or through the wound a catheter, neither had I recourse to any means to pro-

mote adhesion. His stomach was covered with flannels imbibed in an emollient decoction, and I prescribed for him a simple decoction from the root of couch grass (*chientent*) with some gummy syrup.

The patient was now relieved from pain, which for some years he had suffered from, and soon after the operation fell asleep.

In the evening the abdomen became painful; shiverings succeeded by heat, and fever supervened, without hiccup or vomiting. He was bled copiously from the arm, and the urine passed freely from the wound.

The next morning the patient was much better, still the pulse continued strong and full, and there remained slight pain about the abdomen. Another bleeding was had recourse to; the dressings were frequently replenished.

Suppuration of an abundant and healthy nature commenced on the fourth and fifth days; the dressings night and morning were changed; the urine continued to flow through the wound.

The urine now passed partly through the wound and partly through the urethra, the extent of the incision diminished, and the suppuration decreased in quantity. Every day his appetite improved, his strength and spirits returned, and in about a month he was completely cured.

From this time the patient enjoyed perfect health, but occasionally was troubled with a slight catarrhal affection of the bladder, which immediately subsided by the administration of emollients.

This case points out to you the manœuvres necessary for this operation, and it remains only necessary for me to describe the process I use when about to perform the operation. 1st. If I think the hypogastric operation required, I perform it at once, without considering it the most unsuccessful. 2nd. When performing it, I condemn altogether the incision in the perinæum, or the introduction of the catheter immediately afterwards; but should I, during the progress of cure, think the latter required, I have recourse to it. In some cases I have found the introduction of an elastic gum catheter beneficial.

Lateral operation.—In my last lecture I mentioned to you the particulars of this operation, and the success generally attending it, from which you will perceive that the danger is not much less than in the preceding. The numerous works that have been written on this subject by men of the highest merit, in order to replace it by other proceedings, is a sufficient proof of the inconvenience presented by this operation.

From my own experience I felt convinced that the operation would be advantageously modified, by incising the neck of the bladder, in the direction of the symphysis pubis. In the year 1816 for the first time I performed the operation in this way, using the same instruments as in the lateral operation, with the addition of the blunt pointed bistoury.

The patient was bound and placed in the ordinary position for lithotomy. A catheter, grooved on its posterior surface, was passed into the bladder, and retained by an assistant, who at the same time carefully raised the scrotum so as to keep the catheter in a perpendicular direction. With a common bistoury an incision of about eighteen lines in length was made in the direction of the raphe of the perinæum, the commencement of the incision being about two inches and a half from the anus, and its termination nearly an inch from this opening. By the next incision, which was made parallel to the first, the bulbo-cavernous muscles, and the cellular tissue filling the space between the bulb and the urethra before, and the rectum behind, were divided: the membranous portion of the urethra was now exposed. The third incision divided the whole extent of this portion of the urethra, from the bulb before to the verumontanum posteriorly. The *lithotome* being introduced along the groove in the catheter, the latter was withdrawn, and the cutting edge of the former directed upwards and forwards towards the symphysis pubis; the handle of the instrument was now passed downwards, and withdrawn in this direction, thus dividing by this first incision the neck and inferior anterior part of the body of the bladder, and carrying the incision to the extent required. By this means, you observe, you are enabled to make any length of incision you may think necessary.

From this operation there results a triangular wound, the apex of which corresponds to the anterior and inferior part of the body of the bladder, and the base to the surface of the perinæum or external part of the incision. The anterior side extends obliquely from the anterior angle of the first incision, or from the external incision to the anterior or inferior part of the bladder, in traversing the space which separates this latter organ from the symphysis pubis, and passing between the anterior ligaments of the first.

We have, then, in the course indicated, proceeding from below upwards, the skin, bulbo-cavernous muscles, bulb of the urethra, subpubic ligament, symphysis pubis, and anterior ligaments of the bladder, and, corresponding to these different parts, cellular and vascular tissue. The posterior side extends from the space comprised between the posterior angle and external incision and the anterior and inferior part of the bladder. The anatomical parts to be noticed from one of these points to the other, are, if we proceed again from below upwards, skin, cellular tissue, muscular plane, resulting from the union and interlacement of the external sphincter, bulbo-cavernous, and transverse muscles; inferior part of the prostate gland, and prostatic portion of the urethra, posterior part of the meatus urinarius, superior portion of the neck of the bladder, of the prostate, and inferior and anterior part of this organ; all parts cut through

in lithotomy, with the exception of the inferior part of the prostate gland and the wall of the urethra which corresponds to it. Very near the centre of the wound is seen the membranous portion of the urethra, the superior and anterior walls of which are at the same time divided. The calculus, when being extracted, has to pass the first opening, the direction of which is nearly vertical, and corresponds to the neck and anterior and inferior part of the body of the bladder: the second, which is slightly oblique upwards and backwards, like the membranous portion of the urethra to which it belongs, and the third horizontal, corresponding to the skin of the perinæum. Then, after making the incision as I have pointed out to you, it remains only, if the stone be of small size, to grasp and extract it in the ordinary way.

Such, gentlemen, is the proceeding that I have substituted in the lateral operation of lithotomy. I first attempted this operation in 1816, on a patient eighteen years of age, in the house of M. Cartier; it was followed by the most speedy and happy success. Nevertheless, in 1824, I thought it better to substitute simple lithotomy for the operation called double. In this new proceeding, the incision made by this instrument is directed to the right and to the left: also transversely. This operation was performed at the Hôtel Dieu on the 24th of April, 1824.

CASE III. — Alexander Patrix, an infant, five years and a half old, of good constitution, had been for three years affected with stone. The operation that I have just described was performed with the greatest facility, and the stone extracted was nearly of the form and size of a small almond; scarcely any hæmorrhage occurred. For the first few days after the operation the patient complained of slight pains in the hypogastric region, which subsided to leeches, baths, and emollient fomentations. The pains, however, again re-appeared, and existed particularly in the abdomen; his tongue was slightly red at the edges. I had some mercurial ointment spread on linen and applied to the abdominal region. Two baths were administered: also injections composed of decoction of poppy heads were given. The pains continuing obstinate, twelve leeches were applied to the hypogastric region, after which no traces of intestinal irritation remained. On the third day succeeding the operation the urine was discharged by drops through the wound; by the fifth, the prepuce became slightly œdematous; and by the tenth, the œdema had extended to the scrotum; resolutives were applied on these parts; the infiltration continued till the eighteenth day, when it suddenly disappeared, and the urine took its natural passage. On the 19th of May, twenty days after the operation, the infant left the hospital perfectly cured.

Foreign Medicine.

Note of the Post Mortem Examination of a Female who committed Suicide almost immediately after Coitus.

BY H. BOND, M.D., OF PHILADELPHIA.

[We insert an accurate report of this case, as it was garbled by a contemporary, and pirated without acknowledgment. So far as it goes it is valuable but the conditions of the vagina, os uteri, and orifices of the uterine tubes are omitted, and leave the narrative unsatisfactory.—Eds.]

In May, 1827, I was invited by Dr. Samuel Tucker to examine, post mortem, the body of a female who had destroyed herself with laudanum. She was apparently between eighteen and twenty years of age, well formed, and in good health. She passed a night, or the most of it, in coitu with a young man, and before morning swallowed a large quantity of laudanum. Dr. Tucker was called to her in the course of the morning, but so late that all his efforts to restore her were ineffectual. The body was opened the next morning in the presence of Drs. Tucker and Meigs. Neither the head nor chest were opened. The viscera of the abdomen, as far as they were examined, exhibited no mark of disease, but the odour of laudanum was very strong in the stomach. I removed the internal organs of generation, and took them home for examination.

The uterus was larger than I had ever before seen it when healthy and unimpregnated, and its colour indicated more vascularity. The ovaries were large, extremely vascular, and situated nearer the uterus than usual. Instead of hanging loose at the distance of an inch or more, they appeared to be drawn so close to the sides of the uterus, that there was scarcely the space of a quarter of an inch between them. The Fallopian tubes were very vascular, so much so as to give them a firmer and more fleshy appearance than usual, and instead of ending in loose, floating fimbriæ, appeared to terminate by a union with the ovaries, and to be very tortuous on account of the short distance between the ovaries and the origin of the tubes. On the surface of the ovaries were seen a few small vesicles of the size of shot, projecting little or none beyond the surface of the gland, and

containing a slightly turbid fluid. From the ovaries and the fimbriæ several small vesicles were seen hanging by extremely delicate pedicles, from one-fourth to seven-eighths of an inch in length. They looked like pyriform drops of mucus, a little larger than the seeds of grapes, covered with an extremely delicate pellicle, which appeared to constitute the fibrils by which they were suspended. Upon cutting open the uterus, it was found to be thickly coated with a substance having the appearance and the strong peculiar odour of semen. Some of this substance was in the neck of the uterus. The Fallopian tubes (at least the one which was laid open) contained apparently the same matter, but whether it possessed the seminal odour was not ascertained. Upon wiping this matter from the lining membrane of the uterus, it was found to be of a vivid red, as red as the conjunctiva in acute ophthalmia, or as if it had been injected with vermilion.—*American Journal of the Medical Sciences.*

Hydrocyanic Æther.

At the sitting of the Académie des Sciences on the 26th of May last, M. Pelouge made a few remarks on this æther, which he had discovered by the action of heat on a mixture of the sulfovinate of baryta, and the cyanuret of potassium. This substance is colourless, inflammable, and boils at 82°, under atmospheric pressure of a density equal to 0.787 at the temperature of 15°, slightly soluble in water, and mixes with alcohol and sulphuric æther in all proportions. It does not precipitate nitrate of silver, in this respect resembling the hydrochloric æther, which decomposes this salt, after having been previously destroyed by the action of heat.

M. Pelouge considers the hydrocyanic æther is formed of equal parts of olefiant gas and Prussic acid vapour.

Case of Fatal Hæmorrhage, occasioned by rupture of a Varicose Vein during Parturition.

BY M. STENDEL, ESSINGTON.

A woman, about 30 years of age, mother of two children, remarked, towards the latter period of her third pregnancy, a soft tumour projecting from the vagina, which the midwife who attended her stated to be a large pur-

pureal varicose tumour (*hémorroides*) and for which she recommended blood-letting. This plan of treatment was adopted, and the tumour diminished, but did not disappear; soon after it again increased in volume. The woman's health continued good; and, though I was attending one of her children, she mentioned not a word of it to me. The labour proceeded naturally; but, as soon as the head reached the cavity of the pelvis, the tumour became ruptured, and discharged, as well as I could judge, about seven or eight pounds of blood. The patient became weak, extremities cold, and she was insensible. I was immediately sent for, and arrived with an accoucheur. All our attempts to return life were useless. The varicose sac was sufficiently large to admit the fist, and hung from the vagina. The infant was extracted from the mother, but was dead.

Her friends would not permit a post mortem examination. Had the varicose tumour its origin in the uterus or vagina?—The latter appears most probable, or else rupture would have sooner taken place from the contraction of the uterus.

What ought the practice to be in a similar case before delivery? Would it be necessary to open a tumour of this size, and secure it by ligature before parturition? This could be practised only when the tumour originated from the vagina. Or should we endeavour to diminish it by the application of leeches and cold? Which method should be adopted, I shall leave practitioners to decide.

[We have lately treated a case of this kind in a lady of full habit, whose veins were varicose; a tumour of the enlarged veins, attended with violent pain, was on the outer surface of the leg, between the heads of the tibia and fibula. The patient, who was in the seventh month of pregnancy, was ordered to remain in the horizontal posture, so as to take off the pressure of the gravid uterus from the pelvic and abdominal veins, and facilitate the return of the blood through the inferior extremities: a piece of lint, moistened with camphorated oil and laudanum, was loosely applied over the tumour, and in a few days a bandage. By these means the tumour was removed, and the patient is now in the eighth month of pregnancy.—Eds.]

Reviews.

A Practical Treatise on Medical Jurisprudence, with so much of Anatomy, Physiology, Pathology, and the Practice of Medicine and Surgery, as are essential to be known by Members of Parliament, Lawyers, Coroners, Magistrates, Officers in the Army and Navy, and Private Gentlemen; and all the Laws relating to Medical Practitioners. With Explanatory Plates.
By J. CURRY, Esq., Barrister at Law.

THE author of this work is well known to the legal profession as a laborious and useful writer, and now comes before the public in a new capacity, as a compiler of medical sciences, and of all the laws relating to the practice of the medical profession. The object of the author is to present lawyers and all others concerned with the administration of justice, with a condensed practical view of anatomy, physiology, pathology, surgery, chemistry, medicine, medical jurisprudence and police; and to medical men so much of the law connected with their departments as ought to be intimately known by them, and especially all the laws relating to their own rights, privileges, conduct, duties, and liabilities. He very properly remarks—

“A general knowledge of these subjects is essential to the perfect education of all officers in the army and navy, and of every gentleman, and especially so to legislators, judges, coroners, magistrates, barristers, and indeed to every member of the legal profession, and to all persons who may become jurors or witnesses; so as to enable legislators more scientifically and practically to determine upon the expediency of improving the existing laws relating to public health, and the protection of the persons of individuals, and all to give due effect to the existing regulations. By a knowledge of these subjects, the present laws will be better understood and applied, and preferable enactments with regard to the preservation of health and police and punishments may be introduced. That science is of primary importance which most conduces to the perfect and permanent happiness of mankind; theology and moral philosophy, as calculated to insure future as well as present mental happiness, stand pre-eminent; but the

next in substantial and universal importance, are physiology, pathology, and surgery, since these tend to improve or secure health and happiness, or to restore them when afflicted by corporeal or mental disorder.”

We fully agree with the author in these sentiments, and have in our work on medical jurisprudence expressed them; and we were highly gratified at the appointment of Mr. Warburton's committee on medical education, as the publication of the voluminous evidence given before that body cannot fail to interest many legislators, and raise the importance of medical science in their estimation. The bane of our profession has been the mystery in which it has been kept, and the utter ignorance of the public about it. The work before us is also well calculated to afford lawyers, judges, jurors, witnesses, officers of the army and navy, an outline of the medical sciences and practice. Our readers will, no doubt, be very much surprised at the following extract, which gives an outline of the division and arrangement adopted by Mr. Chitty, a gentleman who, so far as we know, is not a member of our profession.

“The first part of the work, after explaining technical terms, and referring to the sources of information, proceeds to describe the structure of man in the healthy state, and which comprises anatomy and physiology. At the same time are in general noticed the principal diseases affecting each organ or function. The component parts, whether fluid or solid, and the divisions into organs and functions, and certain general properties are first considered. Then is taken an anatomical and physiological view of every organ and of each function in particular. The bones, joints, ligaments, muscles, tendons, arteries, capillaries, veins, absorbent and seccernent vessels, and nerves, and all other parts, are separately examined. Then are described all the functions, whether of motion, respiration, circulation, digestion, absorption, or secretion. The brain and its parts, the nerves, the entire nervous system, and the organs of the external senses, are fully considered. An attempt has been made concisely to examine the temper, passions, and emotions, and the intellectual faculties, and to show that the latter are capable of enlargement and improvement, even hereditarily, by due mental exercise and attention; and it has been shown that certain mental

diseases and injuries are capable of medical or philosophical relief beyond our present experience; and that injuries to the mental faculties ought to be the direct objects of legal regulation, though at present many are only subject to censure.

"Then follows a description of the function of generation, and of the principal distinguishing peculiarities between the sexes, and the progress of the foetus, and all circumstances that may tend to explain the too numerous offences connected with miscarriage, abortion, premature birth, infanticide, and concealment of birth, and to show the inexpediency of some parts of the existing law.

"Then are considered the integuments or external covering of the whole frame, including the three skins, and the hair and nails, with an account of the principal diseases and injuries to which they are subject.

"Then is taken a medical and legal view of the different ages, with their physical and legal differences, incidents, and consequences. Lastly is given an outline of the circumstances to be observed medically, as well as legally, to secure health and happiness, whether bodily or mental."

The descriptive part is illustrated by numerous plates, front and back views of the skeleton, action of the biceps muscle, trachea and lungs, heart and large vessels, entire and opened, the viscera of the chest and abdomen, phrenological organs, base of the brain, eye, ear, and pelvis.

The greater portion of the part before us is purely medical, and is compiled from the best of our national works on anatomy, physiology, &c., with copious references. We cannot help thinking that several physicians and surgeons must have associated to arrange and condense the information on the medical sciences; for we feel convinced that a barrister could not have executed the work, however learned he might be. There is one serious defect throughout the work, and that is, that most of the recent opinions of continental medical writers are entirely omitted, and many erroneous and obsolete notions left uncorrected. This accusation can be amply attested by the article on the generative organs and functions, which is extremely superficial, and on many points antiquated. We shall prove the justice of this stricture before we have done. We are ready to admit that the work is of great value

to lawyers and those for whom it is intended; but it will not be referred to by medical students or practitioners, who must be acquainted with the principles described in it. The greatest part of the medical works quoted are text books in the hands of students, and consequently their contents cannot present any features of novelty. There is another defect in this treatise, the omission of reference to the majority of the latest continental works.

The second part of the work is to be devoted to the consideration of pathology and surgery, including an account of all medical and surgical disorders and diseases, and their remedies.

The third part will contain the laws relating to public health, police, to injuries, to crimes and punishments, with a comprehensive view of medical jurisprudence, police, and evidence, and laws on insurances for lives and properties.

The fourth part is to embrace the laws relating to the members of the medical profession, their rights, privileges, duties, and liabilities; to dentists, cuppers, accoucheurs (obstetricians), midwives, nurses, chemists, druggists, and herbalists, sale of medicines, &c.

The fifth part is to be on medical evidence.

It appears to us that the author proposes to occupy five volumes, royal octavo, and if each be published at a guinea, the circulation must be very limited. The work will be the most comprehensive in our language, and will be one of reference and authority. It must be interesting to barristers, coroners, magistrates, jurors, witnesses, military and naval officers, private gentlemen, and, so far as the legal part is concerned, to the medical profession. Had the author committed this part to the management of physicians and surgeons, and followed the example of Dr. Paris and Mr. Fonblanque, he would have produced the best work on the subject of which he treats. We consider it as impolitic in a barrister to attempt to instruct medical practitioners, as in a physician or surgeon to undertake the duty of writing a treatise on law. Few are so competent to expound the law as Mr. Chitty, and in this particular he has exceeded all his predecessors so far as he has gone. His account of the law on mental alienation is admirable. His account of the laws on idiocy, lunacy, insanity, and weakness of intellect, are luminous, and perhaps unparalleled. These occupy several pages, and are, in our opinion, the best executed portion of the work. We shall place

them before our readers in a future notice. The succeeding section is on the functions of generation and the laws relating to them; and here we must assume the unpleasant office of critics.

In p. 381, it is stated that the sexual ability exists only between the ages of 14 and 65 in the male, though it is well known that men of 70 have married and had children. There are recent instances afforded by two eminent members of our profession. Pliny informs us, that Cornelia, one of the family of the Scipios, gave birth to Valerius Saturninus at the age of 62. Valescus of Tarentum attended a woman in labour at the age of 67. Haller mentions the case of a woman who was delivered at the age of 63, and another at the age of 70. In all these cases the women menstruated regularly, and were not liable to greater inconveniences than during the ordinary age of fecundity. Now, this is a point of great importance, as it influences judges in disposing of property. A case was tried in the Court of Chancery in May, 1833; a large property was in dispute, and the question to be determined was, could a woman of 60 years of age be a mother. Sir William Horne, then Attorney-General, argued that there was no such case on record, and that if credible evidence could be produced in proof of it, he would give up the cause of his client. As no such evidence was produced he succeeded.

It is not correct to limit the period of fecundity in man to the age of 65, as there are many cases which prove the contrary. The case of Thomas Parr is generally known. He remarried at the age of 102, and performed his conjugal duties so well at the age of 140 as to make him forget his old age. The case of De Longville, who had ten wives, and married at the age of 99, is in point. Many might be quoted from the sacred volume; so that there is by no means sufficient proof for limiting the fecundity of either sex to 54 or 65.

There are other faults in the article on generation. The account of the development of the embryo is antiquated, and no allusion is made to the researches and observations of MM. Velpeau and Breschet, though published last year, and the best on the subject.

The obsolete and erroneous notion of animate and inanimate foetuses is also entertained,

and the laws relating to abortion or stay of execution, based on it, are, as might be expected, very graphically described. We believe, however, that no physiologist exists, who is not convinced that the ovule or embryo is a living being from the moment of conception; and, of course, before the time of quickening, which is generally about the fourth month of utero-gestation. The spark of life is communicated at the moment of impregnation; for it would be unscientific and absurd to maintain that the foetus is not a living being until the time of quickening; and it would be, we apprehend, impossible to comprehend how life could be communicated at the fourth month, when dissection has enabled us to observe the embryo perfectly formed at two months and a half, supplied by blood from the parent, and its heart in action. If these are not better proofs of its vitality than the vague opinion that the foetus becomes a living being at the time of quickening, we are at a loss to know what are. If these be true, it is as great a crime to destroy a foetus or a pregnant woman before the period of quickening as after it, and, therefore, the law should be changed. Had Mr. Chitty been aware of these facts, we feel convinced he would have commented on the defective state of the law, and lead to its revision.

The next point, as to the evidence of an infant's having been born alive, is imperfectly considered. The author does not mention those cases in which infants were supposed to be born dead, and resuscitated after two hours, or the case in which the infant was laid aside as dead, the undertaker sent for, and life apparent at the expiration of twenty-four hours afterwards.

In pointing out these defects and omissions we are actuated by impartial criticism only; as we by no means wish to cavil about trifles, or to find fault with the whole volume. On the contrary, we consider the medical part of this work extremely well executed — most astonishingly so, if by a barrister, and one of great value to lawyers, judges, magistrates, coroners, private gentlemen, officers of the army and navy, and those who act as jurors or witnesses. The work deserves a place in every legal library, and is one from which the general reader will derive a vast fund of interesting and valuable information.

(To be continued.)

An Inquiry into the Nature of Sleep and Death, with a view to ascertain the more immediate Causes of Death, and the better Regulation of the Means of obviating them.
By A. P. W. PHILIP, M.D., F.R.S., &c.
London: Renshaw. 1834.

The contents of this volume are the results of experimental inquiries made by the author into the laws of the vital functions, a subject to which he has paid great attention for several years. The principal object the celebrated author had in view in making these experiments was, to determine the nature of sleep and death, and, by discovering the more immediate causes of the latter, to contribute to the better regulation of the means of preventing them. For as the functions of life depend on the powers of the nervous and muscular systems, and the relations these bear to each other, all rational systems of medicine must be founded upon them.

The knowledge we obtain of particular functions is acquired very slowly, and can only be the result of many minute and laborious investigations; and as particular laws can only be properly understood from an investigation of general ones, the author first applied himself to the consideration of the latter.

The fundamental error of physiologists who have considered this subject, has been their not taking the general laws of the animal frame into consideration; and, however valuable the particular facts ascertained by them may be, they are still defective on account of this neglect. Thus we have been taught that the heart and blood-vessels are placed beyond the immediate control of the nervous system, an error which has probably had more influence on the practice of medicine than any other into which we have been led by physiologists; and that the powers of the ganglionic system are independent of the brain and spinal marrow, together with other theories equally as erroneous; but to enter into the consideration of which would be at present foreign to our subject.

The author commences by observations on the general functions of the nervous system, and the relation which they bear to the other vital functions; and continues these observations on the effects of dividing the nerves of the lungs, and subjecting them to the influence of voltaic electricity; the functions of diges-

tion; the sources and nature of the powers of circulation; the relation subsisting between the nervous and muscular systems in the more perfect animals, and the nature of the influence by which it is maintained; and in this manner brings the reader to the more immediate subject of the work, namely, "The Nature of Sleep and Death."

There is probably no question relative to the living animal which involves a more general view of its phenomena than sleep, and none on the nature of which our opinions are more vague and unsatisfactory. We can discern no final cause of the alteration of watchfulness and sleep, but what has its source in the imperfection of our nature. Why certain organs are capable of constantly maintaining their functions, whilst others require intervals of repose, is perhaps what we shall never be able fully to ascertain; but there is no difficulty in perceiving the necessity of the former part of the arrangement, for the permanent functions are those on which the life of the animal immediately depends, the intervals of repose appertaining to those alone which are the means of intercourse with the world which surrounds him, and which, consequently, have no direct tendency to destroy life. The only change which takes place in the action of the muscles of respiration during sleep is, that in proportion as the sensibility is impaired they are excited less readily, and respiration is thus rendered less frequent, a more powerful application of the cause being required; the consequence of which is, that when they are excited the air is drawn in with greater force, and from this reason, as well as from the relaxation which is apt to take place during sleep in the neighbouring parts about the fauces, more particularly in an advanced state of life, arises the cause of snoring. The other changes which take place during sleep in the vital system are evidently the result of a diminution of the frequency of respiration. This necessarily produces a proportional decrease in the frequency of the pulse; the properties of the blood being less frequently renovated in the lungs, it less readily excites the heart and vessels, and the diminished force of circulation is necessarily attended with a diminished formation of secreted fluids. The state of the vital system influences, in its turn, the sensitive system, and in this manner sleep is

rendered more profound. During health no change takes place in the vital powers to prevent the perfect restoration of those functions by which the animal is again fitted for intercourse with the external world, for these powers are never impaired in sleep, but only less readily excited.

The states which precede the last act of dying, and sleep, the author observes, depend on a failure of function in the same organs. And the only evident difference of these two states is, that the one is a temporary, the other a final, failure; and it will appear that in the only death which can be strictly called natural, the state of the sensitive system, which immediately precedes death, differs from its state in sleep in no respect but in degree. We shall here quote the author's own words, in order that the reader may form an idea of the general style of the work.

"The natural death of the animal is the death of old age; and as this is the simplest form of death, it is that which I shall first consider. We shall find that the state which immediately precedes this death, and must consequently be considered as its cause, must, in the nature of things, differ from sleep in no other respect than the less vigorous state of the functions of both systems, and consequently that these states are identical; the greater or less general vigour making no difference in their nature.

"Now, as the death of old age arises from the gradual failure of those functions, it must necessarily take place at the time at which their vigour is most impaired. If the vital powers are still capable of restoring the sensitive system under the disadvantage of a diminished frequency of respiration, it is evident that, if their decay be gradual, nothing occurring suddenly to accelerate it, they cannot fail to maintain the functions of that system during the short time which intervenes before the recurrence of sleep again exposes them to the same difficulty. Their failure necessarily takes place at the time when their functions are most difficult. The death of old age, therefore, is literally the last sleep, uncharacterised by any peculiarity. The general languor of the functions in the last waking interval is attended with no peculiar suffering, and the last sleep commences with the usual grateful feelings of repose, the last feelings experienced;

for with what takes place after them, the feelings, being suspended, have no concern.

"The only difference between the last, and the sleep of former times, is, that the exhaustion of the sensitive system, which is at first, as in the latter case, only partial, (for in the beginning of that sleep the sleeper may be roused by more powerful stimulants than those which preceded it,) becomes in its continuance, in consequence of the failure of those powers which formerly restored the sensitive system, complete."

Dr. Philip's work is one of great interest, and will necessarily be a source of entertainment to all who peruse it.

SELF-SUPPORTING DISPENSARIES.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—Your leader of last week contains an extract from the Report of the Poor Law Commissioners, "embodying the result of their inquiries into the medical treatment of parish paupers." Some observations respecting this subject I shall reserve for another opportunity, my present object having reference to that part of the extract laudatory of Mr. Smith and his self-supporting dispensaries, and to your paragraph thereon, in which you promise "some observations on the dispensing system," including, I suppose, that of self-supporting dispensaries, "to certain attempts at establishing which your attention has been lately called."

Now, gentlemen, believing, as I do, that the principle of self-supporting dispensaries, if properly carried into effect, is capable of producing the most beneficial results, both to the public and to our profession, I should be sorry to see you fall into any error in consequence of an imperfect knowledge of the subject, particularly as I sincerely admire your straight-forward, manly defence of the honour and dignity of our body, and your unflinching assertion of our just rights. In accordance with the principles you profess, you cannot do better, as I think, than open your pages to a full and fair exposition of the various bearings of this interesting but complicated question. Hitherto, the public have been supplied with little more to form conclusions upon than garbled and one-sided

statements, in which failures have been carefully suppressed, and success greatly exaggerated, the parties making them having been more anxious to advance their own peculiar views, than to furnish correct and impartial information, of the necessity for obtaining which you will form some idea from the following observations.

I have now lying before me, a pamphlet, published in 1831, by a "Society for promoting the Objects of *the* Self-Supporting Dispensaries, established March 22, 1830," and which, from the distinguished names attached to it, seems entitled to more credit than, upon strict examination, proves to be the case. After many excellent remarks upon some of the causes of pauperism, and an exposition of the objects of self-supporting dispensaries, I find at page 11 of this publication the following passage:—"In order to show the progress which has already been made in effecting the objects contemplated by Mr. Smith's plan, the most satisfactory course will be to make extracts from the Reports of the Committees of Dispensaries already formed on it, and from other sources of evidence, not only at Southam, where the first dispensary was established, and is superintended by Mr. Smith, but at Atherstone, Coton, and Birmingham." Had this promise been fairly fulfilled, and the reports and regulations of the institutions then in existence given to the public, I should not probably have found it necessary to trouble you with this communication. But how has the society done this? —Why, they have given the *first* year's report of the Atherstone Dispensary of Jan. 1829, *excepting the financial* statement, and then merely informed us that the second year's report was *equally favourable*. I say nothing of the unusual course of giving the first year's report of an institution to prove its success when the second was in existence, but call upon the authors of the pamphlet to reconcile their account with the fact, that the surgeons received in the first year 80*l.* 11*s.* 3½*d.* for attending 765 patients, while in the second they had *less* by 11*l.* for upwards of 1200.

After an extract from a letter published in the Coventry Herald, by the chairman of the Atherstone Dispensary, in recommendation of such institutions, follows a certificate, dated 1827, from the visitor of the poor at Southam;

but although the Dispensary at that place must then have been in existence upwards of five years, we have *no report*, no account of the number of surgeons, or of the number and class of patients, and no treasurer's statement, all of which are necessary to the formation of a correct opinion. In page 17 I find some observations, said to have been made by the conductors of a dispensary at Coton, in a communication to Mr. Smith, in which, however, no information is given beyond the mere fact that "600 individuals have become free members;" but what those persons have paid, or what has been received by the surgeons, deponent sayeth not.

But the most extraordinary part of this pamphlet is yet to come, as the following extract and my comment thereon will show. "The first dispensary formed on *this plan* at Birmingham, was found to proceed so well, that two more have been subsequently established." In this passage it is evidently intended that the public should believe that *all* the institutions mentioned were founded upon Mr. Smith's plan, and that *all* have been equally successful. *Magna est veritas et prævalebit*. The *first* self-supporting dispensary formed in Birmingham was in 1828, and, as Mr. Smith well knows, was *not* formed upon *his plan*, but upon a very different one, proposed by my friend Mr. Sanders. This institution is still in existence, but Mr. Sanders having been over-ruled in his efforts to place it upon a sufficiently liberal footing, he left it in 1830, and established another, now flourishing beyond precedent. Another, also upon Mr. Sanders's plan, was formed in Deritend and Bordesley (two hamlets adjoining to Birmingham, and now contained within the limits of the borough) in 1830, and was in 1833 incorporated with the former, under the title of the "Birmingham and Deritend General Self-supporting Dispensary."

The only one founded upon Mr. Smith's plan was established in 1830, principally by the exertions of the indefatigable chairman of the Atherstone institution, who had then removed to this town, and the laws of which, with the slightest possible difference, are precisely those of the Atherstone Dispensary, as they appear in the pamphlet. This institution, which was called the "Duddeston, Nechells, and Aston Self-supporting Cha-

ritable and Parochial Dispensary," has totally failed; a bazaar was got up last year to raise money to pay off its debts, and it is now, *de facto*, defunct. Yet Mr. Smith, enacting the part of the unnatural mother in the judgment of Solomon, has, in a letter lately published in the Birmingham Journal, stoutly denied his paternity to the bantling now no more, while, in the before quoted paragraph, the living ones are claimed, by implication at least, as his own children!

In the latter part of the pamphlet it is further stated, that dispensaries have been established at Wellsbourne and Barford, at Rugby, Derby, and Burton-upon-Trent, but upon what plan we are not informed, neither is any part of their reports given.

I am anxious not to occupy too great a space in your valuable publication, and shall therefore conclude (for the present) by calling upon the author of the pamphlet, who ought to be in possession of the necessary documents, for a full and honest account of all institutions established under the name of Self-supporting Dispensaries. When this has been done, or failing its being done, I shall be prepared to resume the subject. In the meantime,

I remain, Gentlemen,

Your obedient servant,

J. AARON,

One of the Surgeons of the Birmingham and Deritend General Self-supporting Dispensary.

Birmingham, June 18th, 1834.

P.S.—If compatible with your arrangements, I should be glad if you would cause the foregoing statements to be laid before the Medical Reform Committee.

NEW LITHOTRITIC INSTRUMENT.

A new calculo-fractor has been invented by Mr. L'Estrange of Dublin, a plate and description of which will be found in our valued contemporary, the Dublin Journal of Medical and Chemical Science for July. The medal of the Royal Dublin Society was awarded for this instrument. Mr. Crampton, the surgeon-general, operated with it (June 4th) in the presence of surgeons Adams, Hargrave, and Smyly, with complete success. The celebrated operator exemplified the peculiar advantages

of the instrument, and was the first surgeon in Ireland who performed lithotrity, as recorded by us some months since.

THE

London Medical & Surgical Journal

Saturday, July 5, 1834.

SIR GILBERT BLANE.

ON Friday last, June 27, Sir Gilbert Blane, Bart., expired at the advanced age of 85.

Of this eminent physician and admirable man it may be said with truth—

"Posteritati narratus et traditus,
Superstes erit."

We regret we are unable at present to do justice to the memory of our deceased friend, by detailing the full extent of his public services for half a century. Their beneficial effects will be felt as long as the British navy shall float. We know of no example where a higher reputation has been achieved by the mere exercise of practical wisdom and sound good sense.

The following extract from a recent work by the most eloquent philosopher of our days*, relieves us from the necessity of attempting to explain, in our own words, the nature of these services.

"It is to such observation, reflected upon, however, and matured into a rational and scientific form by a mind deeply imbued with the best principles of sound philosophy, that we owe the practice of vaccination; a practice which has effectually subdued, in every country where it has been introduced, one of the most frightful scourges of the human race, and in some extirpated it altogether. Happily for us we know only by tradition the ravages of the small-pox, as it existed among us hardly more than a century ago, and as it would in a few years infallibly exist again, were the

* Discourse on the Study of Natural Philosophy. By Sir John Herschell, &c.

barriers which this practice, and that of inoculation, oppose to its progress abandoned. Hardly inferior to this terrible scourge on land, was, within the last seventy or eighty years, the scurvy at sea. The sufferings and destruction produced by this horrid disorder on board our ships when, as a matter of course, it broke out after a few months' voyage, seem now almost incredible. Deaths to the amount of eight or ten a-day in a moderate ship's company; bodies sewn up in hammocks and washing about the decks for want of strength and spirits on the part of the miserable survivors to cast them overboard; and every form of loathsome and excruciating misery of which the human frame is susceptible:—such are the pictures which the narratives of nautical adventure in those days continually offer*. At present the scurvy is almost completely eradicated in the navy, partly, no doubt, from increased and increasing attention to general cleanliness, comfort, and diet; but mainly from the constant use of a simple and palatable preventive, the acid of the lemon, served out in daily rations. If the gratitude of mankind be allowed on all hands to be the just meed of the philosophic physician, to whose discernment in seizing, and perseverance in forcing it on public notice we owe the great safeguard of infant life, it ought not to be denied to

* Journal of a Voyage to the South Seas, &c. &c., under the command of Commodore George Anson in 1740–44, by Pascoe Thomas, Lond. 1745. So tremendous were the ravages of scurvy, that, in the year 1726, Admiral Hosier sailed with seven ships of the line to the West Indies, and buried his ships' companies twice, and died himself in consequence of a broken heart. Dr. Johnson, in the year 1778, could describe a sea life in such terms as these:—‘As to the sailor, when you look down from the quarter deck to the space below, you see the utmost extremity of human misery,—such crowding, such filth, such stench!’ ‘A ship is a prison with the chance of being drowned; it is worse—worse in every respect—worse room, worse air, worse food, worse company!’ Smollet, who had personal experience of the horrors of a seafaring life in those days, gives a lively picture of them in his *Roderick Random*.”

those* whose skill and discrimination have thus strengthened the sinews of our most powerful arm, and obliterated one of the darkest features in the most glorious of all professions.”

* Lemon juice was known to be a remedy for scurvy far superior to all others 200 years ago, as appears by the writings of Woodall. His work is entitled “The Surgeon’s Mate, or Military and Domestic Medicine. By John Woodall, Master in Surgery, London, 1636,” pp. 165. In 1600, Commodore Lancaster sailed from England, with three other ships, for the Cape of Good Hope, on the 2nd of April, and arrived in Saldanha Bay on the 1st of August, the Commodore’s own ship being in perfect health, from the administration of three table-spoonfuls of lemon juice every morning to each of his men, whereas the other ships were so sickly as to be unmanageable for want of hands, and the commander was obliged to send men on board to take in their sails and hoist out their boats. (Purchas’s Pilgrim, vol. i. p. 149.) A Fellow of the College, and an eminent practitioner, in 1753 published a tract on sea scurvy, in which he adverts to the superior virtue of this medicine; and Mr. A. Baird, surgeon of the Hector sloop of war, states, that from what he had seen of its effects on board of that ship, he ‘thinks he shall not be accused of presumption, in pronouncing it, if properly administered, a *most infallible remedy*, both in the cure and prevention of scurvy.’ (Vide Trotter’s *Medicina Nautica*.) The precautions adopted by Captain Cook in his celebrated voyages, had fully demonstrated by their complete success the practicability of keeping scurvy under in the longest voyages, but a uniform system of prevention throughout the service was still deficient.

“It is to the representations of Dr. Blair and Sir Gilbert Blane, in their capacity of commissioners of the board for sick and wounded seamen in 1795, we believe, that its *systematic introduction into nautical diet*, by a general order of the Admiralty, is owing. The effect of this wise measure, (taken, of course, in conjunction with the general causes of improved health, may be estimated from the following facts:—In 1780, the number of

We have to add to the facts contained in this extract, all of which are to be found in an interesting pamphlet published by Sir Gilbert in 1830, that, so early as the year 1780, the first year of Sir Gilbert Blane's service as physician to the fleet on the windward station, he presented a memorial to the Admiralty, in which he stated the causes of disease to consist in—

1st. The neglect of cleanliness, ventilation, and dryness in the interior economy of ships.

2nd. The want of lemon or lime juice.

3rd. The abuse of spirituous liquors, as the habitual beverage of seamen.

4th. The want of adequate nourishment and comfort for the use of the sick and convalescent on board of their own ships.

5th. The want of proper bedding and of soap.

6th. The want of a gratuitous supply of medicines, as well as necessaries, to the surgeons, in order to enable them to cure as many as possible without sending them to hospitals.

7th. The defective regulation of hospitals.

We have given this long catalogue in order to show at what an early period the neglected condition of the navy attracted Sir Gilbert Blane's attention, and how vast an improvement was wrought under his auspices.

In consequence of the high opinion the government entertained of Sir Gilbert Blane's judgment, he was consulted on various public occasions connected with his profession, and, among the rest, was despatched to visit the troops during the fatal Walcheren expedition. On his re-

turn, the Prince of Wales conferred upon him the title of baronet. In the fifth volume of the Medical and Surgical Journal, of which this Journal is a continuation, we have given some further particulars of his public life.

turn, the Prince of Wales conferred upon him the title of baronet. In the fifth volume of the Medical and Surgical Journal, of which this Journal is a continuation, we have given some further particulars of his public life.

Sir Gilbert Blane was a Licentiate of the College of Physicians. From his rank in the profession, and sterling upright character, he was once happily called—"The President of the Licentiates," a designation in which we have reason to know he gloried. The honour of a Fellowship he would not cringe for, and refused to accept, as a favour, to the great abasement of a rival President.

In his public life we know of but one circumstance that caused him a moment's pain. Sir Gilbert Blane was attached to the household of the Duke of Clarence. Upon his Majesty's accession to the throne, an attempt was made—need we say in vain—to exclude the Licentiate from the Royal favour. Under his Majesty's express command, the Marshaller of the Royal Physicians was ordered to place Sir Gilbert Blane's name (which had been omitted) first on the list; but, by some trick of etiquette (for we presume this is the justification), Sir Henry Halford's occupies that post. Sir Gilbert Blane *longo proximus intervallo* to Sir Henry Halford!

Sir Gilbert Blane, in addition to his medical attainments, was a man of extensive and varied erudition: he was fond of observing and tracing—to use his own elegant paraphrase of Cicero*—"that subsidiary influence and mutual dependence by which all the arts, sciences, and professions have a reciprocal bearing on

* "Etenim omnes artes quæ ad humanitatem pertinent habent quoddam commune vinculum et quasi cognatione quædam inter se continentur."

each other, conspiring to bring about the greatest sum of human enjoyment, and affording a field of contemplation, in which cultivated, benevolent, patriotic, and pious minds delight to expatiate." He lived among great and powerful men, and preserved his simplicity; he won their esteem and commanded their interests for his benevolent purposes, without subserviency or sycophancy. He has left behind him an unsullied reputation.

Foreign Hospital Reports.

HÔTEL DIEU, AT MONTPELIER.

Fungus Hæmatodes—Amputation at the Shoulder-Joint—Instantaneous Death from the admission of Air into the Veins.

COMMUNICATED BY M. H. JOFFRE.

A MAN, about 30 years of age, came to the hospital for fungus hæmatodes, which occupied nearly the whole extent of the arm and fore-arm. The skin covering the tumour was very thin, and ruptured in some parts, hæmorrhage supervened, and the disease made rapid progress. Amputation at the shoulder-joint was proposed as the only means of saving the life of the patient. The operation was undertaken; and scarcely had the arm been detached from the body, when the patient suddenly expired; lightning could not have produced death more speedily. The vessels, as we usually find them in this disease, were enormously increased in calibre; nevertheless, not much hæmorrhage took place during the operation.

The surgeon, surprised at such an unexpected and unforeseen occurrence, had the body placed in water, in which he examined it before a number of spectators. On cutting into the heart, a gush of air escaped, which at once revealed to him the cause of death.

Strangulated Hernia successfully treated with the Extract of Belladonna.

BY M. FRANKEL.

A labourer, of good constitution, aged 42, was struck in the right hypochondrium with the pole of a carriage, which knocked him down. When brought to the hospital, his

countenance was pale, extremities cold, pulse small. He had nausea and vomiting; the ejected matter was mixed with mucus; acute pains in the region of the liver. In his right groin was an hernial tumour, caused by the blow he had received. I had him bled, ordered leeches and lotions to the affected part, and prescribed laxative injections. The pain in the right hypochondrium ceased, but the hernia offered to reduction an insurmountable resistance. The hypogastrium became swollen, stercoraceous vomiting supervened, constipation continued, and the patient became very irritable. I proposed the operation, which he obstinately refused. The cold applications were continued; and I had two ounces of the extract of belladonna, mixed with some marsh mallow ointment, rubbed on the hernial tumour and hypogastrium. The result of this application was extremely favourable, and the intensity of the symptoms soon diminished; the hernial tumour became softer and smaller, the vomitings ceased, and some fætid alvine dejections were passed. The hernia returned, and the patient soon recovered.

Since the above, I have treated six cases with the belladonna, all of which have terminated equally successfully.

HÔPITAL BEAUJON.

Scirrhus Hypertrophy of the Neck of the Uterus—Excision—Utero-Peritonitis—Cure.—Clinical remarks by MM. Marjolin and Blandin.

A woman, 30 years of age, a mantua-maker, of middle size, and sanguineo-lymphatic temperament, who had constantly enjoyed perfect health, was admitted into the above hospital, February 3rd, 1834, for an affection of the uterus. Catamenia regular, and in natural quantity; mother of three children.

For two years she has observed small warts, which came spontaneously about the genital organs; their appearance was not that of syphilis, and they speedily yielded to emollients. States that she has never had the venereal disease.

Her complaint appears from her statement to have originated fourteen months since, as at that time she first felt a sensation of heat and weight about the hypogastric region. These symptoms became so slight that she con-

sidered them of no consequence. In a few months, however, the heat returned, the sensation of weight became more intense; leucorrhœa, which she had suffered from childhood, was now much decreased in quantity; no bloody discharge; menstruation natural. The patient complains of itching, and internal pricking sensations, heat in passing her water, and frequent desire to evacuate her urine and fæces; pains in the loins and kidneys, which she finds extend to the internal part of the thighs, much increased when in the erect position or in walking, and are greatly relieved by repose in the recumbent position. Coition gives her much pain. The patient believed that she had a tumour growing from the uterus, and requested M. Blandin to extirpate it.

M. Blandin, determined to ascertain the state of the uterus and its appendages, first made an examination per vaginam, afterwards with the speculum. The parts surrounding the external organs appeared perfectly natural. The neck of the uterus was found low down in the vagina; this examination caused but little pain. There was a slight descent of the uterus, without a deviation of the body of this organ. The lips of the uterus were regular, hard, and resistant; the anterior more developed than the posterior; the neck of this organ appeared voluminous, and its texture firm; the orifice was transversely oval, and lined by some albuminous mucosities. The body of the uterus appeared of its natural volume.

The speculum verified the above state of the uterus. The constitution of the patient was good, but at times she experienced twitching pains about the stomach and bowels. All symptoms sufficiently proved the existence of a scirrhus hypertrophied condition of the neck of the uterus, and the operation for excision of this part was proposed, and performed on the 8th of February.

There is nothing particular in this operation; it was performed in the ordinary way. The patient was placed and kept in the same situation as in the operation for lithotomy. A speculum was introduced, and Museux pincers were applied to the neck of the uterus, which was drawn downwards as much as possible. The speculum was then with-

drawn, and another pair of Museux forceps were introduced in a manner opposite to the first; the external labia were widely separated, and the neck extended towards them. The operator was situated in front of the vulva, conducted along the palmar face of the left indicator finger, a convex bistoury, with which the neck was excised, without excavating entirely that portion of the neck which was embraced by the upper portion of the vagina, though sometimes this latter is necessary in consequence of the extent of lesion.

The patient manifested during the operation but slight pain, only a few drops of blood escaped, and said afterwards her suffering was very slight. She was put to bed; no unpleasant symptom occurred. Gummy julep, with the syrup of diacodium (poppy) was ordered, and fomentations were applied to the lower part of the abdomen.

Examination of the extirpated Neck.—Its texture was whitish; of a close fibrous texture; hard and resistant, having the exact appearance of scirrhus with hypertrophy.

10th. Since the operation the patient has been going on well; a very slight sanguineous discharge has been observed from the vagina; pulse rather accelerated; skin moist, of a natural temperature.

11th. Disturbed sleep; impatience; pulse 108, feeble; frequent desires to pass urine. Catheterism was employed, which gave exit to a few drops of water. Complaints of colicky pains about the abdomen. Twenty leeches were ordered to be applied to the epigastrium; cataplasms and emollient injections were prescribed; gum water, &c., &c.

13th. Pains diminished; skin hot and dry; tongue natural. Medicines continued.

15th. Yesterday pains about the lower part of the abdomen increased; somnolency; pulse 104, tolerably powerful; tensidity of the abdomen, for which a copious blood-letting was effected; other medicines continued. To-day she complains of dragging pains of the uterus; slight shivering; thirst; vomiting came on about 12 o'clock at night; great agitation; countenance pale; tongue red at the point; pain on pressure about the abdomen; pulse small, 116; skin natural. Fifteen leeches to be repeated on the abdomen; emollient fomentations; injections the same. Bath prepared

with decoction of linseed, in which she is to remain for two hours.

16th. Better; all the symptoms ameliorated.

The symptoms continued some days increasing, others diminishing; sometimes accompanied with vomiting, at others with acute cephalalgia; pains about the region of the uterus, bladder, and vagina; all of which symptoms were alleviated by the ordinary remedies. Mercurial frictions were applied on the abdomen, salivation was produced; after which remedy the symptoms lessened in frequency, and by the 31st of March, not quite two months from the operation, she felt so well, that she requested to be discharged, which was permitted her, on condition that she would for some time remain quiet, and abstain from all imprudences.

A conical cul-de-sac was felt in the vagina, also a smooth regular surface without induration, leaving a small central aperture. All discharge had ceased.

This case presents an example of severe utero-peritonitis supervening simple excision of the uterine neck.

All authors coincide that this is the most frequent and dangerous inflammation to be dreaded after this operation. In fact the nervous system is rarely if ever affected, and the operation scarcely ever proves fatal from nervous excitability. As to the occurrence of hæmorrhage, in spite of what has been written, and what may still be persisted in by some, it is not in general a formidable complication; and its fatal effects are rarely to be met with, though occasionally, from small and frequent repetitions, great debility and even death is produced.

British Hospital Reports.

ST. THOMAS'S HOSPITAL.

Efficacy of Iodine on Secondary Syphilis.

This affection, which, up to the present day, has excited so much medical speculation, and in the cure of which so many different opinions have been advanced, appears at last, by numerous experiments that have been made in the above hospital, and of which the following cases will be a proof, capable, at least in some of its stages, of being perfectly eradicated. The forms of the disease have been so fre-

quently alluded to by men of the first talent, its progress so accurately examined, and its effects so frequently observed, that it will be needless for us here to enter into a lengthy description. The period, however, at which secondary syphilis makes its appearance after the primary symptoms, has been, especially by the army surgeons of this country, limited to a certain period, the fallacy of which must have been observed by every practical surgeon or physician. Facts are every day to be witnessed in these hospitals, in which periods of a greater or less extent have elapsed since the incubation of this virus into the circulating system—weeks, months, and even years—as will be seen by the following observations.

The parts affected by this poison, after the virulence of its first absorption, are so generally the same, and so frequently observed, that the subjoined cases will be sufficient to illustrate the different surfaces attacked. Whether or not it is owing to the modification of the virus by the changes it is liable to undergo from the alteration of the system by treatment, or from the peculiar idiosyncrasy of the constitution attacked, upon its ultimate characters, at present remains in great obscurity. However, it is a well-known fact, that if the disease be left to a spontaneous cure in its primary stage, its secondary effects are much more virulent, and the cure of the former much protracted; at once showing the importance of subduing, as early as possible, the effects of the virus.

We will here enter into a short description of the secondary or constitutional symptoms, to which the proper local signs of syphilis are sure to lead, if not checked in their progress; as the cases will merely illustrate the state of disease at the time under treatment. The symptoms are (but of course liable to vary) soreness and ulceration of the tonsils, and neighbouring parts of the pharynx; the ulcers are of a distinctive character, foul, and rugged, excavated in the centre with a whitish-brown slough, and surrounded by an elevated, red, erythematous outline. The conjunctiva of the eye is generally the next to suffer, becomes inflamed, and ulcerations may be observed on the eyelids and angles of the eye. An eruption appears on the skin, which desquamates in scurf, afterwards in scales, and at a still more advanced period in scabs, leaving a foul ulcer, which by degrees becomes more excavated, and discharges a fluid of an offensive nature.

At a more advanced period, irregular pains shoot about the limbs, which from heat, become aggravated. The periosteum and bones at length become affected, nodes supervene, which are followed by caries of the bone; it thus continues to spread, till it destroys the patient.

It is more particularly this latter stage of the disease that has baffled all attempts of treatment to overcome it, and to the ravages of

which so many human beings have fallen victims.

CASE I.—Ellen de Ling, aged 30, was admitted into Anne's ward of this hospital, with severe pains in her legs, from which she had suffered for three months; so severe were they when admitted, that she could scarcely walk; her constitution, which had been generally good, was much impaired; countenance sallow; complained of great debility, and was emaciated. Dr. Williams, under whose care she was admitted, prescribed eight grains of the hydriodate of potass out of camphor mixture, to be given three times a-day. After taking this medicine for three days, the pains became much alleviated; the periosteum, which covered the inner surfaces of the tibiae, and were rugged, became less painful and smoother; in the course of a fortnight all the symptoms had disappeared, her countenance became more blooming, and from her own statement, which also was evident to all who visited her, she got fat while under the influence of the medicine, and on the 19th of June, three weeks from the time of her admission, she was discharged perfectly cured.

CASE II.—Jane Parish, a mantua-maker, aged 22, of scrofulous diathesis, came in the same ward, under Dr. Williams, with ulceration of the pharynx and rupia, the scabs on the nose and several parts of the body had formed into deep ulcers, the most severe situated especially on the right arm, the size of which were as large as a crown piece. She also suffered from severe pains in her limbs, which deprived her from all rest; countenance pallid; bowels regular. States that three months previously she had the venereal disease, for which her mouth was made very sore, and the chancres readily healed. Great debility of constitution when admitted. Dr. Williams prescribed in this case, as the disease appeared particularly to attack the mucous, and cutaneous surfaces, decoction of sarsaparilla with wine and sago; and ordered the ung. hydr. nit. to be applied to the ulcers. She has now been in the hospital under this treatment about three week, all the sores have kindly healed, her general health has become much improved. All pains have left her, and she is now in nearly a fit state to be discharged from the hospital.

CASE III.—Louisa Wilmott, a married woman, aged 34, who states that six years ago, when first married, her husband gave her the disease, which, after submitting to a mercurial course, subsided; and not until five months ago she experienced any secondary symptoms. About that period she received a blow from her husband on the nose, pain supervened, fistula lachrymalis ensued, for which she was then admitted into the hospital under Mr. Green, who relieved her by performing the operation. After this her nose continued

to trouble her; felt heat and pain about the internal parts of it; and at different times small pieces of bone were discharged from the nostrils. She also suffered from severe pains in her limbs, increased when in bed; these were soon succeeded by hard lumps or nodes forming on the inner surfaces of the tibiae, which became so tender that the least pressure caused excessive pain. On the 29th of May she came into Ann's Ward, under Dr. Williams's observation; the symptoms then continued as above, and Dr. W. prescribed the hydriodate of potass in camphor mixture. This she has continued to take up to the present time; in the course of a week after its use the pains subsided, and the osseous deposition has been gradually disappearing. Since she has been taking the medicine her nose has felt much easier, and no bone has within this time been discharged.

(To be continued.)

GUY'S HOSPITAL.

Hernia.

A. B., a labouring man, *setat.* 40, came into the hospital on June 18th. He had been afflicted with femoral hernia during the last four years; the intestine slipped down several times, but he had always been able to return it without difficulty. On the day of his admission, after eating a hearty dinner, the hernia suddenly came down, and resisted all his endeavours at reduction. When he was brought into the hospital he was placed in a warm-bath, and the taxis resorted to with success. An enema was then given. A few hours after the operation the patient complained very much of pain in the abdomen, and several urgent symptoms set in. He was ordered to be bled to sixteen ounces, and to take calomel and opium. These symptoms excited some surprise, as there was no unnecessary force used in returning the intestine; the patient was bled a second time, and purgatives administered. These measures succeeded in affording relief, and the patient is now going on very favourably. Mr. B. Cooper, in his observations on this case, took occasion to caution the pupils against making use of too much violence in returning a hernia; such bad treatment was succeeded by symptoms as took place on this occasion. He was, however, convinced that no unnecessary force was resorted to in this instance.

Lithotomy.

On Tuesday a very fine child, about five years of age, was brought into the operating theatre, in order to undergo the operation for stone in the bladder, which he has been labouring under for a long time. Mr. Aston Key performed the operation in the usual manner, and extracted a stone about the size of a large pea. The operation was performed in about ten seconds.

Extraction of a Ball from the Arm.

A very robust and well-looking young man was next brought in. He had been serving in Don Pedro's army, during the late Portuguese war, when he received a ball in the arm, which had not been extracted. On reaching London he came to this hospital in order to be relieved; several small shot were also lodged in his arm, and his person when stripped presented various wounds, proving that he had not fought with impunity. Mr. Key made two incisions in the arm, a few inches below the head of the humerus, and after a short search felt the ball, which he extracted with a forceps. The hæmorrhage was trifling and no arteries were tied; the ball was as large as a walnut.

CORRESPONDENTS.

Mr. Tatham's paper will appear at our earliest convenience.

Mr. Langley's communication is under consideration.

M. Moscati. — It is not characteristic of Englishmen to refuse "redress or justice to a fallen and persecuted foreigner in this land of civilisation and liberty;" nor is it our practice to attack either native or foreigner in this journal, without giving an opportunity of a moderate reply. But if we receive a reply totally foreign from our remarks, and one that is intemperate and grossly offensive to a third party, which we have already refused to insert, and which our contemporaries had previously refused to publish, we do not consider the writer entitled to complain of want of redress or justice at our hands. When controversialists descend to designate each other "liars," we consider their effusions unworthy of a place in our pages. But had we the bad taste to insert one communication, we should most certainly have admitted the other. We refused to notice either, nor shall we be induced to alter our determination.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE XCVII., DELIVERED APRIL 29, 1833.

GENTLEMEN,—I will now describe to you the manner of operating upon the external or oblique inguinal hernia. The hair having been removed from the parts which will be in the track of the knife, and the bladder emptied, the first incision should commence an inch above the external angle of the abdominal ring, and it should extend obliquely downwards, and inwards over the middle of the tumour to its lower part, except when the hernia is very large. This incision divides the skin, cellular substance, and the external pudic artery, as it crosses the sac near the abdominal ring. It is generally admitted, gentlemen, that, by directing the incision obliquely downwards and inwards, you lessen the chance of injuring the spermatic vessels, should they happen to be situated towards the front of the sac. From the remarks on the surgical anatomy of bubonocoele, already delivered, you will be apprised, that the division of the integuments brings into view the fascia superficialis. This is to be laid open, by which you will expose the fascia of the cord, or fascia spermatica, as it is termed, derived from the intercolumnar fascia, at the abdominal ring, and generally forming one of the thickest coverings of the hernia. In order to accomplish this purpose, you should first make a small opening through the exposed fascia, which may be safely done by taking hold of a small portion of it with a pair of forceps, and then dividing it cautiously close to the point of the forceps with the edge of the knife turned horizontally.

Then having made an opening, you may introduce a probe, or a director, and with a common scalpel, or a curved bistoury, divide

the fascia upwards and downwards as far as the external incision reaches.

Thus you will bring into view the next covering of the hernial sac, namely, the expansion formed by the cremaster, which must be opened and divided in the same manner as the fascia. Having done this, you come to the funnel-shaped process, or the continuation of the fascia transversalis between the upper portion of the cremaster and the hernial sac, but which is so slight and so soon lost in the cellular tissue between the sac and the cremaster, that it is not recognised by some of the best writers on hernia.

Now the cellular substance on the outside of the sac will be brought into view, and, after having carefully divided it, you come to the hernial sac itself; a little piece of the anterior and lower portion of which is to be lifted up between the thumb and fore-finger, and carefully examined, to learn whether the fold thus raised includes any portion of bowel. If it does not, you then take hold of it with a pair of forceps, and cautiously open it, with the edge of the knife directed horizontally. Surgeons choose to open the hernial sac at its anterior and lower part, because if there be any fluid in it, it will gravitate to this part, and be a kind of protection to the intestine from the edge of the knife.

Sometimes, gentlemen, much perplexity is evinced in distinguishing the sac itself from the intestine. However, the circular arrangement of the vessels of a piece of intestine, and its smooth polished surface, sufficiently characterise it from the hernial sac, which has a rough cellular surface and is closely connected to the surrounding parts.

Having made an opening into the hernial sac, you are to introduce a director, and with a probe-pointed bistoury lay it open to the extent of the other incisions. The next thing, gentlemen, is to divide the stricture.

Now the stricture may be situated either at the abdominal ring, and be formed by the margins of this opening, or else, what is more frequent, within the inguinal canal, where it is produced by the lower edge of the internal oblique and transverse muscles, or lastly, at

the internal ring itself, about an inch and a half from the external ring, in the direction towards the anterior superior spinous process of the ilium.

If the case require it, you may now introduce a director into the neck of the sac, within the abdominal ring, and with a probe-pointed bistoury, cut the stricture *upwards and outwards*, or, if you please, *directly upwards*, the recommendation of which last plan, suggested as a general one by Sir Astley Cooper, is, that you will not endanger the epigastric artery by it, whether the case be an external or an internal bubonocoele. Were you completely sure, however, that the case were an *internal* bubonocoele, you might safely divide the stricture upwards and inwards, the epigastric artery lying on the outer side of the neck of the sac, the very reverse of what happens in the external or most common form of bubonocoele.

When the stricture is at the upper opening of the inguinal canal, the abdominal ring itself should not be cut, unless it prevent the operator from reaching the more deeply seated strangulation.

The next business, gentlemen, is to return the protruded parts, if sound, and free from adhesions; and this will be considerably facilitated by bending the thigh. Sometimes, it is true, you will have a good deal of difficulty in separating adhesions, which may even be such as to prevent the reduction of the protruded parts altogether; but this is unusual. In such a dilemma, by dividing the stricture, you render as much service as surgery can accomplish; and the patient will not always be lost, though you may be obliged to leave some of the bowels protruding. The intestine, if possible, should always be reduced, unless it be found in a state of actual mortification. The appearance of dark brown chocolate discolourations are no objection, and they should be discriminated from the *black* or *purple spots*, which indicate mortification.

With respect to *adhesions*, the intestines are not often firmly adherent to one another. In general, the strongest adhesions are those between the omentum and the inside of the sac. Slight adhesions of the intestine to the inside of the sac may be gently broken with the fingers. If such connexion should require the use of the knife, the safest plan is not to cut too near the bowel, but to remove the adherent parts of the sac, and return them with the intestine into the abdomen. But, gentlemen, if the adhesions should be within the neck of the sac, the inguinal canal should be more freely laid open, so as to bring them into view.

One important rule, after the reduction, is gently to introduce the finger, and be sure that the parts are all fairly and freely returned, and not suffering any degree of constriction, either by the margin of the internal oblique and transverse muscles, or the inner opening of the inguinal canal, or other causes,

and to be confined by any adhesive bands formed across the mouth of the hernial sac, as displayed in the preparation which I now hand to you for your inspection.

Treatment of Omentum—In entero-epiplocele, the omentum, if healthy, is to be reduced after the intestine. If much enlarged, and indurated, or gangrenous, diseased, or mortified, the unsound portion is to be cut off, and the arteries taken up with a tenaculum, and secured with fine thread or silk. Then what remains is to be reduced, with the threads left in the external wound.

Treatment of Mortified Intestine.—In most cases, gentlemen, when the intestine mortifies in a hernial sac, the latter part, its coverings, and the integuments, also become gangrenous. If the patient continue to live, the intestine bursts, and the *faeces* at length find an outlet, either through the wound made by the surgeon, or an opening formed by the separation of the sloughs. Of course, before the bowel mortifies, the neighbouring inflamed part of it becomes adherent to the neck of the sac. After this the final result may be of three kinds: either the death of the patient; his recovery, with the loathsome annoyance of an artificial anus; or the gradual diversion of the *faeces* from the wound to their natural course again, the cicatrisation of the part, and a complete cure.

The principal thing, on which the re-establishment of the continuous state of the intestinal canal depends, is the adhesion which the living portion of bowel, adjoining the mortified part, contracts with the peritoneum all round. In this manner, the escape of the contents of the bowel into the cavity of the abdomen is in general completely prevented. The two ends of the sound portion, after the sloughs have been thrown off, become connected together through the medium of a membranous cavity, which previously constituted a portion of the peritoneal sac. The gradual contraction of the wound closes the membranous cavity externally, and thus the continuity of the canal is restored. The two ends, however, are not joined, so as to form an uninterrupted cylindrical tube, like that of the natural gut; but they are united at an angle more or less acute; and the matter, which goes from one to the other, describes a half circle in the membranous cavity, while the two ends of the bowel always lie in a more or less parallel manner by the side of each other; the upper with its orifice directed towards the external wound by the *faeces*, as long as they take that direction, while the lower is less capacious.

This account will enable you to understand, that there must be a considerable projection, or jutting angle, between the orifices of the bowel, directly opposite the communication between the cavity of the intestine and that of the *semi-circular funnel-shaped membrane*, as I think, it is termed by Professor Scarpa. Now, it is this projecting ridge, or angle, that

forms a material obstacle to the direct passage of the *feces* from the upper into the lower portion of the intestinal tube. It constitutes one of the chief hinderances to the cure of an *artificial anus*; and it is by destroying it by the pressure of a pair of forceps constructed for the purpose, that Baron Dupuytren, and other surgeons, have often succeeded in curing that loathsome affliction.

Here, I may also observe to you, gentlemen, that much of the danger of an *artificial anus* will depend upon its degree of nearness to the stomach. Thus, if the opening be in the jejunum, there will be so small an extent of surface for the absorption of chyle, that the patient will die of inanition.

If you first detect mortification of the bowel on opening the sac, and there should be only one or two spots, you are to divide the stricture; and if the gut be not adherent, it is to be reduced.

When the chief part or the whole diameter of the bowel is mortified, the indication is to make an outlet for the intestinal matter, by a free incision through the sloughs, and by cutting the stricture if it should still exist. Here, of course, all idea of reduction of the parts is out of the question.

Gentlemen, in operating upon very large hernia of long standing, I wish you to remember, that the proper plan is to divide the stricture, without laying open the hernial sac, or attempting to reduce the parts. The free exposure of the cavity of a bulky hernia is itself a frequent source of fatal mischief.

In operating upon hernia within the inguinal canal, but not protruding through the ring, you should make the incisions in the direction of the spermatic cord. In such a case, the stricture will be found at the internal ring.

With respect to the treatment after the operation, I may observe, that the wound is to be closed with a suture or two, and lightly dressed. Evacuations from the bowels are to be promoted by means of small doses of sulphate of magnesia, dissolved in peppermint water, and aided by clysters, if requisite. The patient must not, however, be allowed to sit upon the night-stool, as doing so would be likely to bring on a protrusion of the bowels again. It is safer to put a bed-pan under him. If tenderness and tension of the belly, with costiveness and febrile symptoms, should come on again, in the course of a day or two, you should have recourse to local and general bleeding, poppy head fomentations, and the exhibition of castor oil. If the stomach should be much disturbed after the operation, the sulphate of magnesia may be given in the effervescing saline draught, with or without a few minims of the tincture of opium, or hyoscyamus.

Before the patient leaves his bed, a truss is to be applied.

When the bowel has been much discoloured, it will sometimes give way two or three days after the patient has appeared to be going on

well; and the patient is destroyed by peritonitis resulting from effusion of the contents of the bowels into the cavity of the peritoneum.

In the Operation for the relief of a Strangulated Direct Inguinal Hernia, remember, gentlemen, that the coverings of the sac are the skin and superficial fascia, the spermatic fascia, the tendinous fibres of the internal oblique and transverse muscles, if not torn, or burst, and the fascia transversalis. It is only in the vicinity of the abdominal ring, that this hernia has any fibres of the cremaster spread over it. The several investments here specified are to be divided, much in the same way as those of the external bubonocoele, and the stricture cut, either upwards and inwards, or directly upwards, as preferred by Sir Astley Cooper, for a reason already explained to you.

The Femoral or Crural Hernia is so called, when the hernial sac and its contents protrude under Poupart's ligament at the inner side of the femoral vein, so as to be situated in the bend of the groin, upon the pectinalis muscle, between the gracilis and sartorius. The protrusion takes place, in fact, through the crural or femoral ring, or the opening destined for the passage of the femoral absorbent vessels. When once the sac has descended beyond this opening, the hernia has more room to extend itself forwards, and to each side, and the integuments now become raised into an oval swelling, the greatest diameter of which is nearly transverse.

The femoral hernia is frequent in women, who have had children; but is rare in young girls. In men, a hernia more readily forms through the inguinal canal, by following the course of the spermatic vessels, than under Poupart's ligament; but the latter case is far from being so uncommon in them as sometimes represented.

The tumour produced by a femoral hernia, is apt to be mistaken for an enlarged gland. A gland can only become enlarged by the gradual effects of inflammation; the swelling of a femoral hernia comes on suddenly; and, when strangulated, occasions the train of symptoms which I have already described, which symptoms an enlarged gland could never occasion.

When the expanded part of a femoral hernia lies over Poupart's ligament, it may be mistaken for a bubonocoele; but, gentlemen, you may always make out the true nature of the case by observing, that the neck of a femoral hernia has Poupart's ligament above it. In the bubonocoele, the spine of the pubes is below and behind the neck of the sac; but, in the femoral hernia, it is on the same horizontal level, and a little on the inside of it.

When a femoral hernia expands in the bend of the thigh, its shape is oval, and its greatest diameter is placed transversely; but, whatever may be the size of a common inguinal hernia, it has an oblong pyramidal shape, with its fundus not inclined towards the

ilium, but in the direction of the spermatic cord towards the scrotum.

Besides the symptoms common to all hernial swellings, the femoral hernia, when of a certain size, has some which are peculiar to it, as stupor, and sense of weight in the thigh, and sometimes œdema of the leg and foot; circumstances accounted for by the pressure of the hernia on the blood vessels, lymphatics, and nerves, which pass out of the pelvis in its vicinity.

Now, gentlemen, with respect to the *surgical anatomy of femoral hernia*, I will take this opportunity of reminding you of a few circumstances, which, no doubt, you have already had a masterly description of, from my distinguished friends, the professor and demonstrator of anatomy at this school.

The *crural arch* is a term applied to the lower margin of Poupart's ligament, the space intervening between which and the ilium and os pubis, is in a great measure closed on the side towards the abdominal cavity by the union of the *iliac* and *transverse fasciæ* at Poupart's ligament, which fasciæ, in fact, shut up all that space, which is between the anterior superior spinous process of the ilium and the femoral vessels. Hence, gentlemen, it is manifest, no hernial protrusion can ever happen in the space below the crural arch to the outside of the femoral artery and vein. The occurrence is prevented not only by the junction of the iliac and transverse fasciæ within, but also by the *fascia lata* without, which, in this situation, is strong and closely attached to the subjacent parts. Now the femoral hernia takes place through the *crural ring*, which is situated under the crural arch, more towards the pubes, in fact, between the thin posterior border of the *crural arch*, termed *Gimbernat's ligament*, and the femoral vein.

As the protrusion does not take place through a simple aperture, but follows a course of some length, the expression *crural canal*, employed by Scarpa and Cloquet, is perhaps more correct than that of *crural ring*. It is at all events the superior or posterior aperture of the *crural canal* which you are to understand as being implied by the *crural ring*, the canal itself extending obliquely downwards and forwards for a half or three-quarters of an inch, and terminating below at the oval depression, for the vena saphena major.

The viscera descend at first nearly in a perpendicular direction, and come into the hollow in front of the pectinalis, but the hernia then turns forwards, and directs itself rather towards the ilium, the fundus of the sac being sometimes actually tilted up, as the expression is, over the crural arch.

Then, gentlemen, it is worth your while to remember, that as the protrusion descends over the pectineal line, or close attachment of the pectinalis muscle to the pubes, it must be situated over the pubic portion of the fascia lata. *Gimbernat's ligament*, which is a part of so much importance in the anatomy of

femoral hernia, I think, will be best understood by considering it, as a prolongation or extension of Poupart's ligament, which, when it approaches the os pubis, becomes suddenly broader, and is attached by this broad portion along the whole length of the angle and crista of that bone.

The posterior edge of Gimbernat's ligament is concave, thin, and sharp, and the ligament itself about three quarters of an inch in breadth.

Now the *crural ring*, through which the femoral vessels descend, is formed by this posterior edge, or, as it is sometimes termed, the base, of Gimbernat's ligament, directed towards the crural vein—externally by the femoral vein—or rather by a production of fascia, or a kind of septum placed between that vessel and the great lymphatics of the thigh; anteriorly by the under edge of the crural arch, or by Poupart's ligament; and posteriorly by the os pubis.

But into the crural ring productions both of the fascia transversalis and fascia iliaca always descend, so as to form at once a *tubular sheath for the femoral vessels*, and a lining for the crural canal, the front half being formed by the fascia transversalis—the back by the fascia iliaca; and, as Sir Astley Cooper has clearly explained, it is through the inner side of the sheath next to the pubes that the femoral absorbent vessels pass into the abdomen, the opening for which gives a cribriform appearance to this portion of the tubular sheath. The crural canal is wider above than below: its external side, which is straight, being closely applied to the femoral artery, while its inner margin extends downwards and outwards from Gimbernat's ligament to the femoral vein, just on the inner side of which vessel is an oval aperture merely occupied by a lymphatic gland, and some absorbents and cellular substance, through which opening the hernia, in the continuation of its descent, passes towards the point of the fascia lata, at which the vena saphena major gets to the femoral vein, which point is included within what is called the *falciform process*.

The very lucid and original explanations of the anatomy of femoral hernia by Sir Astley Cooper reflect the highest honour on himself, on his profession, and, I would also say, on his country. We knew little about various points in the minute anatomy of femoral hernia until he demonstrated them, and published a clear description of them in the great work which is upon the table. If you turn to this source of information, or, what is better, if you dissect and open the tubular sheath, you will find that it contains two membranous partitions, one passing between the artery and vein, and another between the vein and the absorbents. The artery and vein completely fill up the spaces in the sheath allotted to them; but the absorbents being but loosely connected by cellular tissue, do not always afford sufficient resistance to prevent the descent of the viscera

in this situation, and the formation of a crural hernia. It is this opening, then, in the inner part of the sheath which is really the aperture by which the bowels descend, and which is situated, as already stated, between the thin crescentic edge of the base of Gimbernat's ligament and the femoral vein, or rather the septum. Or, I may say, that the hernia protrudes through the division of the tubular sheath designed for the transmission of the principal trunks of the absorbents from the lower extremity, scrotum, and superficial parts of the hypogastric region into the pelvis.

The *falciform process* is easily comprehended, when you remember that the fascia lata has two origins, one from the lower border of Poupart's ligament, all the way from the anterior superior spinous process of the ilium, to the tuberosity of the os pubis. This, which is the thickest and strongest, is called the *iliac portion*, and it covers the sartorius and rectus muscles, the femoral artery and vein, and the anterior crural nerve, its breadth in the adult subject being from four to five inches.

Then, gentlemen, with regard to the *inner or pubic portion* of the fascia lata, it arises from the pubes, in front of the origin of the pectinalis muscle, which muscle it covers, together with the adductor muscle, and afterwards unites with the iliac portion of the fascia lata, under the great saphena vein. Of course, it lies behind or under the femoral vessels, while the iliac portion is in front of them; and you know, that above it is continuous with the iliac fascia. From this description, gentlemen, it is manifest, that where the pubic portion of the fascia lata joins the iliac portion under the vena saphena major, there must be an aperture left for the passage of that vessel. This opening is termed the *saphenous opening*, the concave external margin of which consists of part of the *falciform process*, first correctly described by Mr. Allan Burns.

Scarpa represents the iliac portion of the fascia lata as connected with Gimbernat's ligament; and Mr. Lawrence describes the upper end of the falciform process, not merely as passing in front of the femoral vessels just as they emerge from behind the crural arch, but as bending under Poupart's ligament, so as to unite with the thin border of the arch called Gimbernat's ligament.

The great saphena vein passes over the inferior sharp edge or lower horn of the falciform process, and there joins the femoral vein. Then, between the parts just described and the skin you have the *fascia superficialis*, quite distinct from the fascia lata, and consisting of two layers, between which lie some adipose matter and the superficial inguinal glands.

In femoral hernia the viscera descend through the crural ring, pushing before them the peritoneum. They then pass into the tubular sheath of the femoral vessels, and afterwards turn forwards, and even upwards,

through the saphenous opening in the fascia lata, so as to lie over the iliac portion of the fascia lata.

The coverings of the femoral hernia, gentlemen, are the *integuments*, the *fascia superficialis*, and the *fascia propria*, or tubular sheath of the femoral vessels, besides the peritoneal hernial sac. The epigastric artery passes obliquely upwards and inwards about half an inch from the external side of the neck of the sac. When the obturator artery arises from the epigastric, it may go either near the outer or inner side of the neck of the sac to the obturator foramen. When the common trunk of these vessels, so originating, is long, and the place where the obturator goes off from it is high up, the latter vessel may descend near the upper and inner border of the crural ring. But, when it arises from the epigastric lower down, it will then pursue its course downwards near the external margin of the neck of the sac. The spermatic cord, or, in women, the round ligament, passes directly over the superior part of the hernia. All these are essential things to be considered in operating on a femoral hernia; a subject, with which I shall begin the next lecture.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XXVII.

Analysis of Symptoms of Cerebritis—Inconstancy of Pain—Intermittent Pain—Phenomena of the Eye—State of the Pupils—Researches of Parent and Martinet—Relief by Convulsions—Dangerous Effects of Opium—Delirium—Phenomena of Organic Life—Sympathies of the Digestive and Respiratory Systems—Treatment of Hydrocephalus—Mercurial Gangrene of the Mouth—Mode of Treatment.

GENTLEMEN,—Before we leave the subject of inflammation of the brain, I shall draw your attention to a brief analysis of some of the more prominent symptoms of this disease; and here I am anxious to impress upon you, that the true mode of studying this subject is not by reading the descriptions given by this or that systematic writer, but by the careful perusal of *monographs*, in which the details of a great number of cases, occurring under different circumstances, are accurately reported. You would be mistaken, indeed, if you were to conclude that you had acquired a thorough knowledge of the symptoms of phrenitis or arachnitis by reading the description of Cullen, Thomas, or Mason Good. The only mode of studying the subject properly is, to take accurate notes of every case which you meet with,

and to study with care those monographs in which a number of cases, attended by different symptoms, are detailed with impartiality.

I would not occupy your attention further with this subject, but that there is much error prevailing with respect to inflammation of the brain and its membranes. Persons are in the habit of supposing that these symptoms are always constant and well marked, but, the truth is, they are subject to very great varieties. The first symptom to which I shall call your attention is *pain*. This, you will recollect, is a prominent symptom of most visceral inflammations where the disease is situated on, or close to, the surface of the organ, but when it is deep-seated this symptom becomes more or less obscure. Now, in a case of arachnitis, we have a double source of pain, one depending upon the affections of the serous membrane, the other arising from the circumstance of disease being situated on the surface; and hence it is, that, in the great majority of cases of arachnitis, pain is a constant and prominent symptom. Still, if you were to conclude that pain is *always* present in arachnitis, you would be wrong, for there are many cases on record in which it was either partially observed or completely absent. You will be greatly assisted in your pathological studies by attending to the different results of inflammation of analogous structures, for we find that in some of the inflammatory affections of serous membranes there is little or no pain. We may, for instance, have pleuritis, pericarditis, and even peritoneal inflammation latent, so far as pain is concerned; nay, many persons have gone so far as to say, that it is only where the muscular tissues of the belly are engaged that we have pain in peritonitis. I have seen pericarditis run through all its stages without any pain being complained of by the patient. Now, if this absence of pain be a matter of no unusual occurrence in some inflammatory affections of the pleura, pericardium, and peritoneum, there is no reason why it may not occur in some cases of arachnitis. Still, it must be acknowledged, that pain is one of the most remarkable and constant symptoms of arachnitis, and that, of all the serous membranes, the arachnoid seems to be endowed with the greatest sensibility.

We might inquire here, whether the pain of cerebral inflammation be significant of any particular lesion of the brain. I believe that upon this point the state of our knowledge is very unsatisfactory. Pain, as a symptom of cerebral inflammation, occurs in very different cases. We may have it in connection with disease of the superior, lateral, or inferior parts of the brain; we may have it in cases where the result of the disease is a serous, hæmorrhagic, or purulent effusion. The rule, then, to be borne in mind is this:—first, that it is present in the great majority of cases of arachnitis; next, that it may accompany many different lesions; thirdly, that it may be absent; and lastly, that with the same lesions we may

have pain in one case, and absence of it in the other.

The next subject for inquiry is, does the seat of pain generally point out the seat of inflammation? Andral distinctly affirms that it does not. In some cases, pain of the frontal region has been found to accompany disease of the ventricles, and pain in *one side* of the head, an affection of the arachnoid covering of both hemispheres. We see the same thing occurring in the case of other serous membranes. Thus, in the pleuritic inflammation of phthisis, pain is very seldom felt in the situation of the disease, but generally lower down, and I have seen some cases in which pain has been complained of only in the sound side. I recollect a case of very extensive pneumonia, in which the patient complained only of some pain in the region of the kidney and small of the back.

The pain which accompanies arachnitis generally sets in at an early period of the disease, and is characterised by great intensity, two circumstances in which it resembles the pain of pleuritis. In most cases, it is found that any thing that impedes or oppresses the circulation of the brain, increases this pain, and hence it is that some practitioners are led to think, that if pain of the head be relieved by pressure, it cannot be inflammatory. Now, I wish to call your attention to this point, because, in some cases where evident marks of arachnitis were found after death, it was observed that during life the pain of the head was relieved by pressure. The patients have been found with a bandage tied firmly round the head, from which they experienced decided relief, and yet a post mortem examination gave unequivocal proof of the existence of arachnitis. So far, then, as these cases go, it appears that the mere fact of pain being relieved by pressure does not prove that it is unconnected with an inflammatory cause. The pain, too, of an arachnitis may be intermittent, and continue to exhibit this character even for a considerable length of time. I have seen many instances of this in children, where the little patient was seized with acute pain of the head at a particular time of the day, which, after a few hours' duration, subsided, and then returned again the next day at precisely the same hour, and continued in this way for several weeks, until at length his friends were surprised by the unexpected supervention of coma, convulsions, or blindness. I knew two cases of this kind in which the intermittent character of the pain was so prominent as to engross the practitioner's whole attention, so that the real nature of the affection was overlooked, and bark prescribed. I have now witnessed three or four of these regular quotidian attacks of pain in children, which after continuing for days and even weeks were suddenly followed by perfect blindness, in some cases with, and in others without coma.

You might here ask, whether pain is to be considered as a diagnostic of arachnitis?—I cannot say it is. We constantly meet with severe pain of the head without arachnitis, and every one knows that the headach of fever is by no means an indication of inflammation of the brain. In many cases of hysteria, the headach and determination of blood to the head are violent, and yet unconnected with inflammatory action. I know a young lady who is frequently attacked with most agonising headach, accompanied by violent throbbing of the carotids and great heat of the face and scalp. Yet in this case it is plain that the pain cannot be inflammatory, for she has been subject to these attacks once or twice a week for the last six years, and yet continues otherwise in a state of good health. If her disease were to be measured by the violence of the pain and determination of blood to the head, it would be natural to expect that death would have long ago put a period to her sufferings. This is another proof of the truth of the opinion, that there is no single pathognomic symptom of disease. Bear this in mind. I might go farther, and say, that whether we looked to symptoms or to signs the rule was the same. The man who merely looks to a single sign or symptom will frequently err; it is only from the whole group of signs and symptoms presented by a disease that we can arrive at any accurate diagnosis.

The state of the eye, in cases of arachnitis particularly, has attracted much attention. On this subject much valuable information has been obtained by the laborious investigations of Andral, of which I shall give an abstract. He states that the phenomena of the eye, in cases of cerebral inflammation, may be reduced to three classes; its motions, the various conditions of the pupil, and the state of vision. With respect to the first of these, it may be observed that in some cases we find the eyeball in constant motion, in others it is quite fixed, while in others the balance of muscular power is lost, and there is a constant tendency to strabismus of one eye or both. Of all these varieties in the state of motion, the last appears to be the most valuable so far as the diagnosis of arachnitis is concerned. By many persons this strabismus is looked upon as a sign that *effusion* has taken place, and that the disease has reached its incurable stage; a position which I am inclined to doubt, from having seen cases recover in which this symptom was present. However, Andral looks upon strabismus as a very valuable sign, and thinks that of all the lesions of motion of the eye it is the most important with respect to the diagnosis of *arachnitis of the ventricles*. With respect to the condition of the pupil, it is stated in books that in the early stage you have a contracted, and in the advanced a dilated pupil, and that the latter condition signifies that effusion into the brain has taken

place. Now the truth is, that this statement must be received with great caution, and as admitting of numerous exceptions, for it has been established that the same lesions of the brain are sometimes accompanied by very different conditions of the pupil, and *vice versa*. Parent and Martinet, who have investigated the subject carefully, are the best authorities on this point, and I shall give a brief abstract of their experience. In cases where *both pupils were dilated*, they observed that in some there was effusion into one of the ventricles, in others into both. In cases where there was no dilatation they observed that in some there was serous or purulent effusion under the arachnoid, while in others, in which there was no effusion whatever, the pupil was dilated. Lastly, it was found that in some cases, where only one pupil was dilated, there was effusions *into both sides of the brain*. You might here ask, whether effusion into the substance or on the surface of one side of the brain is connected with a dilated condition of pupil? In reply to this, it may be stated, that effusion into the substance not of one but of both hemispheres has been known to be accompanied by a contracted state of the pupil to the last. You may also have one pupil contracted and the other dilated; nay, you may have an *alteration of these conditions*, the right being dilated to-day, the left to-morrow. The mere circumstance, then, of dilatation or contraction of the pupil is no sign, when taken by itself, as to the seat or even the existence of effusion, for you may have either condition with or without effusion, and you may have dilatation of the pupil of one eye with an effusion into both sides of the brain. As a general rule, however, it seems to be made out, that in most cases of cerebral inflammation terminating in effusion, there is often, towards the advanced period of the disease, some dilatation of pupil, and that this condition generally marks the occurrence of effusion.

With respect to the affections of the function of vision, there are great varieties. Some patients have double vision; others see sparks of fire, or *muscæ volitantes*. There are many other phenomena of the kind, causing a great variety in the symptoms, and this variety is found to depend more on the susceptibility of the brain to irritation, rather than on the mere existence of irritation of the serous membrane investing it. The same rule applies to all cases of serous inflammation, the phenomena of inflammation varying according to the susceptibility of the organ which the inflamed membrane covers. Thus, for instance, one patient will have pericarditis with palpitations of the heart, another without them; their occurrence or non-occurrence merely showing that the heart is more or less susceptible to irritation. So it is with respect to the brain, and the symptoms of deranged vision are connected with the greater or less susceptibility of the organ, which we know varies very con-

siderably in different persons. This remark applies to all the forms, and, I believe, all the phenomena of meningitis.

In acute disease of the brain and its membranes, we often have convulsions and paralysis, and in these symptoms also we find great variations. In some we have convulsions of one side, in some of both, in others we have paralysis, but scarcely any convulsions. The same remark also applies to these symptoms as to some already mentioned, namely that we cannot from them alone form an accurate estimate of the situation or amount of disease. You may have convulsions and paralysis of various kinds with the same kind of lesion, and you may have a variety of lesions with the same paralysis and convulsions. The only thing that appears to be pretty well established is this, that generally speaking, in cases where the right side of the brain is engaged, you have convulsions and paralysis of the left side of the body, and *vice versa*.

Before I proceed to speak of delirium, I think it necessary to say a few words more with respect to convulsions, as I find Andral has not touched on a point to which I beg to call your attention. The occurrence of convulsions in a child, labouring under symptoms of inflammation of the brain, is always looked upon as formidable, and indeed it is natural that convulsions, to persons unacquainted with pathology, should seem to point out a great intensity of disease. I have, however, been long of opinion that convulsions occurring during the existence of hydrocephalus in children, or of meningitis in adults, are not so dangerous as persons generally think. I will even go so far as to say, that the worst cases I have seen, in which a cure was effected, were those in which there were the greatest and most violent convulsions; and that in most of the cases which appeared to go on without any benefit from medicine, there were scarcely any. I am of opinion that convulsions are often of benefit by giving relief to the brain. This statement must appear somewhat paradoxical, but I trust I shall be able to prove to you that it has some foundation in truth. Broussais has taught that there appear to be two great modes of reaction in the economy, to obviate the effects of anormal stimulation applied to important viscera, fever and convulsions. The irritations which attack the cerebro-spinal system may be relieved by convulsions; those which attack the viscera may be relieved by fever and secretion. This doctrine, I think, might be expressed otherwise. The irritations of organs are often relieved by an increase, with or without alteration, of *their secretions*. But as we have used the term *secretion* to express something material we apply the proposition merely to the viscera of organic life. Now it may also be extended to the organs of animal life. A violent expenditure of nervous power may relieve the brain or spinal cord, and delirium and convulsions prevent or modify organic changes, just as secre-

tion from the lung or bowels may prevent ulceration.

I have said that the brain might be relieved by convulsions. Let us, holding this assertion in view, compare the phenomena and results of apoplexy with those of epilepsy. In the first place, it is to be remarked that the earlier phenomena of both are the same, namely, an active congestion of the vessels of the head. Any one who has seen the first stage of both must admit this. But let us follow them up through their remaining stages. In the one we have the determination to the head followed by convulsions more or less violent and protracted, which, however, subside after some time, and the patient gets well; in the other there is either death from the violent determination of blood and probable effusion, or, if the patient recovers, there is very often paralysis, showing that injury has been done to the substance of the brain. Now, here we perceive that the case of determination without convulsions is that in which there is either death or recovery with paralysis; there are no such bad consequences to be dreaded where the determination to the head is followed by convulsive fits. In apoplexy we have congestion followed by death, or recovery with paralysis; in epilepsy we have congestion, convulsions, and relief. It is plain that, if we admit the identity of the phenomena in the early periods of both, we must then also admit that the only cause of relief we can ascertain is convulsions. This idea of the subject will explain how it is, that a man may continue for years subject to repeated attacks of cerebral congestion, and yet continue to enjoy tolerable health. It will also explain why it is unnecessary and sometimes even dangerous to bleed in epilepsy. It also shows why it is so often unaccompanied by paralysis, because the brain is relieved by the expenditure of its nervous energy on the muscular system. I think we should generally look upon the occurrence of convulsions, in a case of cerebro-spinal irritation, in the light of an attempt at a crisis made by nature itself. What is a crisis? An organ labouring under irritation is suddenly relieved by a new process taking place, either in itself or in some other part; and when we come to examine what these modes of relief are, we find them to consist in the occurrence of supersecretion, hæmorrhage, exanthematous eruptions on the surface, or convulsions. There is no doubt that when we look to the results of the sudden supervention of a copious secretion in an inflammatory affection of any secreting organ, the source of relief is manifest. If we take two cases of hepatitis or bronchitis, one attended with copious secretion, the other without any secretion at all, it will be easy to conceive how much more dangerous the latter is, and how much more difficult to manage. Now, if we consider the brain in this point of view, we find that it is not a secreting organ, in the ordinary acceptation, and that the only mode in which it can relieve itself is by the expen-

diture of its excess of nervous energy on the muscular system, or by the same expenditure of mental energy, as in the case of high delirium. I think we might fairly draw an analogy between this mode of relief and that which in other diseases is the result of hæmorrhage or secretion. One fact, at all events, appears certain, that in two most remarkable cases of different diseases, each, however, characterised by the same phenomena in the early stage, namely, active determination to the head, we find that the case which turns out favourably is that in which convulsions occur (namely, epilepsy); while, in apoplexy, where these symptoms are absent, we have either death or recovery with paralysis.

If this opinion be well grounded, it would militate strongly against the practice of checking the convulsions of meningitis by opiates. I feel convinced that this practice is wrong and dangerous. Its effects may be as injurious as the arresting the reactions by astringents in a case of acute inflammation. There are two ways in which we can explain its bad effects. In the first place, opiates prove detrimental by checking the convulsions, which appear to be a mode of relief adopted by nature; and, next, they must do mischief from their well-known tendency to add to the existing cerebral congestion. I have now seen a good many cases of meningeal inflammation, in which convulsions took place, and where opiates were employed to remove them, and feel compelled to state that the opium has certainly relieved the convulsions, but the patients have afterwards fallen into a state of profound coma, from which they never recovered. I have witnessed this so often, that I should not discharge my duty properly, did I not warn you against the employment of opium in arachnitis. The same rule most commonly holds good in cases of visceral inflammation, where an organ is in a state of irritation, and has its secretions suppressed. Here also opium, by arresting secretion and increasing congestion, will be productive of bad effects. I allude here particularly to the treatment of pneumonia by opium, as recommended by Dr. Armstrong, who lays great stress upon its use in full doses after having premised a single bleeding. I have had some experience of this mode of treatment, and find that the effect of the opium is, not to remove, but to convert a manifest into a latent disease. I have seen the pain, dyspnoea, and cough subside, but the fever continued, and the destructive process of the lung went on as usual. This is the result of my experience.

I shall now make a few observations on the occurrence of delirium in disease of the brain. In one of my former lectures I alluded to the important fact, that in the majority of cases of meningitis, where delirium was present, there was inflammation of the convexity of the brain. I stated also, that, when inflammation attacked the base of the brain, we might have it going through all its stages

without delirium, and pointed out the importance of this in favour of the phrenological doctrines. Andral admits the occurrence of delirium in case of inflammation on the convexity of the brain, but his reasoning upon this subject appears to me to be inconclusive. He divides affections of the convexity of the brain into those which are characterised by delirium through their whole course, and those in which coma is the most remarkable feature, and seems to think that where coma is the most remarkable symptom, the results of the case are unfavourable to phrenology. But we shall find on examining these cases, that in many of them, where coma was the predominant feature, there had been delirium in the commencement. He gives the details of thirty-nine cases accompanied by delirium all through, in thirty-six of which there was disease of the convexity of the brain, either simple or complicated with arachnitis. As far then as his first set of cases go, they are in favour of the opinion that inflammation of the convexity of the brain is most commonly attended by delirium. It appears also, that those cases in which coma was the most remarkable symptom, there was more or less delirium in the commencement; so that whether we take the cases in which there was delirium all through, or those in which there was coma, the conclusions appear to be in favour of the doctrines of phrenology.

I shall now proceed to make some remarks on the phenomena of organic life in cases of cerebral inflammation. In the first place, with respect to the tongue, we find that in simple arachnitis it is but slightly affected; there may be some trifling degree of foulness, or it may be quite clean and moist. You will observe the value of this, as connected with the diagnosis of irritation of the brain from disease of the digestive system. There are many cases of irritation of the digestive system putting on the semblance of hydrocephalus to such a degree, as even to mislead an experienced practitioner. Now, if it be true that in simple arachnitis the tongue remains clean, it furnishes us with very material information, as, under such circumstances, our attention will be directed to the true seat of disease. Andral says, that in some cases of arachnitis he has found the tongue red, or dry, or foul, but that at the same time there was disease of the digestive system. The majority of his cases, however, were simple, and exhibited no marks of an affection of the tongue or digestive system.

There is one more symptom on which I wish to offer a few observations, and that is the occurrence of vomiting in the hydrocephalus of children. In all cases where there is obstinate vomiting, particularly in children, you should have your suspicions roused, and look carefully to the state of the head. Vomiting is a symptom which occurs in many cases of arachnitis; in some it is slight, in others more constant, while in a third class it

is harassing, incessant, and produced by swallowing the most unirritating substances. The nature of the fluid rejected from the stomach is various, being sometimes bilious, sometimes mucous, sometimes only consisting of what has been recently drunk. In some of these cases you will find the symptoms of incessant vomiting, unaccompanied by pain of the stomach, tenderness of the epigastrium, or any other sign of disease of the digestive system. I have even seen it co-existing with a good appetite. Many persons have been lost by such cases having been mistaken for disease of the digestive system, the practitioner being ignorant that vomiting was here only symptomatic of disease of the brain. No matter what the situation of the meningitis may be, it is now established that you may have vomiting as a common symptom. I recollect the case of a delicate child, about seven years of age, who laboured for some time under catarrhal fever, on the subsidence of which she got an attack of vomiting, which came on at different times in the day, but without headach, delirium, or intolerance of light. This vomiting continued from day to day; and, at the end of a week, the pupils became suddenly dilated, and coma set in, under which she died. There is one very remarkable circumstance connected with this subject, with which I am anxious you should be acquainted. *Where this incessant vomiting is present, you will have the other symptoms of meningitis more or less latent.* This illustrates a law before alluded to, that where the phenomena which are the result of sympathy with an affected organ are very prominent, those which characterise the disease of the organ itself are more or less latent. If we take the reverse of the former case, and consider a case of gastric disease, we know that the irritation of the stomach will produce violent cerebral symptoms, and that here also the same law is exemplified, for we shall have absence of pain, tenderness, and vomiting. The great value of this rule is, that a knowledge of it will put you on your guard, and that the mere absence of the peculiar symptoms of an affection of an organ possessing extensive sympathies, should not lead you to conclude that there was no disease of that organ. In some remarkable cases of gastritis, the principal symptoms observed were convulsions and delirium; there was no vomiting or thirst, very little pain on pressure, and nothing remarkable in the condition of the tongue. The same latency of inflammatory disease is frequently seen in cases of delirium tremens.

With respect to respiration and the state of the pulse in meningitis, there is very little to be said. You may have meningeal inflammation with every variety of pulse, strong, weak, full, rapid, slow, or intermittent. Generally speaking, the pulse is, towards the close of the disease, feeble and intermitting, but you may have the disease running through all its stages without any peculiarity in the character of the

pulse. Respiration seems to be very little affected, and this would appear to favour the opinions of Sir Charles Bell. There is no doubt, at least, that the sympathy of the brain with the respiratory system is much weaker than with the digestive.

Treatment of Hydrocephalus.—I shall occupy your time but very briefly on the treatment of the hydrocephalus of children, as it appears to me to be a disease in which, of all others, the principles of treatment are most simple. The old idea of this affection was, that it was a species of dropsy, depending on a relaxed state of the cerebral vessels, and hence the term hydrocephalus. Modern pathology has shewn that the occurrence of serous effusion is a mere accidental circumstance, as it is present in one case of arachnitis, and absent in another. When it does occur, however, *it is the result of inflammatory disease*, and it is to the prevention and cure of this that the practitioner must direct his attention. With the symptoms of this disease, I shall not take up your time, as you will find them sufficiently detailed in books; but with respect to treatment, I shall say that hydrocephalus is a disease *much more* under the influence of treatment than persons generally think. It is said that, when once effusion has taken place, the case is hopeless, and nothing can be done. This remark appears to me to be unnecessary, for there is no symptom from which you can venture to assert that *effusion* has set in. You may, from the inflammatory state of the brain, have delirium, coma, deafness, blindness, and paralysis, without any effusion of serum, and in many cases life has been saved, even after the appearance of all these symptoms.

This term *effusion* is one of the bugbears of medicine. Many patients are lost from the prevalence of false ideas connected with this subject; for as soon as *effusion* is supposed to have set in, the efforts of the practitioner are given up. Hundreds of patients die of bronchitis and pneumonia, in whom life might be saved if the symptoms of *effusion* had been treated for those of inflammation; and so it is with respect to the brain. This effusion is not the disease; it is not even a constant result of the disease. We have no certain means of ascertaining its existence; and we know, that, by a persistence in antiphlogistic treatment, life may be often saved, even after all the supposed symptoms have occurred.

Gentlemen, take this with you as a rule in medicine,—always to keep your eye more upon the causes than the effects of disease.

The treatment of hydrocephalus in the child should always be active, and conducted on the same principles as those of general encephalitis in the adult. Shaving the head, bleeding when practicable, *repeated leeching*, *cold affusion*, *calomel*, and *purgatives*,—these are the great measures upon which we are to rely for success. It is satisfactory too to reflect, that many cases have been saved by the

prompt and steady adoption of this simple mode of treatment.

Of Internal Remedies.—The use of mercury seems to be that on which you should most rely. Some of the most singular recoveries have occurred after ptyalism has been produced. Let me remind you, however, that the rules connected with this mode of treatment, which I pointed out in speaking of hepatitis, apply equally in this case. There is a terrible consequence of mercurial action in the lymphatic temperament with which you should be acquainted,—I allude to a violent and destructive inflammation of the soft parts of the mouth and face, which has got the name of the *mercurial cancrum oris*. An oedematous inflammation of the cheeks, lips, and tongue, takes place, and, if not checked, rapidly runs on to extensive ulceration. I have seen one cheek, half of the nose, the lower eyelid, and the opposite angle of the mouth, utterly destroyed, in a case where but five grains of calomel were used. This drawing represents the disease, after a frightful perforation of the cheek. In this case the quantity used was nine grains. I have seen the disease from the use of so small a quantity as a grain and a half of calomel! These facts shew that there is a state of the constitution in which a minute dose of calomel may have terrible effects. The same too may arise from the external use of mercury. I recollect the case of a young woman in the Meath Hospital, whose head was rubbed with *one drachm* only of mercurial ointment, for the purpose of destroying vermin. She was attacked, and with difficulty saved.

The disease may also come on suddenly in a patient who has been for some time using mercury in considerable doses; but this is the rarest case.

You recognise this disease by the sudden supervention of great swelling of the lips and cheeks, so as to completely alter the expression. The tongue is also swollen. All these parts are hot and tender to pressure. The breath is foetid, and the internal surface of the mouth excoriated, and often covered here and there with patches of lymph. At other times we have a circumscribed oedematous swelling, occupying the centre of the cheek, which runs on to ulceration; but most commonly the ulceration of the external parts begins at the depending angle of the mouth.

Gentlemen, in a case of this kind, if you are called before ulceration has taken place, I believe you can often save your patient, and prevent destruction of the face. Treat the disease as a violent inflammation. Use repeated leeching, poulticing, and the warm bath. *While you do this, you must keep up your patient's strength by light nourishment and wine.* Apply to the internal ulcerations the mel seruginis, the nitrate of silver, or the chloride of soda. I have now saved many cases by bold and repeated leeching. I remember one case of a man in which

ninety leeches were used: he recovered perfectly.

In the treatment of this affection, it is of the utmost consequence to attend to the position of the patient. By keeping him as much as possible upright, or by preventing him leaning constantly on one side, we do much to prevent the occurrence of the ulceration of the angle of the mouth.

As far as I can see, hydrocephalus, when taken in time, is a very manageable disease; and there is only one case in which it is difficult to treat, and that is where the cerebral affection is accompanied by symptoms of gastro-enteric disease. In several cases of hydrocephalus, this complication certainly exists; and you have first symptoms of disease of the digestive tube, and then of the head. Such cases as these are involved in great difficulty, and in their treatment you run the hazard of falling into a twofold mistake. The first is your acting on the supposition that the disease of the head is only sympathetic, and that it will subside as soon as the abdominal symptoms are removed; the other is occupying your attention exclusively with the head. Now there is one rule with respect to this, which I think will serve to guide you through many difficulties, *and this is, never to neglect the head.* Though you have first an affection of the digestive system, and then of the head, it is better (even though the symptoms of the latter still continue) to pay attention to the head. You can do this at the same time that you are attentive to the condition of the digestive organs. Another rule is, that the cases of disease in which the purgative plan does not answer are generally those in which there is primary inflammation of the digestive tube. Dr. Cheyne, in speaking of the treatment of hydrocephalus, says, that some cases are benefited by purgatives, others not; and that the latter are those in which there is disease of the intestinal canal. In such cases you will not irritate the bowels, or add to the existing inflammation by purgatives. Let the bowels be kept open by enemata, and direct your attention immediately to the head. Children with largely developed heads, and of a strumous diathesis, are very subject to this disease; and I feel convinced that the present rage for the early mental education of children has a strong tendency to produce it in subjects of this description. I believe there are many cases of fatal hydrocephalus, from which the poor victims would have escaped but for the pernicious efforts of the parents to make them literary prodigies. I have observed many cases of this kind among the children of persons who, having been originally situated in an humble sphere, and deprived of the benefits of education, accumulate wealth, and then, feeling in their new condition the want of education, are anxious to communicate it to their offspring; and with that view have them educated with too much care and from too early a period. The child

is constantly kept at his books, his little mind is perpetually tasked, a degree of cerebral excitement is kept up, and while he is delighting his gratified parents with the manifestations of a precocious intellect, his health is neglected, and the seeds of disease are insensibly sown. One of the most ordinary consequences of this early application of the mental powers is hydrocephalus. These little creatures, too, have a congenital disposition to disease of the brain, for they have generally large heads. Such cases are examples of the results of an arrest of development. A relative condition of head exists similar to that which occurs during foetal life, and this is always accompanied by a remarkable susceptibility to inflammation. This peculiar development of head also produces a precocious state of intellect, which is increased by the pernicious habit of obliging children to study at too early an age. Where you meet with children suffering under these circumstances, you will not discharge your duty properly if you do not point out to the parents the mischievous tendency of their conduct. In such cases as these it may be justly said that ignorance is bliss.

CLINICAL LECTURES

ON THE

SURGICAL ANATOMY AND TREATMENT OF
THE UTERUS AND ITS APPENDAGES.

BY M. LISFRANC,

PRINCIPAL SURGEON OF THE HOSPITAL OF
LA PITIE, PARIS.

LECTURE IV.

*Peculiar Tumour of the Uterus—Polypi—
Ulcerations—Simple Ulcerations—Ulce-
rations succeeding Tubercles—Fungous
Tumours—Ulcerations and Carcinomatous
Vegetations.*

GENTLEMEN,—In order to complete my description of the affections of the uterus, it remains for me to add a few remarks relative to a peculiar species of uterine tumour, and to describe the polypi of which this organ is the seat.

A Particular Species of Uterine Tumour.

—There exists a tumour, the nature of which is little known, which develops itself in the substance of the parietes of the uterus, and to which it is necessary for me to draw your attention. The ordinary seat of this tumour is at the inferior portion of the posterior uterine wall. If the finger be introduced through the dilated cervix into the cavity of the womb, you will feel on a point, the extent of which varies from the diameter of a shilling to a crown piece, a projecting round, and more or less circumscribed tumour, imbedded in the uterine parietes, and resembling one of those marbles with which children play, and of which the half only will be protuberant.

It neither possesses the softness of a vascular, nor the hardness of a fibrous polypus. It is sometimes found insensible to the touch, at others the contact of the finger produces acute pain; its shape scarcely ever varies; but in one female I found it in the form of a cock's spur. The remainder of the organ is healthy in general. Is this tumour carcinomatous, or is it only the result of partial inflammation of the uterus, or a white point indurated scirrhus? Is it a polypus, a cyst, a cartilaginous, or osseous concretion? Pathological anatomy has shown the alternate existence of these different productions in the uterus, but, as regards the tumour which is now under consideration, it is necessary to avow that the examination on the living will not suffice to affirm its nature.

In this case the indications are limited to two kinds, viz. to combat the sub-inflammation, if it exists, and when it has disappeared, to have recourse to discutients, proceeding however, with a prudent reserve.

These tumours are considered as necessarily fatal, but I am not of this opinion. I have attended a great number of females labouring under this affection, and by arresting the inflammation, I have frequently prevented their degeneration; they sometimes disappear entirely, in other cases they become small and indolent, and no longer exercise an influence on the general health. They still retain, however, during a long time, a disposition to become again affected with irritation; their cause is an inflammation which must be combated by the means I have already described.

Uterine Polypi.—The nature of uterine polypi has been more correctly investigated than that of any other affection of these parts, and more particularly by Malgaigne*, I shall, therefore, only dwell on those points, which are either the least known or completely new.

The two most frequent varieties of these polypi are the cellulo-vascular, and the fibrous; the first are constantly seated either at the inferior portion of the uterine neck, between its two labia, or at the inferior part of the internal surface of the uterus. They are, in general, of little volume, single or multiplied, and present the form of granulations which are sometimes immovable, and broad at their base, but they are commonly attached to the extremity of a more or less elongated pedicle. In the latter case it is somewhat difficult to recognise them on examination, particularly when the pedicle is inserted above the cervix, as they then recede from the finger into the interior of the womb. It is necessary to introduce the finger into this organ, which manœuvre is generally permitted by the sufficiently dilated neck.

In order to remove them you must dilate the vagina by the aid of a speculum, cleanse the parts with a camel's hair pencil, and seize

* See Des Polypes Uterins, 2nd edition, 1833.

the polypus with a pair of long forceps, twist it round several times, and afterwards tear it away. The only precaution necessary to be observed is, to seize the polypus near its root, in order to be sure of completing its total extirpation; the operation has succeeded if a slight depression be perceptible to the finger at the spot from which the pedicle had grown.

These polypi are frequently accompanied with hypertrophy, oedema of the uterine neck, and engorgement of the womb itself. Thus, all is not finished after the operation has been performed. The resulting wound forms an additional cause of irritation to the already diseased organ. It is, therefore, proper to ascertain, eight or ten days after the removal of these bodies, how far cicatrisation has advanced: this process encounters the same difficulties in its completion as after the amputation of the uterine neck.

In fibrous polypi I recommend you to exercise torsion only, when they possess a very slender pedicle. The ligature appears to me to be an inappropriate agent, and should be employed only as a last resource: the operation which ought to be preferred is excision. Most of you know in what manner excision is performed;—the polypus is seized with a pair of forceps, and lowered to such an extent so that the uterine neck presents itself at the vulva. Then, if it be necessary, the finger is introduced, and a pair of curved scissors (which suffice to make the section) conducted along it as far as the pedicle. When the root of the tumour is seated too high in the uterine cavity, you must incise the cervix itself, which division subsequently affords every facility to the operator. There is nothing to be feared from hæmorrhage; I have never seen more than a few spoonfuls of blood flow after the excision of these bodies, and plugging would be the certain means of arresting it in every case.

But, occasionally, when we attempt to draw down the polypus, it is found too soft, and tears under the action of the forceps. This circumstance would appear to render the excision performed in the ordinary manner impossible. It is no longer the polypus which ought to be seized in these cases, but the uterine neck itself. A few little punctures made in this organ by the forceps of Museux excite unnecessary alarm. It is known that the application of leeches to this part is unattended by pain, and even the amputation of the uterine neck is not a severe operation. Pressure alone appears endowed with the property of producing an acute sensibility on this organ, a phenomenon which is very remarkable, but not without analogy in the economy. I shall now, gentlemen, adduce certain facts in support of this new mode of proceeding.

A few months since I was called to visit a young female in the Rue des Cherche-midi, who had experienced a considerable flooding fifteen days after a favourable accouchement. The hæmorrhage had so greatly deteriorated the health of the patient by its continued repe-

titions, at certain intervals, that when I was consulted she was in a state of apparent death. MM. Andral, Bouillaud, and Hatin, had been already simultaneously consulted. I recognised the presence of a polypus, attached by a broad base to the fundus of the uterine cavity. No time was to be lost, consequently an operation was immediately resolved on. But the tumour was soft, spongy, and tore on the slightest effort that was made to exercise a traction upon it. I seized the cervix uteri with the forceps and brought it to the vulva. The research now became facilitated; the finger was enabled to traverse the entire base of the polypus; and, taking into consideration the dilatation of the uterus, and the debility of the patient, I gave the preference to the ligature, which was placed by means of the instruments of Levret. The thread was scarcely tightened before the blood ceased to flow. The following morning the pulse was increased in strength and fulness, and I was enabled to have recourse to a small bleeding. On the eighth day the polypus came away in a putrefied state, and on the fifteenth, a slight degree of debility being excepted, the patient was perfectly cured. The punctures caused by the forceps did not produce any accident.

A short time after this, the sister of a commander of a garrison in Paris placed herself under my care for an affection of the same nature. She had two polypi inserted contiguously into the interior of the uterus, half an inch above the os tincæ: one was of the size of a large walnut, the other elongated, somewhat flattened, and attached to a very slender pedicle, which glided along the former. I seized the largest with the forceps, and brought it to the vulva. I then insinuated a pair of curved scissors as far as the two pedicles, which I thought to have divided at one cut. But it was not so, as the first polypus was alone excised, whilst the other accompanied the uterus in its ascent. It would have been impossible to have thought of seizing it on account of the tenuity of the pedicle, and it was therefore upon the cervix that I fixed the forceps. In this manner the uterus was brought down to the vulva, the second polypus excised, and in three days the patient was able to walk in the gardens of the Luxembourg.

A question here presents itself which no author that I am aware of, has ever proposed. The polypus being detected, and the urgency of the operation proved, is it necessary to defer it because the female is at the menstrual period? I would answer this question by quoting the following case.

A young female from the south of France came to Paris to be cured of an affection of the uterus, she was unsuccessfully treated during three months, the case being taken for an uterine engorgement, when at length M. Latapie, who visited her in conjunction with two other medical practitioners, requested that I should be called in. I was told that every eight days this woman experienced expul-

sive pains, a symptom which, in these cases, always deserves attention, and which ought invariably to cause the suspicion of the presence of a tumour contained within the cavity of the uterus. On examining her I found the uterine neck dilated, almost obliterated, and on penetrating into the interior of the uterus, and describing with the finger the arches of a circle, in the manner which I have pointed out when speaking of the original examination, I arrived at a rounded body, which projected nearly an inch and a half from the internal surface of this organ. To avoid error, I examined several times. At length, having glided the finger between the tumour and uterine parietes, I was enabled to announce with certitude the existence of a polypus. The patient was ostensibly perishing, and consequently the operation was urgent; but the menses were about to return the next morning, and for this reason I considered a postponement necessary. Hemorrhage supervened, which was followed unfortunately by peritonitis, and the patient was carried off in two days. The autopsy confirmed my diagnosis.

I have since seen in St. Augustin's ward a female die of a metro-peritonitis, which came on during the menstrual discharge. Thus my resolution is fixed not to allow myself for the future to be dissuaded by the presence or approach of the menses from an operation, the urgent necessity of which I have foreseen.

Ulcerations of the Uterus.—I now come to treat of a very important and difficult subject, that is to say, of the ulcerations which declare themselves on the neck or else on the body of the uterus.

For the sake of introducing the necessary order and clearness in the study of these affections, I shall speak successively of redness and phlyctæna of the uterine neck, which frequently precede, and sometimes resemble ulcerations; of ulcerations, properly so called, and scrofulous ulcerations, the result of a degenerate tubercle; fungous tumours which succeed certain ulcerations; and lastly, ulcerations and carcinomatous vegetations.

Redness—Phlyctæna of the Uterine Neck.—You will find in almost every female who is affected with abundant discharge, on the posterior lip of the os tincæ, a redness, which appears owing to the contact of the liquid secreted by the uterus, in the same manner as in epiphora the tears cause a redness and excoriation on the skin of the cheeks. This redness in itself is only of very slight importance, but the mucous membrane may finally become diseased, if the catarrh, which is the exciting cause, be not cured.

But there is another species of this affection which is entirely independent of this cause, and shows itself on a portion or on the totality of the uterine neck, although the vagina may not have lost its natural colour; it resembles the blotches produced on the skin by a cutaneous disease, its reddish-brown colour an-

nounces the presence of inflammation; it is slightly elevated above the remaining healthy portions of the cervix, is sometimes disposed in isolated spots, and as neatly circumscribed as if made with a punch. I have seen them in some females formed by an interlacement of little prominent vessels, in the same way as is observed in inflammation of the fauces. They are accompanied in every case by simple engorgement, seldom, however, by induration of the cervix uteri, the mucous membrane in general being found on examination soft, thickened, villous, downy, and bleeding with the greatest facility.

These red patches, which frequently terminate in the production of ulcerations, deserve particularly to be attended to. If they are accompanied with smarting, heat, pain, you must have recourse to antiphlogistics, general baths, injections, glysters, and emollient drinks. If there exist acute suffering, it must be combated by narcotics and revulsive bleedings from the arm. When all these symptoms of irritation have disappeared, these blotches occasionally become in the course of time spontaneously dispersed, but more frequently, however, the least exercise, coitus, or the use of excitants, re-produces the acute stage accompanied with all its phenomena. You must not therefore be lulled into a deceitful security, and believe the cure complete because the affection has arrived at its chronic period. Antiphlogistics, then, are no longer useful; the case requires the application of astringents on the diseased part. But the mode of their employment is not indifferent; some practitioners introduce daily, by the aid of the speculum, a piece of lint imbibed in liquid; but this is a powerful source of irritation, and at most is only suited to girls of the town, whose vaginæ, being so accustomed to the contact of foreign bodies, have lost the greater part of their sensibility. Injections possess another inconvenience, for when very active they irritate the mucous membrane of the parts, and when less weak they do not exert a sufficient action on the uterine neck. The remedy which is by far the best, and that which frequently succeeds in its first application, is a slight cauterisation made with the nitrate of mercury. You should previously cleanse with a very soft camel's hair pencil the affected surfaces, to remove the mucosities, which would prevent the action of the acid, and afterwards touch the parts very gently, in such a manner as to whiten only the blotches; and it very often happens that eight days suffice to obtain a perfect cure.

You will also frequently observe on the uterine neck little white miliary vesicles, which are distinct or confluent, and are sometimes limited to a portion of this organ, whilst at others they occupy its entire surface. After they have burst, these vesicles leave little superficial ulcerations, which frequently unite together, and form rather extensive excoriations. At other times there is found

upon these parts a number of pimples, which resemble aphthæ; in such cases also I prefer the cauterisation with the nitrate of mercury, as the surest means of dissipating the accidents and preventing the formation of ulcerations.

2. *Simple Ulcerations.*—Before proceeding further I would remark to you, that as the inferior lip is more frequently than the other the seat of inflammation, eruptions, and ulcerations, you may likewise observe a similar predilection as regards the posterior margin of the cervix uteri. It is this portion which is attacked, as it were, in preference by the red patches, phlyctæna, and excoriations. Nevertheless ulcerations are likewise seen to show themselves elsewhere, as, for example, between the labia of the os tincæ, where they escape the eye if the precaution of raising its anterior wall be not observed.

They are also occasionally found as far as the inferior portion of the uterine cavity, and here the vaginal examination alone is capable of indicating their presence.

The cervix is in general sufficiently dilated to permit the penetration of the finger, which instead of encountering that smooth polished surface similar to a serous membrane, which the interior of the uterus presents in a state of health, perceives a thickened and villous state of the parts, and is frequently stained with blood, however delicately the examination may have been performed. Hence it is impossible to be mistaken as regards the alteration, however difficult it may be to ascertain precisely its extent.

Ulcerations show themselves in different forms; sometimes they are limited to simple excoriations, at others they present a slight excavation. The mucous membranes in numerous instances, being increased in thickness, their tumefied, projecting, and perpendicular edges make them appear deeper than they are in reality. Their base is sometimes irritated, traversed by numerous fissures, and may be compared to a dog's skin; at others it is covered with fleshy granulations, which, in some cases assume a fungoid appearance, and has hence caused some inexperienced surgeons to believe in the existence of carcinoma.

It is not always easy to distinguish a simple redness from an excoriation. The side view of an object seated at the bottom of the speculum is almost altogether impossible, whilst a full view of the parts is liable in this case to induce into error. You will readily perceive, however, how important this diagnosis may be: for example, in a case of cicatrix resulting from the amputation of the cervix. A very valuable sign, and one which has never deceived me, is the following:—Pass a piece of fine lint gently over the diseased spot; if it be a redness, this will not produce any effect; but if it be an ulceration, it will render a small quantity of blood perceptible.

There are superficial ulcerations which bleed with the greatest facility, and consequently it is necessary to notice them. This symptom

indicates, in the first place, that the uterus is gorged with blood, no matter what may be the cause, since that which is the most to be dreaded is the development of a varicose tumour, which I shall describe presently. The slightest excoriations, with or without induration, occasion in other females nearly all the symptoms which characterise cancer. I have had the anatomical proof of the simplicity of these ulcerations during the cholera. Many of my patients having fallen victims to this disease, the uterine neck was the object of the most minute research. I found the mucous membrane red, softened, and somewhat fungous, the ulceration very superficial, and beneath it the uterine tissue was sometimes superficially altered in texture, and allowed itself to be readily torn; occasionally, however, it was perfectly healthy.

The principal therapeutic agent to be employed in cases of simple ulcerations is cauterisation, but it requires a certain condition of the parts to enable it to succeed. If, for example, there exists either a partial or general tumefaction of the uterus, to such an extent as to render the volume of the affected portion double, I strictly forbid its employment. I have seen the opposite precepts adopted a great number of times, in which cauterisation has been almost invariably followed by metritis, or metro-peritonitis. Death has sometimes supervened; and it is this circumstance which has caused numerous medical practitioners to reject a remedy, which their inexperience alone had rendered dangerous. Lastly, cauterisation has hastened the degeneration of the organ in the most favourable cases. Thus, I lay it down as a rule, that a considerable engorgement is a counter-indication to cauterisation, whilst one of a slighter description may permit its employment. It is therefore necessary, in the first instance, to direct your attention to the treatment of the tumefaction. The second exception is in those cases in which a superficial ulceration makes progress in spite of the employment of medicinal means.

Here you may hazard cauterisation, although it must be performed with caution, and with that promptitude in the suppression of those resulting accidents which I have just enumerated. Inflammation of the vagina or cervix, and even acute pain, are counter indications. Lastly, it is necessary to abstain from its use four or five days before the expected appearance of the menses, as well as during the period of their discharge, and three or four days after their suppression, so as not to subjoin an artificial excitement to that of which the uterus is then the seat.

The manner in which the caustic should be applied is very important; cauterisation has been for a long time injured by imprudent manœuvres. Thus some practitioners place plugs of lint imbibed in the nitrate of mercury upon the uterine neck, retaining them in this situation during eight or ten minutes, whilst

others employ a conical piece of potassa fusa. What could we expect from such unscientific means, except that which actually occurs, viz. dreadful and even fatal inflammations, perforations and obliteration of the vagina? I have adapted the means proposed by M. Alibert for the cauterisation of corroding cutaneous affections, to the ulcers of the uterine neck, namely, to attack the superficies, not so much with the intention of destroying the tissues as with the idea of changing their action. Thus you have often observed me in this hospital perform even a partial cauterisation on external ulcers, which has sufficed to modify their entire surface.

The following is, then, the manner which I adopt:—after having introduced the speculum, I remove the mucosities by the means of a fine camel-hair pencil. If a small quantity of blood flow from the ulcerations, I inject some cold water, and, if this does not suffice, I cauterise the bleeding surface, and when the blood is arrested, I remove the clot which covers the ulceration, in order to apply the nitrate of mercury to the tissues themselves. For this purpose I use the smallest camel-hair pencil employed by miniature painters, and, after having touched the ulcerations, I throw cold water into the speculum by means of a syringe, in order to arrest the action of the caustic, and to prevent its extension beyond the diseased surfaces. This lotion being continued for about a minute, the speculum should be withdrawn. The proto-nitrate of mercury is, according to my experience, the best form of caustic that can be employed in these affections, as, from numerous trials of this preparation, I have always found it the most successful. In my opinion, it is much more preferable to the nitrate of silver, which has a tendency to reproduce the menstrual discharge; but it is impossible to detect a satisfactory explanation of this phenomenon.

The result of cicatrisation is not invariably the same in every female. In general, it is not even perceptible; but in some cases it causes, on the contrary, acute suffering. In some instances, however, it commences only at the expiration of the fourth, fifth, or sixth application. Can this be attributed to the circumstance that the substance employed had only exerted, in the first place, its action on the diseased tissues, but that it had afterwards attained it, when returned to their healthy, and, consequently, more sensible condition? In general, however, pain supervenes at the expiration of an hour or two after the operation; or, if it had already existed, an exasperation ensues, the patient experiencing a sense of smarting in the vicinity of the uterus and lumbar region, which continues for a time rarely exceeding twenty-four hours. The pains are already calmed by the exhibition of tepid emollient injections, small clysters made with a decoction of linseed meal and poppy-heads, warm baths protracted to the time previously designated, and, as a last re-

source, a general revulsive bleeding from the arm. I have never witnessed, in the immense number of females whom I have cauterised up to the present moment, any symptoms that might have deserved the appellation of serious. Cauterisation is much more painful in tempestuous weather, or, in other words, during the atmospheric variations, since it is well known, that these circumstances produce in females, especially those endowed with a highly sensible temperament, a peculiar influence; and there are some that never support its employment; this, however, is rare, as I have never seen but two examples.

After a suitable exhibition of baths, emollients, sanguine emissions, narcotics, &c., and the pains had disappeared, and every thing seemed to indicate the propriety of cauterisation; this operation caused the reproduction of the symptoms, acute pains, sensations of heat, nervous excitability, and even diarrhoea, so that in these two females it was necessary to abstain altogether from the employment of this means. Another anomaly, which is less rare, but very remarkable, is that a female, who has suffered greatly from the first cauterisation, does not experience any pain from the second, performed eight days after, and *vice versa*. I have often observed this fact, but cannot explain it, however, in a satisfactory manner.

Cauterisation should in general be repeated every eight days, but if the pain caused by the caustic is very acute, you must wait ten or twelve days before you attempt to renew its application. But at what epoch shall we judge that the cauterisations are sufficient, and that we can abstain from their use?

This remedy is intended to modify the surface of the ulcer, to disperse the hardness or simple hypertrophy which occupies its circumference, and to repress the luxuriant granulations. If after two or three applications of the nitrate of mercury these results be obtained, and if cicatrisation proceed from the circumference towards the centre, the latter point should alone be touched; and frequently after the fourth or fifth time, all is finished. But very often, after the fifth or sixth application, the cicatrice suddenly remains stationary, in this case you are recommended to continue, and even I participated for a long time in this error, until I was undeceived by the following circumstances. During the three diseases with which I have been attacked, I ceased for a month or more to cauterise my patients; on seeing them again, I found some completely well, whilst others were in a state of incipient convalescence. These observations did not fail to impress on my mind the necessity of adopting in future the following line of conduct:—after five or six applications, when the luxuriant granulations, induration, and violet colour no longer exist, or, in a word, when the ulcer presents a healthy aspect, I suspend the cauterisation, whether the process of cicatrisation be going on or not;

and during three or four days I prescribe emollient injections, which I afterwards replace by the use of remedies of a more healthy nature.

It would first appear that the chloruret of the oxide of sodium ought to afford the same result here, as that which we obtain from the use of this substance in ulcers of the leg. But it is not so; this preparation has completely failed, after numerous trials that were commenced with the greatest expectation of success. I have likewise employed decoctions of the cortex *Punic. granit.* of the *rosa Gallica*, but without deriving any benefit from their use. Lastly, I have had recourse to an infusion of *cinchona*, in the proportion of 3j. to a pint of water, gradually increasing the quantity, and substituting the decoction for the infusion, in order to augment still more its energy; this liquid thus employed appears to me to be endowed with the most suitable cicatrising properties. A few days have sufficed to heal ulcers, which have resisted all other means. These injections may cause heat and slight smarting during five or ten minutes: this symptom is scarcely worthy of notice; but if these sensations continue for a longer space of time, you must dilute the solution with water, or even suspend its use.

Thus, when cicatrization has not sufficed, you may have recourse successfully to the injections I have just indicated; and if, as it sometimes happens, cicatrization does not go on, under their influence, you must cease to employ them for a few days, and return to the use of the nitrate of mercury, which, under these circumstances, scarcely ever fails to produce beneficial results. It would appear that, in these cases, the *cinchona* has so modified the tissues, that the action of the caustic is rendered more efficacious, and, in fact, it is observed that it promotes the development of fresh granulations.

The time necessary to obtain a perfect cicatrix is very variable, and difficult to be foretold with anything like precision. Some females are cured in fifteen days or a month, whilst others require from three to five months, or even more.

It is not uncommon to see white spots declare themselves after the ulcers have been healed; but, in general, the cicatrix remains of a reddish colour, which circumstance may cause you to believe in the existence of a very superficial ulceration. As it is, as I have before stated, almost impossible to obtain a side view of the parts by means of the speculum, it is necessary, in order to give a certain diagnosis, to have recourse to the means already indicated, namely, to touch the wound with a piece of lint to see if it bleeds or not. Thus it is seen that the treatment of ulcerations presents numerous indications, which it is essential to expose in the manner I have adopted. I have recommended cauterisation as a general remedy; I do not mean to state, however, that there are not occasionally found

cases in which antiphlogistics and revulsives have alone sufficed to effect a cure; but these are so extremely rare, that I esteem their proportion as 1 to 100. If, nevertheless, cicatrization advances by the use of these means, it would be unquestionably useless to employ cauterisation.

Scrofulous Ulcerations.—I thus name the ulcerations which succeed the suppuration of tubercles occupying the uterine neck. In the five or six cases of this description that I have met with, the general temperament of the patients, and the escape through a small aperture of a caseous matter, analogous to that which is furnished by the cervical ganglia in a state of suppuration, did not leave scarcely any doubt as regards the diagnosis. You have seen, in St. Augustin's Ward, one of the females in whom, in proportion as the cervix entered the speculum, the pressure of this instrument caused the escape of a caseous matter, through a little orifice, which communicated with an abscess situated in the parietes of the uterus. This female was cured, became pregnant, and was safely delivered. You are daily in the habit of seeing the nurse, who is in the same ward: she had an uterus enormously distended by a tubercular abscess, seated in the posterior parietes; this abscess burst externally, and after two years' treatment, she enjoys a state of health of which you are all capable of judging.

Tubercular abscesses in general proceed in the same way as those of a common nature; the finger is capable of feeling a fluctuation, and an opening can be made by means of a bistoury.

These narrow and fistulous apertures insensibly enlarge; their margins, destroyed by ulceration, soon leave the bottom of the cyst exposed, which appears greyish-pale, whilst its edges are uneven, rugged, perpendicular, and allow the abundant discharge of a matter which has a very disagreeable odour, not, however, resembling that of cancer. There occasionally exists at the same time an engorgement of the neck, and even of the uterus itself. This happened in the case of a nurse, in whom, after I had obtained the cicatrization of the parts, there remained a tumefaction of the body of the uterus, which was a long time in subsiding. I even entertained very serious apprehensions for her safety, for if this tumefaction had been owing to the presence of other tubercles, they might have opened into the peritoneum, and have produced fatal accidents.

The uterus is sometimes embossed, which circumstance has more than once caused a belief in a carcinomatous condition, which did not exist. I, as well as many other practitioners, fell into this error, in the case of the nurse in St. Augustin's Ward.

With the exception of lancinating pains, this affection is, in fact, attended by all the symptoms of cancer; and it is only fluctuation that can guide us, at the commencement, to a

direct diagnosis. When the disease is more advanced, it is impossible to be mistaken as to its nature, from the caseous appearance of the discharge, the facility with which the ulcer becomes cleansed, and lastly, on account of the promptitude with which cicatrization is effected.

At the commencement the treatment ought to be directed to the suppression of inflammation, if it exists, taking care, however, to proportion the employment of antiphlogistics to the temperament and force of the patient. You may afterwards prescribe astringents and cauterisation, the beneficial effects of which may be assisted by the internal use of bitters.

Fungous Tumours of the Cervix Uteri.—This disease, which possesses such serious characters, frequently succeeds (as I have already stated) those superficial ulcerations which have a tendency to bleed with the greatest facility. Not many years have elapsed since I had an opportunity of witnessing, in private practice, two females labouring under a similar species of ulceration, which afforded a considerable emission of blood at each introduction of the speculum. Although the finger could not detect the slightest softening of tissue in either of these cases, I still feared the existence of some more serious affection, and consequently proposed cauterisation. This advice was not, however, adopted. On being again requested to visit the patient a short time afterwards, I detected all the characters of a well-defined fungus hæmatodes developed on the uterine neck, and which did not tarry long in causing the death of these two individuals.

Fifteen months since I observed an ulceration presenting a similar predisposition to bleed with facility, in a lady who resides in the vicinity of Paris. I again recommended cauterisation as a necessary remedy; but the practitioner who habitually attended the family did not think himself justified in consenting to its employment. And within these last three months I was again consulted by the patient, when I detected the presence of a fungoid tumour, seated in the uterine neck, the result of which may be easily described.

In these cases, the fungous, or varicose tumour, had passed the limits of the cervix, and had encroached on the superior insertion of the vagina, a circumstance which renders the operation impracticable. Every time then that similar ulcerations may present themselves to your notice, if there be no inflammation, you should immediately cauterise, in order to arrest the progress of such a serious affection.

When a fungous tumour is developed, it is soft, villous, intersected by fissures, and arranged in a series of lobules; it is the seat of a very abundant aluminous exudation, and of serious hæmorrhages, which, however, are generally unaccompanied by pain. What remains to be done, when it has exceeded the limits of amputation? To touch it every eight days with the caustic, so as to retard its pro-

gress. I have often succeeded by these means in prolonging the existence of numerous patients. Compression would prove perhaps advantageous; but I do not know of any case in which it has been tried. Amputation is unquestionably the only efficacious remedy, and you must hasten to have recourse to it, as soon as you have conceived its possibility.

Cancerous Ulcerations and Vegetations.—It now only remains for me to treat of cancer of the uterus, a subject which presents great difficulties, since in no other part does this disease assume such varied forms. Sometimes it commences by ulcerations accompanied with vegetations, fungous excrescences, indurated and scirrhus elevations; at others, the finger can be thrust into the tissue as into a quagmire, from whence it returns impregnated with a most horribly fetid matter.

In these cases, the patient is tormented by pain, diarrhoea, fever, yellowness of the skin, &c. &c. She exhales a characteristic odour, and reveals to every eye the nature of the affection which preys upon her frame, and the proximity of that moment which threatens to terminate her sufferings.

But occasionally this disease is less formidable in its attack, you will only find a dry ulceration, which is unattended by pain, but corrodes the tissues in the same way as phagedænic ulcerations, which are observed on the face. Are these a veritable species of cancer? the answer concerns but little the treatment to be pursued; and in many cases it is necessary to attack the disease with promptitude, for in proportion as it proceeds pains supervene, which become dreadful in the end, especially in females of a nervous temperament. The pains sometimes assume a singular and inexplicable form of intermittence. Thus I have seen them reappear only every five or six weeks. An example of this curious fact may be observed in several unfortunate females in St. Augustin's Ward, whose existence I have prolonged more than two years.

Lastly, the general or partial tumefaction of the uterus may be complicated with vegetations and soft fungous tumours, which are readily torn. They fill the vagina, and even project beyond the vulva, bleed from the slightest touch, and secrete a fluid in such abundance, that I have seen females soil from 50 to 60 napkins a day. This secretion exhales an unpleasant odour, and excoriates the thighs, notwithstanding the precaution has been taken of besmearing them with some oleaginous substance.

It is very remarkable that with the exception of a sense of uneasiness, and weight within the pelvis, and slight pain in the lumbar region, these females do not suffer at all in any other part; the *embonpoint* does not diminish, the freshness of the complexion continues, and this apparently healthy condition conceals from the medical attendant the severity of the affection until the discharge

awakens his suspicion. Have we to deal with a cancer in this instance? But how is it that in this case the local pains are absent? It is true that in general the pains supervene when the affection has existed a long time. It is my opinion that the disease is not cancer at the commencement, but that it possesses a tendency to become so at a later period. I have obtained a cure in three cases of this description. In a lady residing in the Rue St. Lazare, who had been condemned by several practitioners, the fungous tumour fell spontaneously, and has not since reappeared; this female is now enjoying the most perfect state of health.

It is moreover necessary to avow that with the exception of those simple ulcerations, which I described at the commencement of this lecture, and those which result from suppurated tubercles, it is a fact that the differential diagnosis of all the others still remains in the greatest obscurity. Several authors have endeavoured to lay down certain characteristic signs, which, however, are not observable at the bed-side of the patient; but when the disease advances in spite of all our efforts, of what importance is it, whether its carcinomatous nature be demonstrated or not, if the general health be affected, and the progress of the malady can only be arrested by amputation? Thus would I answer those superficial critics who have reproached me with having removed uterine necks in which it was impossible to discover any scirrhus or encephaloid tissue. Ought I to have allowed the disease to increase and become incurable? When every other hope is lost, and an affection exercises a deleterious influence on the economy, it must be removed without delay, whatever may be its nature; this is true surgical philosophy.

When I have to treat diseases which possess a doubtful character, I commence by attacking the engorgement with the hope of reducing its volume; if the female be debilitated from the abundance of the secretion, and from the repeated hæmorrhages which supervene, I have endeavoured to destroy as much as I could of these soft vegetations with the fingers, having recourse afterwards to cauterisation. This remedy has, however, produced inflammatory symptoms, and it became necessary to discontinue its use. In another female it required three years and a half to overcome the disease, but the two last were speedily cured, with the exception of the engorgement, which continued some months.

If these means fail, or if the ulceration be decidedly cancerous, some practitioners recommend cauterisation. You may, without doubt, have recourse to this remedy when the depth and surface of the disease are not very extensive, in the same manner, as you proceed in analogous affections of the skin; but if the disease be deep-seated, and especially if it has attacked the body of the uterus, it would be highly imprudent to think of employing these

means. The only resource then, which art possesses in such cases, is the amputation of the uterine neck.

[We shall here terminate the lectures of M. Lisfranc on this subject. He described at some length, before a numerous class, the surgical anatomy, and the mode of performing the amputation of the cervix uteri, but as we are in hopes of shortly being enabled to give to our readers a paper on this subject by M. Lisfranc himself, we abstain from publishing this part of his course. One word only on the total extirpation of the uterus; M. Lisfranc demonstrated on the dead subject, that, by making a slight incision through the perineum, the uterus descended sufficiently to expose the broad ligaments, thus facilitating the ligature of the artery contained in their substance. By this manoeuvre we are enabled to avoid including the whole of the tissues which constitute these ligaments, one of the most powerful causes of peritonitis after the operation.]

MOST IMPORTANT INQUEST AT YORK:

Verdict—"MANSLAUGHTER," by Morison's Pills.

CONSIDERABLE excitement has prevailed in this city since Friday last, in consequence of the death of Mr. Richard Richardson, aged about twenty years, an apprentice to Mr. Thomas Sowray, draper, Pavement, who had been ill of the small-pox, and who, it was very strongly reported, had had his death considerably accelerated by taking Morison's Pills. To such a length were various rumours carried, that, on Saturday afternoon, it was determined to have an inquest held over the remains of the unfortunate young man; and Mr. John Wood, one of the coroners for this city, immediately issued his precept for summoning a jury.

Samuel Robson.—I am an apprentice to Mr. Sowray: deceased was also an apprentice there. He began to be ill on Monday the 16th of June. He told me on that day that he was ill; and, at his request, I felt at his breast, which was all full of rash. He also told Mr. Sowray that he was ill, who felt his breast at the same time that I did. I do not think that he took any medicine that night. On the following morning the rash had all gone in again. He took some pills that morning, of Mr. Sowray's, with whom he slept. I fetched a 5s. 6d. packet of pills on that day from Mr. Webb's, and Mr. Webb also came to see him. I can't say whether he was sent

for or not. I also fetched some ginger beer from Mr. Webb's, but never fetched any more pills. They were Morison's Pills. On the following Friday the rash again broke out. When Mr. Sowray came down stairs on that morning (Friday), he said, that "the deceased had broken out again, and that it was the small-pox." Mr. Webb had attended him during the week. After the spots had come out again on the Friday, Webb attended him every day, and sometimes two or three times a-day, I fetched Webb occasionally by Mr. Sowray's orders. Deceased told me he continued taking the pills; and, once, I saw him take some powder. He took it with ginger beer, or water and sugar, I can't say which. I believe he got the powder from Mr. Webb, and Mr. Sowray mixed it for him. When Mr. Sowray came into the shop after visiting the deceased, he always told us he was getting better; I thought from his appearance he was getting worse. When the eruption first came out, I did not see any on his face. When the pox came out again, there were a few on his face: they were very full on his breast,—clustered together; they appeared to die away in the afternoon. The pills he took on the Tuesday purged him very violently, as also did those he took afterwards. He was also very sick, and complained of great pain at his stomach. He never appeared to be delirious, but talked very little. He did not express any desire for a regular medical man, neither did I hear Mr. Sowray propose it to him. When he was first taken ill he did not complain to me of shivering or chillness. On the Friday, when the spots came out and died away, Mr. Webb said they would all die away in the same manner. Deceased continued to be very ill until Friday the 27th of June. He was not attended by any medical man, except Mr. Webb, until that morning, when Mr. James Allen, surgeon, came to see him, a little after eleven o'clock. Mr. Webb had visited the deceased that morning before Mr. Allen came. I fetched the deceased's mother the night before. When she arrived, Mr. Webb said he was better, and was coming round very nicely. Deceased appeared to be well up to Monday the 16th of June, and attended regularly in the shop until that day. He was never down stairs from that time except once, when he went as far as Mr.

Triffett's, which is the next door but one to our shop.

Mary Brittain, Mr. Geo. Robson, and Mr. Jacob Hugill corroborated the evidence of the first witness.

Mr. Joseph Spence, druggist, being a member of the Society of Friends, affirmed, I have examined the pills called Morison's pills, No. 1. In my opinion, they are composed of Cape aloe, gamboge, sulphate of potass, and gum guaiacum. I cannot state the proportions. I have examined the vegetable powder, but it is some time ago, and to the best of my recollection, it appeared to be composed of sugar, cream of tartar, and cinnamon. The pills now produced, No. 1, appear to be the same as those I have examined, and I should suppose are composed of the same ingredients. I have examined the pills, No. 2, and believe them to consist of about equal proportions of gamboge and aloes. Three pills of No. 1 weigh nearly seven grains; and three of No. 2 weigh nine grains.

Mrs. Elizabeth Whipp, mother of the deceased.—I was sent for by Mr. Sowray, and came on Thursday last; I found my son worse than I had anticipated, and mentioned my fears; Mr. Sowray told me, that Mr. Webb was attending him, and that he was doing very nicely. Mr. Webb also told me that he was getting better. Mr. Webb stayed with him until about twelve o'clock on that night, and I sat up with him all the night. Mr. Webb came again early in the morning. On Friday morning he took some roll and butter and coffee, of which he eat very greedily. Mr. Webb said that I had not taken proper care of him, and that the fever was very high. He also said that he would soon be better, as he had cured many cases of small-pox.

Mr. James Allen, surgeon.—I was called in to attend the deceased on Friday morning last, I attended him between eleven and twelve o'clock. Mr. Webb informed me that he had attended the deceased at his (deceased's) own request, and that it was a case of very severe small-pox. I then went into the room, and found him labouring under small-pox of a very bad sort. His eyes were very much sunk, his hands cold and livid, and the body covered with cold and clammy perspiration. I could not distinguish any pulse: the pox presented the appearance of perfect maturation. I told

Mrs. Whipp I considered her son in very great danger. Mr. Webb remarked, that the fever was very high : and I said, " if you can discover any pulse it is more than I can do." I directed some warm wine and water to be immediately given to him, by which deceased expressed himself very much relieved. I then gave him some cordial medicine, and saw him again about an hour and a half afterwards, when he was quite insensible and rapidly sinking, and died, I believe, within half an hour afterwards. When I first saw him I expressed my opinion that it was not possible to recover him. I examined the body on the following day (Saturday) in company with Dr. Wake, Dr. Belcombe, and Mr. Matterson. We found the stomach and bowels indicated considerable inflammatory action, the upper portion of the stomach approaching almost to mortification. This, in conjunction with the other morbid action, was quite sufficient to destroy life. The inflammation we found occasionally accompanies the small-pox, and other eruptive diseases. My opinion is decidedly that such treatment, as has been described by witnesses, was not only injudicious, but most calculated to render a mild and manageable case a highly dangerous one, by depressing the powers of life so frequently and constantly. Supposing the disease to have commenced on the Friday, when the eruption came out (and which I think is the day on which the disease ought to be taken to have commenced), then the patient dying on the following Friday was a period earlier than usual for patients to die of the small-pox. I am decidedly of opinion that the treatment he received was such as was calculated to accelerate his death.

Baldwin Wake, Esq., M.D.—I was present at the examination of the body on Saturday night, and found it covered with an eruption of the confluent small-pox. I observed the same appearances as those described by Mr. Allen ; and, having made similar examinations after death by small-pox, I observed, in the present instance, a greater degree of inflammatory action to have existed in the stomach and small intestines than I had ever witnessed before, which I conceive might have arisen from some severe irritant having been taken ; and finding that the diseased had taken very large doses of Morison's pills, which do contain gamboge, I have no hesitation in saying

that the appearances of the stomach were owing in a great measure to the highly improper exhibition of so violent a drastic purgative, which, by inducing extreme debility, must have converted a disease of a mild character into one of the malignant form which the body presented. It is my opinion that the number of pills described by the witnesses to have been taken by the diseased, in the short period of his illness, were sufficient to cause his death, independent of the disease under which he laboured.

William Matterson, Esq., surgeon, gave similar testimony ; and added, that he had been twenty years in practice, and had never known a case of small-pox become fatal when the patient had been vaccinated, and where proper treatment and attention had been given.

Henry Stephens Belcombe, Esq., M.D., also spoke in the same terms as the other medical gentlemen as to the appearances of the body after death, but would not go so far as to say that the quantity of pills which the diseased had taken would have the effect of producing the inflammation of the stomach. Gamboge, when taken in over doses, is a very deleterious medicine.

It being now ten o'clock, and there appearing no probability of the inquiry being concluded, the coroner adjourned the inquest until Tuesday evening, at seven o'clock.

Dr. Wake, on being further examined, deposed, that if the strongest man in York was to take thirty grains of gamboge per day, which he knew Morison's pills to contain, it would make him extremely ill, without his having any other disease. Each pill, as far as could be ascertained, contained about one grain of gamboge and one of aloes, so that taking thirty pills per day would be thirty grains of each drug. The proportion of the other ingredients in the pills was too small in quantity to neutralise the deleterious effects of the gamboge and aloes.

Mrs. Sarah Shepherd, of Gillygate, deposed to having heard Mrs. Whipp say she paid Mr. Webb 15s. for the pills.

The coroner then read over all the evidence, and told Mr. Webb that if he had any statement to make, he was ready to hear him, cautioning him, at the same time, that as it was impossible to anticipate what the verdict of the jury might be, though he would not

be on his oath, neither would he or the jury ask him any questions, yet he must take down what he said, and it might be produced against him in evidence, if future proceedings should be the result of the present inquiry.

Mr. Joseph Webb then stated that he wished to correct a statement which was contained in a letter to Mr. Robson, with respect to the time mentioned in it, which must be wrong, though it was written by himself. The letter states, that at six o'clock in the morning he thought he was better; which ought to have been, that, when he went at six o'clock in the morning, he found him altered for the worse. The letter was written under great excitement, and might contain expressions which he did not intend to convey. Mr. Webb then went into a minute detail of every circumstance that had occurred from the time of his being called up by his brother-in-law, Mr. Sowray, on Tuesday morning, the day following that on which the deceased was taken ill, to the time of his death. His statement occupied about three hours, and was patiently and attentively listened to by the jury; but as we have given the circumstances so fully, we do not consider it necessary to go through the whole of what he said. It was one o'clock in the morning before he had finished, at which time another adjournment took place.

The further Adjourned Proceedings.

At six o'clock on Wednesday evening, the jury again assembled.

Thomas Smith and John Render were brought forward by Mr. Webb; the former to prove that the deceased had told him he had the greatest confidence in Morison's Pills, and that he would take them in preference to any other medicine; and the other, that he had been cured of the small-pox by taking the pills. Mrs. Ann Rumfitt also deposed to the good effects she had received from taking the pills, both for the small-pox and other complaints.

The coroner then summed up: he said it was his duty now to address them in this important case, important not only to the public, but to the individuals concerned. He trusted they would dismiss from their minds every report or assertion they might have heard out of doors, and be guided solely by the evidence

which had been brought before them in their decision. The evidence had been heard at great length, and much time had been consumed in the inquiry, and all parties concerned had had an equal chance. They had listened to the evidence with great patience. It had been read over to them twice; but nevertheless, if they required it, he was ready to go over it again. He should abstain as far as possible from making any remark on the evidence, and confine himself to propounding the law as applicable to the case. There had been no evidence, neither had it been in any way suggested that there was a desire to impute any disposition to do injury to the deceased; consequently no question could arise as to that. That Mr. Webb had administered the pills to the deceased for the purpose of curing him, there could be no doubt; the question more immediately to be decided was, whether Mr. Webb had acted legally in administering medicine at all. The first question was, whether the deceased came to his death from taking Webb's medicine, which it was most important to decide, as on this must rest the foundation for their verdict; for if they were satisfied that the medicine had accelerated death, or caused the patient to die sooner than he otherwise would have done, which of course would be accelerating death, they must find their verdict accordingly; but if they were satisfied that he died from the effects of the disease, then they must say that he died by the visitation of God. The coroner next drew the attention of the jury to the law of the case, and quoted opinions on both sides of the question. The most important, however, and the one on which the most particular stress was laid, was that of Mr. Justice Bailey, in a case tried at Lancaster assizes in 1827. The prisoner was an old woman who had administered an emetic to a sailor, who had been discharged from the hospital at Liverpool, for the purpose of getting the mercury out of his bones, and the ingredients being of a deleterious nature, the man died from the effects of taking the powder, which was intended to cure him. The opinion of Mr. Justice Bailey was thus expressed:—"I take it to be quite clear, that if a person, not of medical education, in a case where professional aid might be obtained, undertakes to administer medicine which may have a dangerous effect, and thereby occasions

death, such person is guilty of manslaughter. He may have no guilty intention, or may have a good one; but he has no right to hazard the consequences in a case where medical assistance may be obtained. If he does so, it is at his peril." This the coroner thought the highest authority that could be brought to bear upon the case; and after again entreating them to dismiss from their minds all considerations but what were to be derived from the evidence, he left them to consider for themselves.

The Jury then retired; and, after an absence of an hour and a half, returned to have the evidence of the medical men again read, when they remained locked up for some time longer; after which they again came before the Coroner, and said that they were all agreed on their verdict except one. The Coroner said, if twelve of them were agreed he could take their verdict, but would prefer having it unanimous; and after hearing the evidence of Dr. Belcombe, they once more retired; but the refractory member declaring he would not give way, at very near 11 o'clock they came before the Coroner, and returned a verdict of "*Manslaughter*" against JOSEPH WEBB, at the same time stating it as their opinion that Mr. Webb administered the pills, not knowing that they contained any deleterious drug.

Mr. Webb immediately afterwards entered the room, attended by Mr. Leeman as his legal adviser, the latter of whom stated that Mr. Webb had come for the purpose of surrendering himself.

A commitment was accordingly made out and delivered to the constable; the Coroner also expressing a wish that, in consequence of the handsome manner in which Mr. Webb had surrendered, he should have every kindness shown to him by the constable.

Mr. Webb remained at his own house all night, and on Thursday morning was taken to the city jail.

CORONERS.

SIR,—Being aware that the subject of the attendance of medical men on coroners' inquests will not be overlooked by the Committee of which you are Chairman, I take leave to submit the following communication.

As the law now stands, a medical man who accidentally sees a wounded person before death is liable as a witness to give evidence before the coroner, and perhaps to be kept in attendance at some remote assize town for many days. For his attendance before the coroner he is seldom remunerated, unless the friends of the deceased are able and willing to pay him for his attendance; at a prolonged assize no payment would be a competent remuneration.

It is true that, if a surgeon has only been called to see the body after death, he may refuse to enter into a recognisance to give evidence at the assizes; but as it is impossible for any medical man to foresee the consequences of visiting a patient under any given circumstances, it is incumbent on the profession to obtain legislative interference for their protection.

It may not be inapplicable to mention, that at the special commission, held in Bristol in January 1832, three medical men were in constant attendance during the whole thirteen days, in compliance with a summons from the coroner. That officer very properly brought the subject prominently before the Judge (Mr. Justice Taunton), whose observations were exactly what might have been expected from so liberal and enlightened a character; but his power did not extend to any further interference in the matter.

Perhaps the most effectual method of obtaining the object in view, would be the introduction of a clause in the Bill now before a Committee of the House of Commons, to empower all coroners to issue a compulsory summons to the overseers of the poor, or other persons having the management of the poor-rates, to provide for the attendance of a surgeon upon every inquest, for the purpose of examining the body, or to give evidence, and to defray the expenses from the poor-rates.

There is no law by which any public officer is compellable to provide medical evidence, and the expense appears to be the real difficulty of the case.

I have the honour to remain, Sir,

Your very obedient servant,

WILLIAM HETLING.

HENRY WARBURTON, ESQ., M.P., Chairman
of the Committee on Medical Education,
House of Commons.

Clifton, Bristol, 13th June, 1834.

JOHN ST. JOHN LONG'S LOTION.—
 MORISON'S PILLS.

WE have this week to give a niche in our obituary to the celebrated John St. John Long. He died on Friday last, in consequence, says a Sunday paper, of a rupture of a blood-vessel, which occurred about two years ago; and it is but fair to add, continues our authority, that this was not one of the diseases he professed to cure. This is exceedingly consolatory to his afflicted patients, whose attachment to their master, and enthusiasm in support of his pretensions, paralleled and justified the bold effrontery with which he advanced them. He was a shrewd, clever man, and well versed in the weak points of human nature. A morning visit to his parlour at Harley-street afforded a valuable illustration of the powers of self-deception. There were assembled every morning a party of chronic invalids in the highest state of excitement; every one detailing, with pleasurable minuteness, the history and progress of his own ailments, and swallowing the nauseous recitals of others. After the first enquiries were over, the gentlemen stripped and rubbed in each other's presence, while a few straggling curious visitors were watching the miraculous effects. The great magician generally observed a discreet silence. Now and then he played Sir Oracle, but the master might repose under the zeal of his disciples. Soon after the untoward accidents of Miss Cashin and Mr. Lloyd he published a singular volume in abuse of medical practitioners, in which he explains his notions of diseases.

"The primary cause of disease," he said, "consists of a morbid fluid inherent

in the system, and incident to all of the human race." To the quantity of this morbid humour, more or less, he attributed the common origin of all diseases. And, in uniformity with the operations of nature, as exhibited in the earliest outbreak of this treacherous enemy in small-pox, his practice consisted in producing a copious discharge of the morbid humours, by the "attractive powers of his remedies acting as if a new gland had been added to the system." His embrocation had, he asserted, an attractive power over the disease, and produced no effect on a healthy part; and, of course, its power of healing the sore originally produced by it, when there was no more disease in the part, was duly asserted and authenticated. In one recorded case, a young boy suffered from a rotten tooth, which St. John Long very prudently advised should be extracted. The tender confiding mother objected, and appealed to the sovereign lotion. It was applied with faith, and the stump rejected its morbid humour, and all pain ceased. We have even heard faithful witnesses record instances of like extraordinary power of the lotion upon inanimate matter. In one case a handsome Turkey carpet was soiled by the upsetting of an ink bottle; the lotion was applied, and lo! the inky stain evaporated, and the pristine colours of the carpet revived untarnished!

This celebrated rubbing mixture consisted mainly of spirits of turpentine. It was oily and whitish;—at least, such was the lotion *after* the celebrated catastrophes. A large extent of surface was usually rubbed—the whole back or breast, or down the whole leg—and the friction was kept up for a considerable time.

St. John Long was dark complexioned, tall, and slender. His manners were plain if not vulgar. He seemed on terms of

perfect equality with his titled visitors, and bore with meekness the deference and adulation of his admirers.

We hope we shall be excused this slight sketch of the most eminent quack of modern date. Whether he has authoritatively disclosed his secrets we are not acquainted; but we are given to understand the consumptive portion of his mantle has fallen on Dr. Ramadge and Dr. Williams, of whom the former was a notorious admirer of the deceased.

Our readers will find, in another part of this Number, a strange account of a coroner's inquest upon a young man who was dosed with a meal, or meals, of Morison's Pills when suffering under small-pox—and died. We observed in a daily paper a report of *Purcell v. Stevens*, in which the plaintiff, a surgeon, got 500*l.* damages for a puff laudatory of Morison and libellous of the plaintiff, in the shape of a letter from a grateful mother whose child was cured by copious draughts of the same pills.

MEDICAL JURISPRUDENCE.

We find that, through inadvertence in a critique upon Mr. Chitty's extraordinary work on Medical Jurisprudence in our last number, we made an inaccurate statement, which, as it might be prejudicial to him, we hasten to correct. We stated, it appeared to us the author proposed to extend his work to five volumes as large as that already published. We find we were mistaken. It is stated to be his intention to compress the remaining four parts, into which he has subdivided his work, into a single volume; in which he proposes to comprise a practical view of Pathology, and Surgery and Therapeutics, a comprehensive view of Medical Jurisprudence, Police, and Evidence, the laws relating to Medical

Practitioners, and, lastly, a view of Medical Evidence. When we add to this the matter of the part already published,—Anatomy and Physiology, with a full account of the various functions,—we must be struck with the very expanded view Mr. Chitty has taken of his subject. All, in fact, that belongs to the human being is, he may say,

Nostris farrago libelli.

It is plain, from his own classification of contents, the author is sensible he has purposed far to exceed the limits of medical jurisprudence, as it is very accurately defined by Beck to be "that science which applies the principles and practice of the different branches of medicine to the elucidation of doubtful questions in courts of justice."

Reviewing the work before as an epitome by an unprofessional writer, of many popular treatises on distinct parts of medical science, we are filled with admiration of the happy manner in which the learned writer has brought the habits of his profession to bear upon a science so remote from his ordinary studies. His analysis of the works of others resembles those compact well-digested treatises, that make a lawyer's library, wherein there is little scope for originality, or pretence to it; but extreme industry, and caution, and precision are apparent. Our wishes, that Mr. Chitty's labours in the general collateral field he has chosen to traverse may be serviceable in extending the knowledge of medical science, exceed our hopes. We apprehend the generality of readers will prefer the less startling, more attractive pages of some original writer, whose work is not so multifarious. This desire to engross every thing in this elaborate treatise, is rather laughably exhibited in some passages we could cite. The whole doctrines of phrenology, ac-

according to De Ville, are stated at length ; and in the author's preface he points with satisfaction to this portion of his work, as useful to a judge, in order to counteract any attempt to prejudice a prisoner or witness by the appreciation of his countenance and supposed character upon the doctrines of phrenology or physiognomy. In another part we are minutely informed in a note, that " the period of separation of a husband and wife after parturition is usually a month, or after she has returned thanks for her deliverance, or, as commonly termed, been Churched. See the short service in Common Prayer, consisting of an exhortation, the 116th and 117th Psalms, the Lord's Prayer, and other appropriate thanksgiving!" This, it must be acknowledged, is an extravagant specimen, far exceeding any other we have met with: but instances of minor impertinencies are not a few; for example, the account of whistling, p. 95, and the descriptions of sighing and groaning, yawning and gaping, sucking, panting, straining, coughing, wheezing, sneezing, laughing,—the list is too formidable to go on with. In another place, we find the learned author intends to furnish a chapter on domestic medicine, with a list of recommended medicines, which country gentlemen should have in their houses, and directions how to renovate their medicine chest.

In pointing out these blemishes in our author's plan of monopoly, we are perfectly sensible of the great merit of his work as a clever compilation. The display of authorities is enormous, and sometimes partakes of the exuberance we have already remarked in the subjects he has handled.

Our author's summary of the leading works upon insanity is particularly good.

This subject, as a branch of mental philosophy, has been but very inade-

quately studied in the abstract by metaphysicians, who were wholly ignorant of the vital functions. It is impossible to sever judiciously the study of the phenomena of mind from a consideration of the corporeal instruments of thought. Much has been latterly done by physicians towards elucidating it. Amidst the mass, of which we must be for ever ignorant, we may hope there remains still more to be achieved.

Among the unprofessional authorities, we know of none of so great weight as Lord Erskine, in some of his celebrated speeches on criminal trials. We may perhaps introduce into our next number a long extract from one of these, which Mr. Chitty has had the good sense to select.

Since the preceding comments were in print, we have received a communication from Mr. Chitty, which he commences in these words:—"The general liberality of your reviews assures me you will take pleasure in withdrawing the sting of criticism, when you think it misplaced; and therefore I trouble you." He then replies to our strictures; and we shall have much pleasure in placing his statements before our readers in our next. In the mean time, we are bound to admit that it appears by Mr. Chitty's preface, to which he refers us, that our remark was unjust, when we supposed that he was not aware of the vitality of the embryo from the moment of impregnation. We offered the comment which was called for by the text, as we regretted that so able and eminent a lawyer had not emphatically exposed the absurdity of the law on animate and inanimate fœtuses. We also learn with astonishment, that Mr. Chitty alone compiled his laborious work,—a treatise decidedly the most comprehensive and most instructive, in our language, for non-medical readers.

**VACANCY IN THE PROFESSORSHIP
OF ANATOMY, TRINITY COLLEGE,
DUBLIN.**

WE regret to observe that the University of Dublin is about to lose the eminent services of Dr. Macartney, whose fame as a Professor of Anatomy and Physiology is well known in all civilised countries.

"Whereas it is provided by an Act of the 40th of George the Third, for establishing a complete School of Physic in Ireland, that the several Professorships in the School of Physic in Ireland shall be open for a new election at the end of every seventh year, unless the Board shall think fit to continue the same for another term of seven years, to all persons as well as the present Professor.

"Notice is hereby given, that the Board of Trinity College, Dublin, will proceed to an election of a Professor of Anatomy and Surgery, on Tuesday the 29th day of July next (which Professorship is about to be vacated), according to the 19th clause of said Act.

"The emoluments of the said Professorship consist of the fees paid by the Pupils who attend the Lectures given by the Professor of Anatomy and Surgery, viz.—(at present) Four Guineas for each Pupil; also a fee of Three Guineas from each Pupil who may attend the said Professor's Clinical Instruction in Sir Patrick Dun's Hospital; and also the fee of Thirty Shillings (late Irish currency), paid by the Students in Arts, in the University of Dublin, during their Senior Sophister year.

"By the said Act it is directed that all persons, intending to offer themselves as Candidates, shall send in their names, the place of their education, the Universities in which they have taken their degrees, and the places where they have practised, to the Registrar of Trinity College, and to the Registrar of the King and Queen's College of Physicians in Ireland.

"By Direction of the Board,

"ROBERT PHIPPS, Registrar, Trinity Coll.

"G. A. KENNEDY, M.D., Registrar, King and Queen's College of Physicians in Ireland."

Dublin Papers, July 4 and 5.

**PROVINCIAL MEDICAL AND SURGICAL
ASSOCIATION.**

It is, no doubt, in the recollection of many of our readers, that an association under the above name was formed, under the most promising auspices, at the Worcester Infirmary, in July, 1832; and that its first anniversary was triumphantly held at the Bristol Infirmary, on the 19th of July, 1833. At each of these meetings some of the most distinguished cultivators of medical science, resident in the English provinces, were present; and as the result of the labours in which they have been employed, the society have already published two volumes of Transactions, singularly rich in practical information. We have neither time nor space to enter into any detail of the extended objects which engage the attention of this flourishing society; but we have much pleasure in announcing that the second anniversary meeting, which will rival in interest and importance either of those which have preceded it, is fixed to be held at Birmingham, on Friday, the 18th inst., and that Dr. Johnstone will preside on the occasion. Some idea of the importance of the meeting may be formed from the following extracts, which we have made from the circulars sent to each member, announcing the anniversary:—"The general meeting of the members will take place at the theatre of the Philosophical Institution, in Cannon-street, at half-past twelve o'clock; at which meeting a report of the proceedings of the past year will be made by the council. Dr. Conolly, of Warwick, will also deliver an oration, in which he will take a retrospective view of the principal medical occurrences of the past year. Reports on the different branches of medical science, fixed upon at the last anniversary meeting, will be given in by the respective members who were appointed for that purpose. Communications will also be read from the members for foreign correspondence, and the general business of the Association will be transacted. The lecturers of the school of medicine have been so kind as to arrange that the museum of anatomy, and of natural history, shall be open during the day; and any member of the Association will, on application, be admitted to inspect the same." We observe, also, that

the members of the Association, amidst all their zeal for science, do not neglect to pay due attention to bodily comforts, for after meeting they intend to dine together at Dee's Royal hotel, where, doubtless, every delicacy of the season will be produced for them.

Foreign Hospital Reports.

L' HÔPITAL MILITAIRE DE VERSAILLES.

Wound of the Chest, with Lesion of the Pericardium.—Cure.

FAVIER, carabinier to 2nd regiment, twenty-three years of age, of robust constitution, received on the 15th of February, 1834, a cut from a sabre in the chest, about two inches in length, between the seventh and eighth ribs of the right side, about two inches from the sternum. About eight in the evening, he was brought to the hospital much inebriated, so that no particulars could be ascertained as to his exact position when he received the wound.

The surgeon on duty examined the wound, found that its direction was from right to left, but did not probe it to any considerable extent, for fear of producing hæmorrhage. The surrounding parts became emphysematous; sixty leeches were applied, and the part, after their application, covered by a poultice. Bleeding was deferred until the next morning, in consequence of intoxication.

16th. Pulse small and retracted; laborious respiration; hæmoptysis; countenance extremely anxious; excessive thirst; skin hot and dry; complained of acute pain in the præcordial and epigastric regions; emphysema not diminished. Scarification of the painful parts; diet, gum water. The scarification produced slight alleviations; in the course of the day his countenance became flushed, eyes glassy, and pulse increased in frequency; cephalalgia supervened, and he complained of excruciating pain in the cavity of the chest. Twelve ounces of blood were taken from the arm, and he passed a tranquil night.

17th. Wound remains the same; great sensibility of the epigastrium. Ten leeches were applied, from which, for a short time, he found relief, but towards the evening dyspnoea increased; pulse became more frequent; pro-

fuse perspiration ensued; features became contracted; great anxiety of countenance; no rest.

18th and 19th. Symptoms remained much the same. Bloodletting and scarifications were again had recourse to; and on the 19th all the symptoms appeared alleviated.

20th. Symptoms of irritation have again returned; the neighbouring parts of the wound are continually emphysematous. Towards noon the patient was attacked with violent cough, and difficulty of expectoration, which was tinged with blood; much dyspnoea; excruciating pain at the lower part of the chest: pulse hard and accelerated. Ten ounces of blood were again extracted from the arm.

21st. Always at noon the symptoms become worse. Has been slightly delirious. Mustard poultices to the feet. Sulphate of quinine to be taken two hours before the usual period of the increase of symptoms.

24th. All the symptoms are alleviated, the patient has become more rational, and feels stronger.—Medicines to be continued.

25th. Has slight difficulty in respiration; cannot lie on the left side, which emits a dull sound on percussion, particularly inferiorly. This side is more prominent than the right, nevertheless there are no symptoms indicative of effusion. A large blister was applied on the affected side, and this relieved the difficulty of respiration. No sooner had he obtained this relief than he was attacked with violent pain in the shoulder, the accession of pain always increased towards evening. It was combated by blisters and increased doses of quinine; and on the 22nd of April he was sufficiently well to leave the hospital.

British Hospital Reports.

ST. THOMAS'S HOSPITAL.

Efficacy of Iodine on Secondary Syphilis.

(Continued from p. 735.)

CASE IV.—George Leighton, a butcher, aged 34, of sanguineous temperament, and good constitution. States that he has twice been the subject of venereal chancres; the first that he suffered from is about six years ago, the ulcers healed after taking a few doses of mercury, without the least salivation being produced; no secondary symptoms supervened, and at the expiration of two years, he again contracted the same affection. At this time,

before the healing of the sores, he was profusely salivated, which appeared to destroy the venereal virus, and, as he thought, to have entirely eradicated it from his system; for not until six months ago, four years from the last attack, he experienced any thing like secondary syphilis; at this time a copper-coloured eruption made its appearance, and pains of the limbs supervened. His medical attendant again prescribed mercury for him, which controlled, to a certain extent, the eruption, but the pains of his limbs increased, became so excessive, that he could get no rest. On the 19th of June he came into Edward's Ward under Dr. Williams; at this time the pain continued severe; there were lumps on the periosteum covering the tibiae, which from the least pressure by the finger caused excruciating agony. Eight grains of the hydriodate of potass were prescribed; in the course of five days the pains had nearly disappeared, the thickening of the periosteum gradually subsided. He is now perfectly well, with the exception of a slight eruption in various parts of the body, this has not at present been inclined to subside under the influence of the iodine. He states positively that he has not had the venereal disease for the last four years, moreover that he has been married for the last three.

CASE V.—Edward Burke, an Irish labourer, aged 36, who states twice in his life he has been unfortunate enough to have contracted this disease; the first time was about eight years ago, and the latter about a twelvemonth since; at both periods he was profusely salivated, and always obliged to continue his work during the continuance of the mercury. Has several times suffered from pains in his limbs, but never so severely as two weeks previous to his admission. He came under Dr. Williams into Edward's Ward on the 19th of June; there was then great thickening of the tibial periosteum, pains so excessive that he could scarcely move about, in which state he had been for a fortnight. The hydriodate of potass, in the same proportion as in the other cases, was prescribed; the pains soon ceased, and the nodes are fast disappearing.

CASE VI.—Joseph Lawrence, of short stature, and scrofulous diathesis, a tailor, 18 years of age, who was first affected by the disease a twelvemonth since, came into the hospital last November, with ulceration of the bones of the nose, throat, and pharynx, and with such excessive pains in the limbs, that he was unable to move. Dr. Williams prescribed for him the hydriodate of potass, which in the course of a week so much relieved him, that, at the expiration of that time, he could walk about the ward. The ulceration of the nose and pharynx varied sometimes for the better, and others for the worse, and has not, apparently, been the least alleviated by this medicine. He still remains in the hospital for this latter disease, but the pains have not returned.

The hydriodate, after being discontinued for three months, within the last week has again been prescribed, and certainly with slight beneficial improvement.

Many other cases to illustrate the efficacy of this medicine on this particular stage of the disease, we could subjoin from the above hospital, but most of them so nearly resemble those we have already observed, and the control of this medicament over certain stages of this disease being so satisfactory, that a further number of cases we fear would be tedious. Nevertheless, as a still further proof of the effects of this medicine, we cannot do better than subjoin a case illustrated by Dr. Williams before the College of Physicians, and which, in fact, appears to be the chief cause of his persevering research.

CASE VII.—Isaac Chitton was admitted into St. Thomas's Hospital 17th January, 1831, with large periosteal nodes on each tibia; his sufferings were most severe, and his health was much impaired. The first medicines that were prescribed for him were mercurial, and he was salivated, but his pains returned as soon as his mouth healed. A decoction of smilax aspera was next tried, but without success. On the 7th of April, therefore, the decoction of sarsaparilla was substituted, and which was taken till the 2nd of June, a period of nearly eight weeks, but still there was no alleviation of his sufferings; on the contrary, the first phalanges of the second and third fingers of one hand became thickened, and in a short time the inflammation terminated in necrosis, so that one finger was obliged to be amputated; and this untoward event occurred in spite of the application of leeches, and a variety of local treatment, as also of minute doses of the pil. hydrargyri, and of colchicum, and even of the nux vomica, which was tried when the other medicines failed in producing any good effect.

The parts having healed, experiments became necessary to save the other finger, which seemed to be rapidly running into a similar state of necrosis. On the 2nd of July, therefore, and not until nearly six months after his admission into the hospital, five grains of the potassæ hydriodatis, out of camphor mixture, were ordered three times a day; and this quantity was, during some part of the treatment, increased to ten grains. The results were most happy; his pains were relieved, the nodes subsided, and his finger was saved. This patient subsequently laboured under iritis, ulcerated throat, affection of the nose, and also of the skin, as also of the ligaments and synovial membrane of the joints, and was consequently under my care or observation for at least twelve months afterwards, but had no return of the periostitis.

CASE VIII.—The treatment of this case had scarcely terminated, when the coachman of a member of parliament was admitted into St. Thomas's Hospital, with an exactly similar

state of the tibiae, and of the phalanges of the fingers. This man had been for many months under a treatment by mercury and sarsaparilla, and was so reduced by constant suffering that his family thought his death inevitable. Eight grains of the hydriodate of potass were directed to be taken by this person three times a day; and in two months he was discharged cured.

A vast number of cases might be cited from the wards of Drs. Elliotson and Roots, which have been controlled by this medicine; but these gentlemen have not only been satisfied with its internal effect, but have had the iodine ointment rubbed on the affected surfaces, and I think I may say in every instance attended with the most beneficial result.

Rupia has also been checked by the internal use of this medicine; but in almost every instance, owing probably to some peculiar state of constitution, this disease has remained stationary while under its influence; and the cases that we here subjoin, in proof of its efficiency on this state of the disease, it will be right to observe, the patients who were submitted to its use had no periosteal inflammation.

The first was a man named Lucrane, admitted under Mr. Tyrrel's observation. He was attacked with rupia, which extended all over his body; the ulcerated patches increased in size; his constitution became so much debilitated, that no hope of his recovery was entertained. Sarsaparilla and almost every remedy that could be suggested, were had recourse to, but without success. At last, Mr. Tyrrel prescribed for him the *mistura potassæ hydriodatis* three times a day:

Iodine gr. ss.

Potass. Hydriodat. 3ss.

Aquæ Puræ ʒ viij.

Fiat *mistura*, cujus sumat cochlearia iij *ampla* ter die.

After a short perseverance in this treatment, the ulcers became healthy, his constitution improved, and, after continuing it for some time, he became well enough to leave the hospital. It is now since the commencement of 1832 that he was attacked; the disease has not since returned, and he remains in a tolerable state of health.

Another similar case to the above, after suffering for a long time with ulcerations about the face, nose, and various parts of the body, was put under the influence of this medicine by Mr. Travers; the parts kindly healed, and he became quite well. Some months afterwards, the disease again made its appearance, for which he has been since admitted into the hospital. He is now taking the *mistura potassæ hydriod.* three times a day, and the disease is rapidly disappearing.

From the preceding observations, this medicine appears to have a specific control over the distressing pains resulting from this disease, and appears to check the osseous deposition, which is the commencement of the hard periosteal node, and in many cases causes its entire

disparition. Another most happy result from this medicine is (and which puts it beyond comparison with the powers of mercury) that we have not those distressing effects arising from enlargements of the salivary glands, which so often passed into a state of suppuration, debilitated so much the constitution, that death frequently was the result. There yet remains much to be done; the good effects of this medicine, in particular stages of this disease, are any thing but satisfactory, for instance, there are, at this present time, cases in the hospital in which the syphilitic eruption has disappeared under its influence, and others in which it has remained stationary; again there is a case of caries of the bones of the nose, which has been greatly mitigated by its use, and another which we have recorded above, in which no beneficial effects were observed. However, by comparing these two cases together, one suffering excruciating agony from pains and periosteal inflammation, whilst the other merely had slight roughness of tibial periosteum, its different effects are not surprising; and further, when it be recollected during the time the former suffered so severely from the pains in his limbs, the disease of the nose remained in a state of torpidity. Thus, then, when disease is set up in two different tissues of the body, we observe the virulent effect of one checking the progress of the other, so we must expect with medicine in controlling the most severe form of the disease, that all its powerful agents are absorbed by the one, which, until entirely eradicated, are unable even to mitigate the other. In Case VI. it will be observed that the medicine was left off after one form of the disease had been checked, and when continued three months afterwards, its effects over the other form became manifested.

Thus, then, we can observe the happy effects of medicine over such a specific and deadly poison, combated in one form by mercury, another by sarsaparilla, and in the third by hydriodate of potass, the latter medicine subduing the last stage, which is increased, if not often produced, by the former.

WESTMINSTER HOSPITAL.

Salutary Effects of the Application of Caustic Potass to a Scirrhus Breast.

—Holingsworth, æt. 40, of emaciated appearance (the result of her disease), came into the hospital last October with scirrhus of the right breast, under which she has been labouring during the last several years. Since her admission into the hospital, Sir Anthony Carlisle has resorted to all those remedies generally used in such cases; but the sufferings of the patient were not in the least alleviated, and her symptoms assumed a very aggravated and pressing character. Her appearance gradually became exceedingly miserable, and her situation on the whole very precarious. An operation was not had recourse

to, as the disease was too extensive, and consequently the chances of recovery very small. A short time ago, she was removed from the care of Sir Anthony Carlisle to that of Mr. White, who ordered the diseased parts to be frequently touched with the caustic potass. Mr. White is convinced that though the disease in question cannot be entirely cured, its symptoms may be considerably alleviated, and the sufferings of the patient much lessened. His anticipations have been in a great measure realised. The disease has put on a milder and less severe character, and the poor woman has greatly improved in flesh. Her nights are not as formerly sleepless, and her health appears considerably renovated. It is not improbable that she may survive many years under the disease.

Erysipelas of the Leg.

Mary Poole, æt. 65, was admitted on the 30th June with erysipelas of the right leg. According to her own account, her limb has been swelled during the last three months, and, about a week previous to her admission, assumed the erysipelatous character, accompanied with a sensation of burning heat in the parts. She attributed the erysipelas to a severe wetting which she recently encountered. She was ordered to take

R. Submur. hydrarg. gr. v.
Ext. colcyn. gr. x.
Fiant pil. ii. Capiat stat.
R. Confect. aromatic. 3 j.
Carbon. ammon. 3 ij.
Tinct. cinchonæ, 3 ij.
Decoct. cinch. 5 vij.
Capiat 3 ij. 4tis horis.

The results of this treatment have been most favourable. The tumefaction of the limb has subsided, the pain has disappeared, and the leg is almost restored to its pristine state of health.

ROYAL COLLEGE OF SURGEONS.

NAMES of Candidates who received Diplomas during the month of June 1834.

T. M. Lambert	Hull.
J. Hirst	Boynhill, Yorkshire.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE XCVIII., DELIVERED APRIL 30, 1833.

GENTLEMEN,—I have now to describe to you the operation for strangulated femoral hernia; and you will find that it is not always performed in one way, different surgeons having different modes of proceeding, according to their view of the parts chiefly concerned in forming the stricture, and of the safest place for the incision, with reference to the epigastric artery and spermatic vessels; for the round ligament in the female ought not to have much influence on the question, a wound of it being a thing of little importance. At the school where I was brought up, the surgeons usually began the operation by making an incision, which commenced about an inch above the crural ring, or pubic portion of Poupart's ligament, and extended obliquely downwards and outwards over the centre of the swelling. This plan answered very well where the intention was to divide Gimbernat's ligament near the pubes, in order to free the protruded parts from strangulation in the crural ring itself, and to be able to reduce them. In other words, you can in this manner very safely and conveniently get at the side of the crural ring, which I have specified as formed by Gimbernat's ligament. This is the mode of proceeding I have commonly adopted myself, on the principle that the seat of strangulation was mostly at the crural ring, and indeed I have always found that a proper division of Gimbernat's ligament has enabled me, as well as others whom I have seen operate, to reduce the viscera without difficulty. This first incision is likely to divide the external pubic artery, and it exposes the superficial fascia, which is here generally thicker than what lies over an inguinal hernia, though, in thin persons, and recent cases, it may be so delicate as to escape notice. After the division of the skin and superficial fascia, you

come to the tubular sheath of the femoral vessels, or *fascia propria*, as it is named by Sir Astley Cooper. Your next object, gentlemen, is to lay open the fascia propria, first lifting up a piece of it with the forceps, and then making a small opening in it with the edge of the knife directed horizontally. A director is then to be introduced into the aperture so made, and the fascia propria divided upwards and downwards to the neck and fundus of the sac. After having laid open the fascia propria, you may meet with a quantity of fat, which, in consequence of the long pressure of trusses, sometimes presents a thickened dense feel, and assumes very much the appearance of indurated omentum, so as to cause an erroneous suspicion of the hernial sac having been already divided, followed by pernicious efforts to push back the parts into the abdomen. This is a subject, on which you will find most useful practical information delivered in Key's edition of Sir Astley Cooper's work on Hernia. Here is the book, and a plate exhibiting an unopened sac pushed back into the abdomen with the strangulated bowel in it. The hernial sac having been exposed is now to be cautiously opened, in which step of the operation first nip up a small portion of the fundus of the sac, and feel that no portion of the contents of the hernia is directly within it. Then take hold of it with the forceps, and make a small opening in it with the edge of the knife directed horizontally, and kept close to the extremity of the forceps. On this being done, a certain quantity of clear or turbid serum mostly gushes out, but not invariably. The director is now to be introduced, and the sac laid open upwards and downwards to the crural sheath and fundus of the sac itself.

Having proceeded thus far, gentlemen, it sometimes happens that you may easily return the contents of the hernia without the further use of the knife; but, unless this be practicable without any squeezing and bruising of the parts, the stricture ought to be cut. In this very important stage of the operation I have generally been accustomed to divide Gimbernat's ligament, and with it the neck of the hernial sac, and the contiguous part of the fascia transversalis. A director is introduced along the inner side of the protruded viscera into the

crural ring, with the groove turned towards the pubes. Then, with a narrow probe-pointed bistoury, or with Sir Astley Cooper's hernial bistoury, which has but a small cutting edge, and none at all towards the point, so as to occasion less risk of wounding the bowel, you are to cut the base or deep expanded part of Gimbernat's ligament in the direction inwards, or inwards and upwards. In this part of the operation you find the bowel continually exposed to injury, on account of the small space in which you have to act, and I recommend you, therefore, not only to use this kind of bistoury (suggested by Sir Astley Cooper) for the division of the stricture, but to be particular in keeping the intestine out of the way of the instrument with your own left fore-finger, or with the hand of an assistant. I ought to have mentioned to you, gentlemen, that sometimes when you make the incision in the skin, you find the hernia concealed by dense fat and enlarged diseased glands, and you are not to be perplexed by the circumstance, provided you are clear and certain respecting the existence of hernia. I remember being sent for to a poor woman in St. Giles's, last Twelfth-night, for a strangulated femoral hernia, when, as the symptoms were urgent, and I had not much time to spare on account of a private engagement, I proceeded to the operation directly after the taxis had failed. Now, on making the incision through the integuments, I came to such a mass of diseased fat and glands, that I was a little staggered, and led to consider for a minute or two whether I might not have been in too great a hurry to operate, and mistaken a case of enlarged glands for a hernia. But a little reflection convinced me that the patient's symptoms could not depend upon the latter cause; and, on dissecting more deeply, I came to a small hernial tumour. The patient recovered, as I think most patients do, in whose cases the operation is not deferred till too much inflammation and other mischief have had time to take place.

When the bowel has been strangulated beyond a certain time, it becomes dark coloured, and though not actually gangrenous at the period of the operation, it will sometimes give way afterwards. This happened in a case, where I operated rather too late on the sister of the celebrated harlequin, Bologna. She was a dancer, a profession which, you know, is particularly exposed to the risk of herniæ. After the operation, her sufferings ceased; she had several motions, and her pulse came down to 80; but, all on a sudden, forty-eight hours after the operation, she was seized with excruciating agony in the abdomen, faintings, quick faltering pulse, and cold sweats, with which symptoms she soon died, and, on opening her, it was found that a small point of the ileum had given way, that the contents of the bowel had become effused, and that a rapidly fatal inflammation of the peritoneum had been the consequence.

Gentlemen, if you begin the operation, and open the hernial sac in the manner explained

to you, it would not be safe to cut the crural ring upwards in a male subject, because you would wound the spermatic cord. In a female, however, in whom we find that this hernia is most common, I do not know that the round ligament need frighten you from cutting in this direction, if you had any reason for selecting it. You could not cut upwards and outwards, because you would injure the epigastric artery, and you could not turn the edge of your knife precisely outwards, or in the direction away from the pubes, because you would wound the femoral vein. The safest plan, therefore, seems to me to be generally that of making the requisite division of the crural ring by cutting inwards, or inwards and a little upwards.

The only case in which the division of the deeper part of the stricture, in the direction inwards, would be attended with danger, is that in which the obturator artery arises from the epigastric, high up, and, in its way into the pelvis, descends round the inner margin of the crural ring. This position of the obturator artery, however, in relation to the neck of the sac and the crural ring, is computed not to occur more frequently than once in about eighty cases of femoral hernia. The way of operating, gentlemen, which I have been describing to you, has not the sanction of some surgeons, for whom I entertain the highest respect, and though it is the method which I have adopted, and found answer, let me not induce you to suppose that I do not see reasons for sometimes following other plans. Where the hernia is larger than it commonly is, I would make the incision in the skin in the way preferred by Sir Astley Cooper and Baron Dupuytren; that is to say, an incision in the shape of the letter T reversed. For this purpose, you may lift up, with the aid of your assistant, a longitudinal fold of the skin over the tumour, divide it transversely, and then make another cut from Poupart's ligament downward, so as to join the transverse one. The flaps or angles are then to be dissected up, by which means greater room is obtained for future proceedings, than in the method of operating already explained to you. With respect to other modes of dividing the stricture, I may inform you, that Sir Astley Cooper cuts the anterior part of the crural canal by carrying the knife as far as the front margin of the crural arch, in the direction upwards and inwards. When this is not sufficient, he next cuts the thin posterior border of Poupart's ligament in the same direction.

There ought, indeed, to be some variety in the method of operating, according to the circumstances of each individual case; and the valuable investigations of the eminent surgeon, whom I have mentioned, tend to prove that the seat of strangulation in femoral hernia is not always in the same place, but may be either in the crural sheath, where the stricture is occasioned by the semilunar edge of the fascia lata; or it may be at the posterior edge of the crural

arch; or, lastly, at the mouth of the hernial sac, in the fascia which covers it.

Having laid open the hernial sac, Sir Astley Cooper introduces his probe-pointed bistoury, which does not cut near the point, into the crural sheath, at the anterior part of the sac, and divides with it the sheath as far as the front edge of the crural arch. This cut, which does not exceed half an inch, he finds sufficient for the reduction of small herniæ. But if the bowel cannot now be returned by gentle pressure, he passes in his finger about half an inch higher, and divides the posterior edge of the crural arch and fascia transversalis immediately next to it. As these two incisions are made from within the sac, they will of course remove any stricture formed by the sac itself. The direction of an incision for the division of the stricture, which he deems most eligible, is upwards, with a slight obliquity towards the umbilicus.

Baron Dupuytren, in operating on femoral hernia, cuts the same parts as Sir Astley Cooper, but uses a curved probe-pointed bistoury, which cuts with its convexity; it is introduced into the crural sheath flat on the left forefinger, and its edge is then turned upwards and outwards, and the upper extremity of the falciform process divided as far as the front margin of the crural arch. Hesselbach also regards an incision through the front side of the crural canal safer than one through Gimbernat's ligament. These distinguished operators, though directing the knife towards the spermatic cord, do no injury to it, because they take care not to cut beyond the anterior margin of Poupart's ligament. Dupuytren also avoids the epigastric artery by taking care to make a very limited cut.

Here, gentlemen, is a preparation exhibiting a femoral hernia, in which the operation has been performed, and the intestine reduced. In this instance, you see that the surgeon has cut the neck of the sac. In the next specimen, the strangulation is also in the neck of the sac. The intestine is in a mortified state, as evinced by its colour. The distended inflamed portion of it within the abdomen is the upper part of the canal. The protrusion, you may observe, is merely a small fold of the bowel.

Gentlemen, I next proceed to speak of *congenital inguinal hernia*, the great peculiarity of which is, that the protruded viscera lie in the tunica vaginalis, which serves as the hernial sac. The bowel or omentum is therefore in contact with the testicle.

The congenital inguinal hernia arises in the following manner. In the foetus, the testes are situated immediately below the kidneys, on the forepart of the psoas muscles, with their anterior and lateral surfaces covered by reflected peritoneum, and their posterior surfaces connected to the psoas muscles by means of cellular substance. About a month or six weeks before birth, but sometimes subsequently to this event, the testes descend through the abdominal ring into the scrotum, where there

is a production of the peritoneum already formed for their reception, and afterwards constituting the tunica vaginalis. The testes in their descent, gentlemen, do not fall loose into the tunica vaginalis, but carry with them the peritoneum immediately adherent to them.

Soon after the testes have got into the scrotum, the upper part of the tunica vaginalis is closed, by which change all communication between the cavity of that membrane and the belly is shut. Sometimes, however, this closure is delayed, and then, if any of the bowels insinuate themselves into the passage, they become of course, as long as they continue unreduced, an impediment to its further obliteration; and the case is a congenital inguinal hernia.

The congenital inguinal hernia, therefore, differs from all common herniæ in having no hernial sac produced by a protrusion of the peritoneum with the bowels themselves.

No doubt, gentlemen, one of the most frequent predisposing causes of congenital hernia is the occasional delay in the descent of the testicle, which circumstance has the effect of retarding the closure of the passage between the belly and the scrotum.

Gentlemen,—You should understand, that the disease is not generally produced by the insinuation of the bowel into the tunica vaginalis at the same time as the testicle itself. Before birth, the small intestines are but little distended, and, in the absence of respiration, they can suffer no compression from the diaphragm and abdominal muscles. Hence, notwithstanding the expression *congenital*, the disease is hardly ever noticed in infants directly they are born, but makes its first appearance afterwards.

One accidental circumstance, however, may really make the hernia strictly congenital, namely,—the intestine or omentum may become adherent to the testicle previously to its leaving the abdomen, and consequently descend with it into the scrotum before birth.

The formation of such adhesions between the bowels and testicle before birth, may also sometimes prevent or retard the descent of the latter organ.

Frequently you will be consulted for cases of congenital herniæ, where the testicle has not yet descended through the ring.

The congenital inguinal hernia must always necessarily be external, or oblique, because the neck of the tunica vaginalis invariably corresponds to the point, at which the spermatic cord passes under the border of the transversalis muscle. Also, as the tunica vaginalis enters the inguinal canal beyond the point at which the spermatic cord crosses the epigastric artery, it must have this artery on the internal side of the ring.

In young children, you will find, that the congenital hernia more frequently contains intestine than omentum, because in them the latter part is very short.

The impossibility of feeling the testicle, while the bowels are down, is the most im-

portant criterion between this hernia and a common bubonocoele, where you can always feel the testicle at the lower and back part of the swelling. Then a suspicion of the nature of the case may be entertained, if the hernia has existed from early childhood; not that infants may not be occasionally the subjects of common bubonocoeles.

Gentlemen,—I may next observe, that the viscera, included in a congenital hernia, but more especially the omentum, are frequently adherent to the testicle; a complication attended with serious inconvenience, unless removed, as it prohibits the reduction of the protruded parts, and the use of a truss. The bowel and omentum may also adhere to the sac, and sometimes to the sac and testes at the same time.

A congenital inguinal hernia is to be treated on the same general principles which apply to other herniæ. If the bowels admit of reduction, the patient be young, and a proper truss constantly worn, the communication between the abdomen and scrotum will frequently become obliterated, and a radical cure be the result. The chances of this desirable event diminish, however, as the individual grows older, and, after the adult age, a truss can hardly ever be safely dispensed with.

Unfortunately, you cannot always apply a truss, as must be obvious, when it so happens, that a piece of intestine or omentum is in the sac, while the testicle is in the groin, or even within the abdomen, for, in the first case, it would press upon and inflame the testicle, and, in the second, prevent its descent.

However, if the patient should be beyond the age, when any chance of the descent of the testicle exists, I would recommend you to reduce the hernia, and apply a truss.

In young subjects, in whom no congenital hernia exists, but one or both testicles have not yet passed the ring, their descent should be watched, and as soon as they are low enough, a truss should be worn, constructed so as not to make any hurtful pressure on them.

The congenital hernia is remarkable for the thinness of its sac, as manifested in this preparation, a fact dictating caution in the first steps of the operation. The sac is indeed frequently not thicker than the natural peritoneum.

This hernia, gentlemen, is also well known to be particularly often strangulated at the inner opening of the ring, or by a contraction of the neck of the sac within the inguinal canal.

The congenital hernia has another peculiarity, which is, that it sometimes becomes strangulated by constrictions in the body of the sac. In the preparation 726 the stricture is pushed down quite to the testicle.

As the epigastric artery is always on the inner side of the neck of the sac, the division of the stricture may be safely made, either directly upwards, or upwards and outwards.

I need hardly remind you, gentlemen, of the care that should be taken not to handle,

wound, or in any manner injure the testicle in the operation.

I must not conclude the account of congenital inguinal hernia, without mentioning one peculiar case that is sometimes met with, consisting of a protrusion of the viscera, together with a peritoneal hernial sac, into the cavity of the tunica vaginalis. It is formed after the recent obliteration of the communication between the abdomen and the tunica vaginalis. Were you not aware of the possibility of such a case, you might be considerably perplexed on meeting with it. Here is a preparation of a double kind of hernia,—first, a congenital one, with omentum in it, and then you see another hernial sac pushed down into the tunica vaginalis.

Hernia of the Cæcum and Colon, gentlemen, are attended with particularities well deserving your notice.

Scrotal herniæ of the right side, formed by the cæcum, the appendix vermiformis, and commencement of the colon, draw after them into the scrotum that portion of the great bag of the peritoneum by which those viscera are naturally fixed in the right ileo-lumbar region; and, on opening the sac, you will find the cæcum and colon connected to this part of the peritoneum, just as they were in the abdomen previously to the displacement. The same kind of natural adhesion of the large intestines to the hernial sac may also take place in a scrotal hernia of the left side, when the protrusion consists of that part of the colon, which is naturally fixed in the left ileo-lumbar region by duplicatures of the peritoneum.

Another peculiarity of these herniæ arises from the fact that the cæcum and beginning of the colon are partly situated out of the peritoneum; hence they can only be partially surrounded by a hernial sac, a portion of their external side being in immediate contact with the adjacent cellular membrane. In such a case, were the surgeon to cut too much towards the outside of the tumour, he would find the cæcum and colon immediately under the cremaster and infundibular process of the fascia transversalis.

From what has been stated, gentlemen, you will readily understand the cause of another peculiarity of herniæ of the cæcum and fixed portion of the colon, namely, the impossibility of their reduction. The appendix vermiformis may be returned, but the cæcum itself cannot be reduced, unless the sac itself admit of being replaced.

The circumstances which I have explained, must make it a matter of importance to discriminate a hernia of the cæcum and beginning of the colon from others. Now, *such a case can only form gradually*; the displacement of the cæcum and colon, fixed as they are in their natural situation, must be a slow process. Herniæ of sudden formation, therefore, cannot be of this kind. The tumour will also generally be of large size, of long standing, and of an irregular knobby shape.

In this species of hernia, as well as in all others of large size, the symptoms of strangulation are seldom violent, on account of the width of the opening through which the protrusion takes place. You must in such cases be cautious not to mistake the colic and irritation, to which the viscera in the tumour are liable, for the symptoms of strangulation. When a large old scrotal hernia is really strangulated, the evacuations from the bowels are always totally suppressed, the swelling is painful, and the patient is affected with vomiting, eructations, and fever. On the contrary, in the colic from irritation, resembling strangulation, the discharge of air and feces from the rectum is never entirely suppressed; and the evacuations are increased when mild purgatives and clysters are given. If nausea and tendency to vomiting occur, it is at long intervals, there is not much fever, and the swelling, though tense and bulky, is not painful on being handled. Under such circumstances, mild saline purgatives, clysters, and cold applications, may frequently be employed with success, and you should not be in haste to perform an operation.

But, if a large hernia of the cæcum were to be truly strangulated, you should remember, before you begin the operation, that the bowels will not admit of being completely returned, on account of their particular and natural adhesions to the sac; and that in this, as well as in all scrotal herniæ of large size, the neck of the hernial sac is not the seat of strangulation. Perhaps the best plan would be merely to expose the abdominal ring, and make a division of it, upwards and outwards, without opening the hernial sac at all, and then try to reduce the viscera as far as practicable.

Gentlemen, the *Exomphalos*, or *Umbilical Hernia*, is a protrusion of the viscera through the navel, or in the neighbouring part of the linea alba. The first case, whether met with in the infant, or adult, has a *circular neck*, at the circumference of which, the tendinous margin of the umbilical ring can be felt. Whatever may be the size of the tumour, its body always retains nearly a spherical shape; nor can any wrinkle of the skin, nor anything at all resembling the cicatrix of the navel, be seen upon the convexity or the sides of the swelling.

On the contrary, in a hernia of the linea alba, the *neck of the swelling* is of an *oval shape*, like the fissure through which the protrusion has taken place; and, if the hernia be very near the navel, the *umbilical cicatrix may be seen on one of the sides of the swelling*; a sure proof that the viscera do not protrude through the umbilicus itself.

In a true exomphalos, the tumour in a thin person is free and pendulous; in a fat subject, broad at its base, less prominent, and hence spherical. The protruded parts will naturally tend downwards, so that the opening into the abdomen is from the upper part and not from the middle of the swelling, as exhibited in the specimen before us.

The umbilical hernia is not only furnished with a true peritoneal sac, as you see in the preparation, No. 721, but with a superficial investment of condensed cellular substance. The coverings of this hernia, however, are frequently very thin, and, in old cases, portions of the sac are sometimes absorbed. In the preparation 723 the most prominent part of the sac is exceedingly thin, nearly absorbed, and closely connected with the integuments: nay, the viscera may be adherent to the integuments, and strangulated in the opening in the sac, through which they have protruded, and which has been occasioned by its partial absorption.

Gentlemen, an umbilical rupture in an adult rarely contains intestine unaccompanied by omentum; and I may also tell you, that it happens with much greater frequency in women than men; a fact explicable by the consideration that pregnancy has more influence than any other cause in bringing on the complaint. Dropsical and corpulent subjects, however, of both sexes are liable to the disease.

Herniæ of the Linea Alba, or *Ventral Herniæ*, of which one example is before us, an epiplocele, are much slower in their progress than true cases of exomphalos. On account of their small size, gentlemen, they are frequently unobserved, especially in corpulent subjects, or when situated on one side of the ensiform cartilage. However, they bring on complaints of the stomach, and habitual colics, and are more liable to simple obstruction, than strangulation with inflammation and tendency to gangrene. But when this state unfortunately does occur, the symptoms are more intense, and the accession of mortification more rapid, than in any other species of hernia. Even when merely the omentum is strangulated, the symptoms are particularly violent, a circumstance ascribed to the proximity of the stomach.

When practicable the exomphalos and ventral herniæ should be reduced, and a truss worn. You will find in Hey's surgery the description of an excellent truss for umbilical hernia. In young subjects the pressure of a truss will often radically cure the disease; and the plan is much more commendable than that of reducing the viscera, and then extirpating the integuments and sac with a ligature.

When, in adult subjects, an operation is unavoidable, the sac should be laid open with the greatest caution, and the umbilical ring divided either directly upwards or downwards. When the hernia is very large, but not attended with gangrene, you should be content with cutting the umbilicus, without opening the sac at all, or as little of it as possible.

The division of the stricture in ventral hernia may also be made upwards or downwards, due regard being paid to the epigastric artery which crosses the linea semilunaris.

In *Cystocele*, or *Hernia of the Bladder*, the protrusion is most frequently through the abdominal ring; and generally in male subjects who have been repeatedly afflicted with

retention of urine. Cystocele has been noticed, however, in children, from the irritation of stone, and even in women from the effects of dropsy and pregnancy.

Gentlemen, you well know that only the fundus and a part of the posterior surface of the bladder, down to the insertions of the ureters, are covered by peritoneum. Now, as it is usually the anterior and lateral part of the bladder, which first passes through the ring into the scrotum, the peritoneum will not protrude at the same time, and the displaced part of the bladder will not be covered by a hernial sac; but, as more of it descends, its fundus at length passes into the scrotum, drawing after it the peritoneum naturally attached to it. Thus the bladder first protrudes, and a hernial sac follows afterwards, into which a portion of the omentum, or intestine may glide. Here the bladder is invariably excluded from the other hernia, and situated at its posterior and inner side.

Sometimes the case is reversed, and the cystocele is the consequence of an ordinary hernia.

The symptoms of cystocele are a fluctuation in the tumour, the swelling becomes large and tense when the patient holds his water, and diminishes when the urine is discharged. If the scrotum be compressed, an inclination to make water is experienced. Sometimes the muscular coat of the bladder being paralytic, the patient cannot expel the urine from the swelling, unless he raise and compress the scrotum; indeed, as the bladder is always drawn to one side, the patient invariably has some difficulty in making water, and is sometimes afflicted with a total retention.

The disease has been mistaken for hydrocele, though the marks of difference are great. Thus, the tumour produced by the bladder always extends into the ring, the testicle is plainly perceptible below the swelling, and the tumour diminishes when the patient voids his urine.

Cystocele may occur also under the crural arch, in the perinæum, or the vagina.

The reduction of a cystocele is soon rendered totally impossible by adhesions; and all that can be done is to apply a suspensory bandage. If a total retention of urine were to attend it, caused by the displaced condition of the organ, and not to admit of a catheter being passed, the swelling should be punctured. If a calculus were to form in the protruded bladder, an incision might be practised for its extraction.

Gentlemen, this is all the information which I can offer on the subject of hernia in these lectures. Some rare forms of the disease, like herniæ at the foramen ovale, or ischiatic notch, in the vagina or perinæum, or through the diaphragm, you will probably never meet with; though I would still advise you to remember them, and be prepared for them. You are more likely, I think, to meet with cases in which the bowels within the abdomen become strangulated by accidents, displacements, bands of adhesion, or various other causes.

NON-EXISTENCE OF VAGINA, REMEDIED BY AN OPERATION.

BY JOHN C. WARREN, M.D.,

Professor of Anatomy and Surgery in Harvard University, Boston.

A YOUNG woman, twenty-three years old, well constituted, applied to me for a natural malformation of the organs of generation. On examining, I found the os externum wanting, and, so far as could be judged, there was no vagina. The aperture of the urethra was well formed; the clitoris and nymphæ appeared as usual. The breasts and all the other external parts were natural; but no uterus could be discovered on a careful examination by the rectum, either by Dr. Channing, Dr. Hayward, or myself. The patient had never experienced any unusual enlargement of the abdomen.

Believing it possible that the uterus might exist, although not sufficiently developed to be discoverable by the rectum, I determined to comply with the patient's wish and attempt the formation of an artificial passage: for this purpose she entered the Massachusetts General Hospital in January last.

The patient being placed on her back on the edge of a bed, feet each in a chair, I attempted to pass a probe in behind the urethra, but found this impracticable, there being no aperture or excavation. The forefinger of the left hand was introduced into the rectum, and a small probe-pointed bistoury employed to make an aperture in front of the rectum as near as might be in the situation of the fossa navicularis. This was accomplished, but I was disappointed in finding no cavity behind or within this aperture. It was necessary, therefore, to proceed with the same instrument, the convexity being towards the rectum, to dissect from behind forwards. In this way an opening was made sufficient to admit the point of the finger. The dissection being carefully continued in the same manner, a passage was formed about three inches long, and wide enough to admit the finger.

The bleeding was considerable; this was arrested by the introduction of a tent. Subsequently to the operation she had much fever, pain and tension of the abdomen, and suppression of urine. The symptoms gradually disappeared.

The wound was carefully dressed by the introduction of a tent daily. The suppuration was considerable ; after it had subsided the tent was removed, and the passage exhibited no disposition to close.

On examining subsequently to the cicatrisation of the wound, something like labia of the os uteri was discovered.

After her recovery she had some appearance like a catamenial discharge. She then left the hospital. Four weeks afterwards she was seen by Dr. Hayward ; he found the aperture and cavity open, and she had had a sanguineous discharge resembling the catamenia ; and he thought he could distinguish something like an uterus.—*American Journal of the Medical Sciences.*

DR. TYTLER'S PROOFS OF THE REAL DISCOVERER OF GALVANISM.

We copy the following statements from the work of Dr. Tytler, published in India in 1819, entitled "A Concise Narrative of Facts, connected with the Disease which occurred in the District of Jessore during the Months of Aug. and Sept., 1817 ; together with Observations upon its Symptoms, Causes, and Treatment. By Robert Tytler, M.D., M.A.S., Assistant-Surgeon, Civil Station, Zillah Jessore." In a former number of this Journal we inserted the author's history of contagious diseases, and we feel that no one can peruse it without awarding to him the merit of great research, profound erudition, strong reasoning powers, and very extensive observation on the cholera of Jessore in 1817. In the history to which we allude, Dr. Tytler has, in our opinion, satisfactorily and incontrovertibly proved that deteriorated grain was the cause of pestilence in many ages and countries. We have also shown, by a history of the epidemic diseases of Ireland, from the earliest period of the history of that country to the present time, published in the present volume of this Journal, that famine and pestilence have borne the relation of cause and effect in that part of the United Kingdom.

Dr. Tytler is entitled to the thanks of all civilised governments and nations for his exposition of the deleterious influence of bad rice in causing Asiatic cholera abroad and at home ; and he has accumulated such a mass of evidence on this point as ought to lead to

the prohibition of the sale of bad rice. We refer to his pamphlet for this evidence ; and shall now introduce his facts with respect to the real discoverer of galvanism. They appear to us to be conclusive ; but we leave our readers to form their own opinions.

"It is not unfrequently noticed that traces of scientific discovery, the reputation of which is claimed by natives of other countries, are, in the first instance, to be found in the labours of our own countrymen, who, although the merit of originality attaches to them, receive but little, if any, of that fame which is liberally bestowed on more fortunate and later observers. As a proof of one instance of this description, I give the following extract from the 2nd vol. of the Medical Essays, published in Edinburgh so far back as the year 1734.

"Dr. Alexander Steuart, Physician to the Queen of England, having cut off the head of a frog, observed, that upon thrusting a blunt probe into the medulla spinalis the muscles of the body were brought into convulsive contraction : and that the same happened to the muscles of the head when the probe was thrust into the brain ; from which he concludes the brain and nerves to contribute to muscular motion, and that to a very high degree."—*Phil. Trans.* No. 424.

"This passage contains indisputable testimony, that the leading fact upon which the discovery of galvanism is founded was first made by a Briton. I am not aware of this circumstance having been mentioned in any publication that details the manner in which this extraordinary agent was accidentally detected by Galvani. The discovery, as is well known, is universally admitted to have originated with him, or rather his wife. But, admitting that he was unacquainted with the important fact, which had been previously ascertained by Dr. Steuart, surely this gentleman deserves, at least, equal merit, although his pretensions, probably from being unknown, never appear to have been acknowledged.

"As I understand that this communication has attracted some attention from those who feel an interest in scientific pursuits, and having procured the volumes of the Philosophical Transactions, which contain the account of Dr. Steuart's experiments, it may probably prove acceptable to my readers, to afford a more enlarged detail of what appears, to myself at least, an indubitable fact, viz., that the

phenomena, at present known under the name of galvanism, were distinctly described to the Royal Society of London, and printed in their Transactions several years prior to the birth of Galvani, who was not born till the year 1737. The experiments of Dr. Steuart were performed, according to his own testimony, for the purpose of proving the existence of the nervous fluid. But, at the commencement of his process, he detected galvanism, and mistaking the phenomena excited by this stimulus for effects produced by the presence of a fluid existing within the nerves, otherwise named animal spirits, he there stopped, contenting himself with having afforded, as he imagined, a complete demonstration of his theory, which was deemed of so much consequence in the animal economy, and practice of physic. Thus biassed by a preconceived hypothesis, he rested, as it were, upon the threshold of nature's portal, and, unfortunately, refrained from prosecuting this interesting subject of inquiry, and confirming by its means those mighty results to which his discovery was calculated to lead, and, in the hands of others, has subsequently produced.

"His first experiment is detailed in the Philosophical Transactions for the years 1731 and 1732, and is as follows:—

" ' I suspended a frog by the fore legs in a frame, leaving the inferior parts loose; then the head being cut off with a pair of scissors, I made a slight push perpendicularly downwards, upon the uppermost extremity of the medulla spinalis, in the upper vertebra, with the button end of the probe, filed flat and smooth for that purpose, by which all the inferior parts were instantaneously brought into the fullest and strongest contraction; and this I repeated several times on the same frog with equal success; intermitting a few seconds of time between the pushes, which, if repeated too quick, made the contractions much slighter.' "

"Now, on reading this account, can we doubt that these convulsions were entirely owing to the misnamed galvanic fluid? the merit of whose discovery becomes in consequence due to this ingenious and learned gentleman. To avoid all cause of irritation, the blunt end of the probe, it appears, was flattened, and therefore to no other cause excepting galvanism can this singular result with propriety be ascribed. In this instance, a very high degree of merit attaches to Dr.

Steuart for this blunting of the probe, or, in other words, applying a broad surface of metal to the nervous substance was not the mere effect of chance, but the result of a process of reasoning, which, however erroneous, is nevertheless extremely ingenious. Thus in the Croonian Lectures, on Muscular Motion, printed in the same Transactions, for the year 1737-8, he observes,—'The extremity of the probe applied in this experiment being flat, cannot produce this effect by irritation, but by compression; and (reader, mark the ingenuity of the inference) the compression of the pliable extremities of tubes, full of any fluid, must depress or propel the contained fluid towards the lower or opposite extremities, with an increased degree of velocity.' But setting aside altogether the cause of nervous sensation, it is evident that the effects here produced entirely arose from galvanic stimulus, excited by metallic application. In the second experiment, which is not less decisive, the same results, and by the same means, were obtained.

" ' With the same flat button end of the probe, I pushed slightly towards the brain in the head, upon that end of the medulla oblongata, appearing in the occipital hole of the skull, upon which the eyes were convulsed. This also I repeated several times, on the same head, with the same effects.' These were followed by an experiment of a different description, made in order to ascertain the comparative elasticity of arteries, veins, and nerves, and, finding that the latter do not contract upon being removed from the body, he draws these conclusions. The two first experiments show, that the brain and nerves contribute to muscular motion, and that to a very high degree.

" ' The third experiment makes it as plain, that what they contribute in muscular motion, cannot arise from, or be owing to, elasticity, which they have not.

" ' What remains, therefore, but to conclude, that the action of the nerves in muscular motion, is owing to the fluid they contain, by whatever name we may choose to call it.' "

"To establish Dr. Steuart as the discoverer of galvanic effects, produced upon the nerves by the application of a metal, it only remains for us to be convinced, that the motions, thus excited in the limbs of the animal, were

actually those which we are accustomed to describe under that denomination. But on this can a doubt reasonably be entertained? And hence it follows that the discovery of this agent, as I have already mentioned, was not only fully detailed, but commented upon to the Royal Society by a native of Great Britain, even previous to the birth of the Italian philosopher, from whom it so undeservedly derives its appellation.

“The work of Mr. Wilkinson, which is the most elaborate upon this subject, commences with the following remark:—

“‘The first printed notice which is to be found of the phenomena since called galvanic, is in a work by Sultzer, published in 1767,’ &c. Now, sir, it is most assuredly remarkable, that, with the Philosophical Transactions in our hands, such an assertion should not only be made, but universally admitted, and moreover that it should have continued without contradiction, or even an attempt offered to vindicate to Dr. Steuart the fame to which he is so justly entitled. Our astonishment at this circumstance, however great, is considerably increased, when we find the fact upon record, that his experiments were not performed in the humble laboratory of an obscure chemist, but, as is attested, in the presence of the Royal Society, who returned their thanks upon the occasion.

“‘At a meeting of the Council of the Royal Society, Nov. 12, 1739. These letters on muscular motion, by Alexander Steuart, M.D., &c., having been, according to the will of the Lady Sadlier, communicated beforehand to me, and approved, and afterwards read at several meetings of this Society, for which he received their thanks, I do direct the same to be printed. HANS SLOANE, P. R. S.’

“The incident, which is said to have attracted the attention of Galvani to the powerful natural agent since known by his name, is not unlike the experiment of Dr. Steuart, for the contractions were excited also in the limbs of a frog, and by the same means, viz. the application of a single metal. The accidental presence of an electrifying machine, and no anterior process of reasoning, induced him to conceive that such convulsion might possess some connexion with electricity, an idea that has led to all the discoveries that have since ensued. In the case of Dr. Steuart, circum-

stances were not so favourable, yet he unequivocally succeeded in demonstrating the operation of the same wonderful agent, which was destined to be re-discovered (if the expression be correct) on the continent, and thence being transmitted to England, under a novel and foreign appellation, has immortalised, by the decomposition of the alkalies, the name of Davy, and affected an important revolution in the whole system of chemical science. The inattention of scientific men to the experiments of Dr. Steuart, particularly since the period in which the same phenomena were noticed by Galvani, is strangely unaccountable. Yet are the prominent features of the discovery as distinctly exhibited in them as in those performed by him or Volta; after perusing the facts published by the Royal Society, ought we for an instant to suspend our judgment in declaring whether to the Briton or Italian the honour of this important discovery belongs. It is certainly much to be regretted, that an unmerited appellation, now sanctioned by custom, should have crept into general use, by which our ingenious countryman, having never possessed the reputation of this discovery, is deprived of the fame which he justly deserves, yet may we trust that, in future accounts of Galvani's *glorious* career, this error will be corrected, and some amends made by succeeding authors for the injustice of their predecessors.”

REPORT OF MIDWIFERY CASES,

BY FLEETWOOD CHURCHILL, M.D.

Licentiate of the King's and Queen's College of Physicians, Ireland, Physician to the Wellesley Institution for Females, Lecturer on Midwifery, with Diseases of Women and Children in the Medico-Chirurgical School, Digges-street, Dublin.

CASE I.—(Which occurred to me in Edinburgh.)—Mrs. Simpson, æt. 35, mother of several children, sent for me January 3, 1831. I found the pains strong and recurring quickly. The bag of waters protruded through the vaginal orifice. Having ruptured this, I ascertained a head presentation in the first position. The child was soon expelled, without diminution of the uterine tumour. As there was some hæmorrhage, I made an examination, ruptured the second membranes during a pain, and, finding the feet at the

upper outlet, brought them down, and delivered the child. Still the uterus preserved nearly the same size, and, on the rupture of the third membranous pouch, the head of the other child presented, and was speedily expelled, followed by the body and lower extremities. All the children lived for three months; the second labour was a girl, the others boys. As there was a tendency to hæmorrhage, I extracted the placenta (a double and a single one) as soon as possible. The whole labour occupied but two hours. Some flooding took place during the day, which was arrested by a dose of laudanum, prescribed for her by my friend Dr. John Moir, at that time one of Dr. Hamilton's annual pupils. From this time nothing untoward interrupted her recovery.

CASE II.—Triplets.—Mrs. Kane, æt. 35, healthy, having had two children after natural labours, on the 5th of May, 1834, engaged me to attend her in her approaching confinement, and consulted me upon her enormous size, and the anasarous state of the lower extremities. Upon examination I found the abdomen very large and tense, with very evident fluctuation upon the slightest touch in any part. The skin did not pit on pressure. On applying the stethoscope, I heard a loud pulsation of the foetal heart. This convinced me that the distension was intra-uterine, and I regret that I deferred to a second visit a more minute investigation. The limbs were greatly distended, and pitted on pressure. She stated herself to be in the eighth month of pregnancy. I recommended rest, with the horizontal posture, and prescribed some aperient medicine. The next morning I was sent for and found labour commencing. The cutting pains were frequent, the os uteri dilated, and the bag of the waters protruding. Whilst endeavouring to ascertain the presentation, the membranes gave way, and the liquor amnii was discharged. I could then feel the head of the child in the first position. After a short interval the pains recurring expelled the child, a healthy girl, about the usual size of twins. The size of the abdomen was scarcely diminished, and in about ten minutes another pain occurred. The membranous bag protruded, and I ruptured it. The head presented in the fourth position of Nægelè, *i. e.*, with the anterior fontanelle directed

towards the right acetabulum. As the head descended, the rotation described by that author commenced, but ere it could be accomplished, the head of the child, owing to its small size, was expelled, with the face looking (upwards and rather to the right side). The chin was not extricated from under the pubic arch until after the vertex and posterior part of the occiput had swept through the perineum. The body was delivered immediately. The infant was a male, about the size of the former, and living. The poor woman to my astonishment complained now "of something kicking" in the abdomen, and, upon placing my hand there, I felt plainly enough the motions of another infant. The pain coming on I ruptured the membranes; the head presenting in the first position, the child was speedily expelled, and proved to be a girl. Scarcely any draining had as yet occurred, and the binder previously applied having been tightened, she was allowed to rest a little. She was a good deal exhausted, though not alarmingly so.

Her pulse was a little weaker than natural. The whole delivery from the rupture of the first membranes had not occupied more than an hour and a half. I now examined the three cords, and having found the one which yielded the most on a slight attempt at traction, I extracted the placenta by pulling gently and at intervals. It proved to be the one to which the two cords were attached. The other was delivered in the same manner immediately after.

CASE III.—Twins—Breech and Footling Case.—Mrs. B—, a healthy woman, the mother of three children, sent for me at midnight, having been taken in labour two hours before. She had calculated upon having yet a month to go before her accouchement. The waters were discharged an hour previous to my visit. I found the pelvis filled by a round soft tumour, which I recognised to be the breech, the genital organs were towards the left side, and the right tuber-ischii presented. The usual half turn was made, and the body and feet expelled. I extracted the head with the face in the hollow of the sacrum. The child was alive. On applying my hand to the abdomen, I found the uterine tumour still large, and a vaginal examination discovered another bag of water, which I ruptured on

the occurrence of the next pain. A single knee (the right) presented, the foot and leg being folded back; with a little assistance the body descended, and I extricated the other foot, and with some difficulty and delay the head. After a short time respiration was established. Both children were girls, and one died the next day; the other is thriving well. The placenta, a double one, was expelled in about five minutes without hæmorrhage. The woman recovered in the usual time. Three points of considerable importance present themselves to our notice in the preceding cases. The rupture of the membranes after the birth of the first child, the management of the second and third children, and the delivery of the placenta. Generally speaking within about half an hour after the birth of the first child, slight pains recur, and they appear to me to point out the period for rupturing the second membranes, as no good can arise from waiting, but much mischief and inconvenience may be the result. The parts are already dilated by the passage of the child, and the only change in them produced by waiting would be a partial return to their natural calibre. On the other hand, cases are met with where the uterus remains inert for several hours if left to itself, and in these surely rupturing the membranes, after the lapse of half an hour, might render artificial labour unnecessary. As to the second point there are two opposite opinions maintained by authors as quoted by Denman; those who advise the instant delivery of the second child by the feet, and those who would leave it entirely to nature. Denman himself advises not to interfere until after four hours, and then, if there are no pains, to deliver by turning. Hamilton advises the same after one hour. Dr. John Clarke agrees with Denman, provided it be not a cross-birth. Burns coincides with Hamilton. But I need not multiply authorities. It is evident and agreed upon that, if the second presentation be preternatural or the labour complex, instant delivery must be attempted. But if not, it appears to me much wiser to leave the labour to nature, after rupturing the membranes, unless the uterus should remain inactive for a very long time. The binder, which should, if possible, be applied after the birth of the first child, will probably be a valuable aid in

producing uterine contractions. There can be no necessity for introducing the hand, whether the head, breech, or feet present, if there be no complication. The only precautions to be adopted with regard to the placenta, appear to be to ascertain, by gentle traction of each cord, which placenta (supposing there to be two) is the more completely detached, and to extract that first. It is also well to remove both as soon as possible, in order to avoid the danger of flooding. In the cases recited, I pulled each cord gently, and finding one give more than the other, I extracted by that, and the second placenta followed immediately.

CASE IV.—*Unavoidable Hæmorrhage—Prolapse of Funis.*—March 15th, 1834. I was sent for to visit Mrs. —, a dispensary patient, who had been during the last fortnight attacked with frequent flooding without apparent cause. She stated herself to have gone her full time. The waters had not been discharged, and the grinding pains were pretty severe, with some draining. On making an examination, I found the external parts somewhat rigid, and the pelvis not very large; the os uteri dilated to the size of half a crown; and, upon passing my finger through it, I distinctly felt the edge of the placenta extending to the os uteri, but *not further*, and situated at the left side and rather posteriorly. The head of the child presented; and within the membranes I could feel a loop of the cord. From the state of the os uteri and passages, I did not think that turning afforded any greater chance of saving the child than natural labour. I therefore ruptured the membrane, which increased the uterine contraction. The hæmorrhage ceased instantly. Unfortunately, the funis prolapsed, and, as the child could not pass rapidly through the pelvis, the circulation was arrested, and the child died. The placenta was expelled without hæmorrhage. The cord was found inserted near the lower edge, and the opening in the membrane close to the placenta. The woman did well.

This case affords a beautiful example of a transition from one variety of hæmorrhage to another. Strictly speaking, it was a case of unavoidable hæmorrhage, i. e. the separation of the after-birth, causing the flooding, was occasioned by the dilatation of the cervix; and

yet the remedy for accidental hæmorrhage was applicable, and succeeded in this case. The moment the head of the child came in contact with the placenta, the flooding ceased. I felt some difficulty in deciding whether or not to turn the child, as the probability of prolapse of the funis was very great. But, as the state of the passages gave very little hope of being able to extract the child footling speedily, so as to save its life, and as the operation of turning might endanger the mother, I decided to leave the operation to nature. After much reflection I think I did right, though I lament that so little can be done in funis presentations. Every plan I have yet seen appears either insufficient or very objectionable.

CASE V.—Spontaneous Evolution.—I was sent for on Friday, July 27, 1832, to visit Mrs. Fitzsimmons, æt. 36, who had been seized with labour pains three hours before. She has had eleven children, several of them cross-births. She supposed herself in the eighth month of pregnancy. She is a healthy woman, with a well-formed pelvis. On examination I found the right arm protruded through the external parts and quite livid. At this time the labour pains had somewhat diminished in violence; but, upon passing a finger into the vagina, I found the finger of the child so jammed in the pelvis, that any attempt at turning was quite out of the question. In this dilemma I fortunately obtained the assistance of my friend Dr. Gordon. Before he had finished his examination of the presentation, strong uterine contraction came on. The shoulder of the child was forced under the arch of the pubis; then appeared successively the right side of the thorax, abdomen, and pelvis. The bending of the hip-joint allowed the body of the child to free itself from the vagina, and then the knees and feet were expelled without assistance, the child remaining suspended by its head from the pelvis. As the pains continued, I had no difficulty in extracting the head. The placenta was expelled without hæmorrhage. The foetus was dead, but not putrid: it appeared fully the size of an eight months' child. The woman recovered, and has since had two children.

This case, extracted from my note-book, was taken down before I had read any explanation of the evolution, except Denman's,

to which it is diametrically opposed. It would be presumption to question Denman's accuracy as regards his own cases; we can only look on them as remarkable variations from the ordinary process. I have since read all the other explanations, and derived much pleasure from the very intelligent and accurate observations of Dr. Douglass. Drs. Gooch and Burns coincide with Dr. Douglass. Dr. Kelly, of Swords, is opposed to the view taken by Dr. Douglass, and endeavours to support the opinion of Denman, with an important alteration, viz.—that the retraction of the arm takes place during the *relaxation* of the uterus, instead of during the *contractions*, as Denman supposed. He relates no cases, so that I know not whether his observations are the result of theory or practice. He certainly does not appear to do justice to the simple yet clear description of Dr. Douglass.

A case is related in the last Number of the Edinburgh Medical and Surgical Journal, by Dr. Malcolm, as illustrative of the process of evolution, in which, however, he anticipated the completion of the natural process by bringing down the feet. It appears to me, that the mechanism of evolution is sufficiently simple. The head, descending, catches upon the rim of the pelvis, and, by the violent uterine contraction, is turned to one side, whilst the arm, becoming free, falls down into the vagina. Now, if the pelvis be large, or the child unusually small, the continued powerful uterine contractions force down the parts next to that already in the pelvis, viz., the thorax and abdomen:—for the head, we have seen, is fixed. This process continuing, the body, hips, and lower extremities of the child are expelled successively, leaving the head to the last, as in a footling case. I do not deny that perhaps too much value may have been attributed to this process, for we cannot be certain of its taking place; but, on the other hand, there appears to me to be a mistake on the part of its opponents, who strenuously advise never to neglect turning in hope of a spontaneous evolution. Of course not; I know of no such proposition; the alternative is not *turning*, but *evisceration*.

Neither in Denman's, Douglass's, Malcolm's, or my own case, was turning practicable, or it would have been attempted. But surely, when this is out of the question, and the side of the

thorax seems descending after the shoulder, it is better, if the state of the woman permit, to wait a little than to perform a troublesome, and possibly hazardous operation, and which is still a resource available if evolution do not take place.

Since writing the preceding, a case resembling the above has been related by Mr. Thurman, in the *Lancet*.

**MEDICAL ADDRESS TO MR. WAR-
BURTON.**

At a Special Meeting of the Medical and Surgical Society of this town, held on 11th June, 1834, the following Address was unanimously approved of, and has since been forwarded to Mr. Warburton, Chairman of the Parliamentary Committee of Inquiry into the present state of the Medical Profession.

Address of the Medical and Surgical Society of Newcastle-upon-Tyne and its vicinity, to Henry Warburton, M P., Chairman, and to the Members of the Committee appointed by Parliament, to inquire into the present state of the Medical Profession, and to report thereon.

"Gentlemen,—In common with the majority of our professional brethren, throughout the United Kingdom, we are deeply impressed with the zeal and impartiality which you have shown, during the present inquiry; and we deem it to be a duty, which we owe at once to society, our profession, and your honourable committee, to lay before you a sketch of the state of the medical profession in this extensive and populous district, and, subsequently, to submit with much respect, for your consideration, some suggestions which have occurred to us, as desirable in connection with anticipated reforms, when such shall be under the deliberation of the legislature. It may be satisfactory to inform you, that the Medical and Surgical Society consists of about sixty members, and includes physicians and surgeons exclusively.

"Physicians.

"In Newcastle and Gateshead there are eleven physicians, who practise without dispensing medicine. All, with one exception, (a respected and accomplished graduate of

Groningen) are Edinburgh graduates. Two of the number are licentiates of the College of Physicians in London; although originally possessing the same degree with the rest, the licentiates are alone cognizable as physicians in a court of justice in England, or indeed legally licensed to practise medicine; and they only are protected by law in case of professional libel, as was lately ruled by Chief Justice Denman, in the case of Collins v. Carnegie. Hence, those, not licentiates, practise by sufferance only, and although educated in a medical school of such celebrity as Edinburgh, yet are denied privileges granted to graduates of Oxford and Cambridge, in neither of which places is there a perfect school of medicine; thus exhibiting the absurd anomalies, which arise from corporate abuse and nationality. Physicians have no legal claim for professional remuneration.

"Surgeon Apothecaries, or General Practitioners.

"There are about sixty surgeon apothecaries, or general practitioners. They all dispense medicines. A large majority are not licentiate apothecaries. The greater number are members of the College of Surgeons in London. Many are licentiates of the College of Surgeons in Edinburgh; and a few have diplomas from Glasgow. Very few of the last classes are licentiates of Apothecaries' Hall; and, therefore, although well qualified, are liable to considerable difficulty, from the absence of legal claim to remuneration. London diplomatists (not licentiates) share this disadvantage with them, but to a less degree; and all are liable to a penalty being inflicted (if not licentiates) by Apothecaries' Hall. Remuneration is almost exclusively derived from medicines dispensed, so that a large proportion (not licentiates) are at the mercy of their patients, according to the decision of Chief Justice Best, in Common Pleas, Steed v. Henley. This mode of remuneration is peculiarly disagreeable to the respectable practitioner, as either not being sufficient, or subjecting him to suspicion of sinister views in the mind of his patient. Neither should the impossibility be overlooked, that some (to be hoped few) less scrupulous, may dispense unnecessary or injurious quantities of medicine.

"Apothecaries.

"A few apothecaries, not surgeons, practise indiscriminately.

"Druggists.

"Many druggists in this town dispense medicines, and some to a very considerable degree prescribe, and even visit patients. There is too much reason to fear, that many of this class, including their assistants, are very incompetent, in the important branches of materia medica and pharmacy. It frequently occurs, that various other branches of trade, as groceries, &c., are carried on in the same shop, thus increasing the possibility of errors, and adulteration. Such establishments sell patent medicines and nostrums largely.

"Quacks, and Quack Medicines.

"This, like most other towns, is frequently visited by quacks, in the characters of dentist, oculist, aurist, surgeon and physician. The traces of their ruinous and irresponsible treatment too often meet our view, in the suffering victims of their cupidity and ignorance. There are three establishments devoted to the sale of quack medicines, which are, unfortunately, largely patronised by the credulous and ignorant. There are four or five repositories for patent medicines, all of which sources of mischief, it is painful to say, derive but too much support from the public press, which fosters the evil on account of advertisements. It is to be lamented that the duty on patent medicines, about forty-five thousand pounds sterling, annually, should weigh with our enlightened legislature for a moment, in the toleration of so sadly increasing an evil.

"Coroners and Medical Evidence.

"Here one of our coroners is always a medical man; an usage, for the ends of justice, which should prevail more generally throughout the country. Medical men here, as in other places, feel the disadvantage of possessing no legal claim for remuneration, when required to give evidence as to the causes of death, &c.

"Hospital, Dispensaries, &c.

"Newcastle possesses an excellent infirmary, containing 152 beds; to which four physicians, four attending, and two consulting

surgeons, are attached. In this institution a clinical surgical lecture is delivered twice a week. Newcastle has also a well supported dispensary, to which six physicians, one surgeon, and two apothecaries are attached. Besides, there is a fever hospital, an eye infirmary, lying-in-hospital, and a charity for attending married women in their own houses. Gateshead has likewise a dispensary, attended by three physicians, four surgeons, and one apothecary. In all of the above institutions, the appointments are for life.

"Medical School.

"In January last, a medical school was established here, in which four months' spring courses of lectures were given. In future, six months' winter courses on medicine, surgery, anatomy, midwifery, materia medica, and chemistry, will be annually delivered. It promises considerable benefit to the numerous medical pupils of this district, which possesses every facility for teaching all the branches of medical and surgical science.

"Many imperfections of the present medical system, mentioned in some of the foregoing sections, are so obvious, as almost to point out their remedies, so that the hints, we take the liberty to suggest, may be very brief, viz. :—

"Suggestions.

- "1. The importance of uniformity of medical, surgical, and pharmaceutical, education, throughout the British empire.
- "2. The establishment of three medical faculties, one in each city, viz. London, Dublin, and Edinburgh, to confer degrees in medicine, diplomas in surgery, and licences in pharmacy.
- "3. Course of preparatory study and certificates, to be determined by a medical commission, appointed by government, and such to be altered and amended *only* by similar commission; the said commission to be constituted of an equal number (not being teachers) of English, Irish, and Scotch physicians and surgeons.
- "4. Examiners in no instance to be lecturers, and each to receive a fixed stipend, derived from government.
- "5. Examinations to be practical; each candidate showing on the subject his

knowledge of anatomy, and in a similar way proving his intelligence in the other branches of medical science, &c.

- " 6. Apothecaries only to be examined, in what appertains to pharmacy, &c.
- " 7. Members of each of the three branches of the profession to register their names on exhibition of degree, &c., in an office appointed for that purpose in each city, viz. London, Dublin, and Edinburgh. A list of such registries to be published annually.
- " 8. Physicians, surgeons, and apothecaries, to have *legal claim* to professional remuneration.
- " 9. Physicians and surgeons to possess *no legal claim* for value of medicines.
- " 10. Apothecaries not to prescribe, or pursue other vocations.
- " 11. All quacks, and quack and patent medicines, to be suppressed:
- " 12. Appointments to hospitals and dispensaries, not to be *for life*. The election of medical men to these institutions, if for a certain limited period in rotation, would equalise opportunities for acquirement of medical knowledge, and hence be useful to society, by improving the junior class of medical men, who must hereafter fill the places of their seniors; this arrangement would also be advantageous to the institutions, as younger men have more leisure to devote, and they could still enjoy the aid of those whom they succeed, in consultation, when necessary.
- " 13. Infirmeries and dispensaries might be much benefited, and at the same time encouraged to adopt No. 12 suggestion, were the legislature (on condition of compliance) to grant out of the poor's rates, a sum to each, bearing a certain proportion to the voluntary subscriptions possessed by such institutions; and further, that certificates from every infirmary containing 100 beds, whether metropolitan or provincial, so complying (and these only), be admitted to qualify students as hospital attendants for examination.
- " 14. Appointment of medical coroners, to be imperative throughout the kingdom; and due provision made for remunerating medical witnesses in every case.

" 15. All foreign graduates, qualified in recognised schools, to possess equal privileges with those of this country; reciprocal acknowledgment to be established between the faculties of these and other countries, where the standard of medical education is equal.

" 16. Druggists already established, to receive a certificate to dispense medicine as heretofore, provided they produce respectable medical reference as to character and capability; all other druggists to be precluded from dispensing medicine.

" *Inseparability of Medicine and Surgery.*

" Lastly, gentlemen, from the inseparability of the two departments of this profession, in a very large number of cases, we would beg to impress the necessity for physicians and surgeons being *strictly* examined, both in medicine and surgery; indeed we are disposed to believe both classes might beneficially go through *the same probation*, leaving to the subsequent choice of the graduate the walk in the Profession which he may prefer to pursue; thus removing awkward anomalies, ensuring to society, in every place, able practitioners; and tending to produce that division of labour, in the practice of so extended a science as medicine, as should guarantee excellence in every department. In conclusion we would beg to refer your honourable committee, for many enlightened views on a *proper medical constitution*, to Professor Double's admirable report to the Academy of Medicine, Paris. With sincere desires that your meritorious labours may be crowned with the best result, we have the honour to be on behalf of the Medical and Surgical Society of Newcastle-upon-Tyne, gentlemen, your very obedient servants,

" T. M'WHIRTER, M.D., *Chairman.*

" T. M. GREENHOW, *Secretary.*"

Newcastle-upon-Tyne, June 11th, 1834.

Foreign Medicine.

Observations on the Therapeutical Effects of the Crétacé.

BY M. REICH, OF BERLIN.

(*Journal de Hufeland, Janvier, 1834.*)

This empyreumatic oil has been discovered within the last year, by Professor Reichen.

back of Halle, in soot, acetic acid, and in all kinds of tar. It is of a whitish yellow colour, and the consistence of oil of turpentine. It has a very disagreeable taste and odour, somewhat similar to the animal oil of Dippel. MM. Téallier and Duparque have lately used it with success in alleviating the pains resulting from ulcerated cancers; but, from the experience of M. Reich, the most happy results in various affections are to be obtained from it. The following are the results of the observations made by the author, who in the first instance became relieved from its use.

During the winter 1831 and 1832 (he says) I was exposed for many hours in an open carriage to wet, and snow. After this I became attacked with acute pain in the right ileo-femoral articulation, my right thigh became insensible, and, as it were, completely paralysed, which disease resisted all ordinary means. Believing that the *tinctoria fuliginis* of Leclig owed all its beneficial properties to créosote, I decided on the use of this remedy. I commenced by mixing five drops of the créosote, in six ounces of an emulsion, and took two table-spoonfuls of it every two hours. The disagreeable taste of the medicine excited nausea, however I passed a more tranquil night. The next day I increased it to ten drops, and the following to twenty, which I took in four doses. The stupor and paralytic state of the limb entirely vanished. The pains of the articulation by the next morning had also left, but in the evening I had a relapse, also the sensation of stupor returned. I continued the medicine, taking twenty drops daily, for four successive days, all the symptoms disappeared, and I felt no more of them.

CASE II.—A lady, who had been the subject of two attacks of acute rheumatism, with swelling of the joints of the hands and feet in the month of July, was attacked on the 24th of August with stiffness, and a sensation of numbness in the limbs, which in general is the forerunner of a severe form of the disease. I prescribed for her the créosote, and in order to disguise its disagreeable taste, I ordered it in pills; one drachm in a sufficient quantity of the powder of althæa to make 120 pills. By the 26th the stiffness had greatly subsided; on the 28th she descended to her garden, and by the 6th September she was freed from all

rheumatismal pains, stiffness, and numbness; in fact the rheumatismal diathesis was entirely dissipated, for since then it has never returned.

CASE III.—A man 53 years of age, addicted to drinking spirits, had a severe attack of gout in 1832; alleviated at first by the mineral water of Wisbaden, though in 1833 it returned with greater severity. Numerous physicians were applied to, consequently various remedies were now adopted, which only gave him temporary relief. On the 21st of September another violent relapse occurred; the patient could get about only by means of crutches, his ankles and knees became swollen, and his strength was debilitated by nocturnal sweats, his tongue was red, and gums spongy. I gave him the créosote pills, five night and morning, and allowed him to continue them till the 22nd of November, by which time the patient was able to walk about in his garden.

Two cases of pulmonary phthisis are also described by the same author, in which the pills were administered with the most happy results; but as he has not chosen to prefix to them the stethoscopic sounds, we certainly are rather doubtful upon this point, for so frequently has pulmonary catarrh been cured, and mistaken for phthisis pulmonalis.

M. Reich has also made use of this medicament as an external application; his first experiment was on the body of a woman who had been dead three days; putrefaction had taken place, and the stench was insupportable; the body was sprinkled with distilled créosote water, which checked the progress of the putrefaction, and destroyed the unpleasant smell.

CASE IV.—A young man, affected with extensive confluent small-pox, whose body was covered by crusts, raised by a thick bed of pus, had the parts washed with an ounce of water containing one drop of the créosote, the disagreeable odour disappeared, and the ulcerations of the skin cicatrised.

CASE V.—Another young man was affected by scrofulous ulceration of the right leg, which had existed for eight years, though many times had nearly cicatrised, but the ulceration in a short time increased again. For eight months it had continued to increase in size,

and its edges were rugged and indurated. The créosote was prescribed, the part which was painful became less so, cicatrisation had commenced, but the patient was unwilling to continue the medicine.

In blennorrhagia and syphilis the author also states he has found much benefit from its use.

[The beneficial effects of this medicine in such various diseases, we fear, are too valuable to be true; but we are happy to inform the reader ere long we shall be able to speak with certainty; as at the present time there are several patients, both of Drs. Elliotson's and Roots', in St. Thomas's Hospital under its influence.—Eds.]

MR. CHITTY'S REPLY TO OUR REVIEW OF HIS WORK ON MEDICAL JURIS- PRUDENCE.

*To the Editors of the London Medical and
Surgical Journal.*

GENTLEMEN.—The general liberality of your Reviews assures me you will take pleasure in withdrawing the sting of criticism when you think it misplaced, and therefore I trouble you.

In page 725 of your review for the 5th inst. you refer to page 381 of my work, as incorrectly stating the *general* periods when the powers of procreating in men, or childbearing in women, cease; and you refer to instances of both sexes having evinced those powers at much later periods. I stated what I considered to be the *general rule*, and I also refer to the very instances as exceptions which you appear to have supposed I was ignorant of. With respect to the case in which you state Sir William Horne was concerned, I will, if you please, send you the decision in the King's Bench, and the papers on the cause. In K.B. the Court held that, as a Court of *Law*, they could not come to a *legal* conclusion, that it was impossible that a woman of sixty-three could not have a child. I argued the case afterwards in Equity, and the Court of Chancery compelled the purchaser to take the estate upon an *adequate indemnity* against the female having a child, so that the only result of the lawsuit was, that there is no *legal* supposition that a woman at sixty-three *cannot* have a child.

But your severest remark is, that I was *not*
VOL. V.

aware that the embryo or foetus was not equally alive from the instant even of impregnation. On the contrary, you will find in my Preface, page ix., I expressly refer to the absurdity of our legal distinction relative to quickening, and there make it one of the prominent reasons for urging legislators to attend to the subject. In pages 402 and 434 in particular, you will find I very explicitly condemn the legal distinction; I am sure, therefore, you will take pleasure in relieving me from the stigma of the ignorance ascribed to me in your page 725, where you say "*Had Mr. Chitty been aware of these facts, we feel convinced he would have commented on the defective state of the law,*" &c. &c. I observe, however, that probably you had not read so far as page 434 of my work when you wrote the comment.

Again; you will find in page 414, in the context at note (k), I particularly refer to the instance you state, of a child having been recovered *even two hours after apparent death*. I also refer, as regards the discovery whether a child has been born alive, to a fact I believe as yet unknown to lawyers, namely, the examination of the *ductus arteriosus* (see p. 410), and which shows that I refer to the *concluding* volume as to the other evidences. You will confer an obligation on the public and myself if you could find time to comment on this species of evidence, in an article in your valuable review*.

With respect to my not referring more frequently to foreign writers on medicine, I do confess I have a little national pride, and think we are too voracious after foreign materials; nor will I readily concede that our own countrymen are not the best, excepting in some points of surgery. I think English physiologists

* We have commented upon this evidence in our work on Medical Jurisprudence, p. 162, in these words:—"The obliteration of the umbilical arteries and vein, of the foramen ovale and the ductus arteriosus, evidently proves that the infant has been born alive. But these changes do not happen at the moment of birth, or sooner than two or three days, and often not before the first or second week; and consequently this evidence, in most cases, is of little value."

write with more sincerity. Besides, what contradictions do we find in foreign writers? for compare Leuret and Lassigne (*Histoire de la Digestion*) with Tiedemann and Gmelin on the same subject, and observe their contradictions. I assure you I have read, in the originale, nearly sixty recent French, German, and Dutch works, and I found the results so controversial that I deemed it better, as my work was principally for lawyers, to avoid the *affectation* of deep study, by omitting them; and, provided I am correct in the main, I am content. I assure you, that the accuracy of no physician or surgeon is implicated in my undertaking. At most, the *rough* proofs, and not the MS., were seen by Mr. Skey the able lecturer, and his corrections were little more than verbal, excepting in the article *DIGESTION*, in page 179.

I should be obliged by your explaining, that the *whole* work will be comprised in only *two volumes*, and the entire price will not exceed two guineas, with an allowance to legal and medical students, who may have the work at cost price.

I remain, Gentlemen,
Your faithful servant,
J. CHITTY.

Clapham, July 7th, 1834.

[In our review of Mr. Chitty's work, we endeavoured, as is our invariable custom towards authors, to do him justice, and the very favourable opinion we expressed of it is the best proof of our sincerity.

In reply to his statements in the above communication we have to remark, that though he gave the general rule as to the duration of fecundity in both sexes, he did not, in our opinion, attach sufficient importance to the singular exceptions which we noticed, or to many others that might be mentioned. We alluded to two distinguished members of our profession, one over 70 and the other near 90 years of age, who, within a few years, entered into matrimonial unions; and we might mention an eminent practitioner who, in his eightieth year, had four children, and received a piece of plate from the corporation among whom he resided. The point in dispute is highly important on the grounds of legitimacy and disposal of property; and we are pleased to observe, that our law courts have not at-

tempted to decide upon the duration of fecundity. We are much obliged to Mr. Chitty for his valuable information on the subject.

With respect to the question of quickening referred to in the Preface, p. ix. and pp. 402 and 434, we are bound to admit that there is a short sentence in each page, but there should have been more; and Mr. Chitty will find much stronger comments in our epitome than in his systematic work. We dwell upon the question, as the law regarding it is manifestly absurd, and we commented upon it in the work before us with regret, as we are convinced had it been more forcibly criticised by our author, it would be speedily effaced from the statute book. Moreover, we know that some barristers defend the existing law, and one gentleman of high legal and extensive information observed to us, on perusing the received opinion of the humanity or vitality of the fetus from the moment of conception, expressed in our review, that were the law to admit it ~~any~~ women could be executed, for as soon as they committed any felonious crime they would ~~use~~ the means to become pregnant; and he mentioned an instance of a woman who was tried for murder, and who was ordered to stand back in the dock before the passing of the fatal sentence, who submitted in that situation to sexual intercourse in order to plead pregnancy in stay of execution. But this objection appears to us to be invalid, because it is utterly impossible, in the present state of science, to decide positively whether a woman is or is not pregnant before the third month of utero-gestation. Supposing, however, that medical witnesses swore, to the best of their belief, a woman was pregnant, the execution ought to be stayed, for a doubt in favour of the laws of nature cannot be nullified by the arbitrary laws of man. And admitting that women become pregnant to escape death, it would be barbarous to order them to be executed, by which the lives of their unoffending offspring would be sacrificed. In justice to ourselves, we must state that our strictures on quickening were made on the text, p. 402, and not on the Preface, p. ix., or the summary of the laws relating to the generative function in p. 434. We therefore were justified in commenting upon the text as we found it.—Eds.]

LITHOTRITY.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—As lithotrity is becoming more generally adopted throughout the country, the following narration of the singular train of symptoms which succeeded this operation may not be unacceptable to many of your readers. The appearances after death show that it superinduced, in this patient, sympathetic irritation, and increased vascularity in the mucous membrane of the alimentary canal; and, though every care was taken to subdue the mischief, it extended so far as to baffle all our remedies. It was my wish to have transmitted a more brief account; but, as the patient was under treatment two months, I found it impossible to shorten it without destroying some of its most important features.

I am, Gentlemen,

Your obedient servant,

THOS. ROBT. TATHAM,

Surgeon, Huddersfield.

*Late Surgeon to St. Mary's Parish,
Nottingham, and its attached Hos-
pital and Dispensary.*

March 18, 1834.—Benjamin Hirst, æt. 50, near Huddersfield, of corpulent habit, has been suffering from a calculus in the bladder upwards of seven years, and during nearly four of the latter period confined to his bed, says he cannot alter his position, or sit up in a chair without causing much aggravation in the symptoms, as irritation at the neck of the bladder, and darting pains to the glans penis; for the last year and half he has had frequent desire to make water, and cannot retain more than four ounces of fluid at once without an irresistible desire to void it; the urine presents a little mucous deposit; general health upon the whole tolerably good; pulse 100. Upon inquiry, I find he has been under several practitioners in the neighbourhood three or four years back, but owing to his obesity they deemed it advisable not to perform the operation of lithotomy.

Mr. Valentine, surgeon, Nottingham, who has successfully performed lithotrity seven or eight times, having apprised me that he intended operating this morning at Wakefield, I

took the opportunity of witnessing him operate on a man sixty years old. I was so satisfied with it, that I requested him to accompany me to Huddersfield to see Benjamin Hirst, which he kindly acceded to.

Mr. V. succeeded in injecting six ounces of tepid water into the bladder, when he called out from pain of distension; it was as much as he could bear. He then introduced the percuter, immediately caught the stone, which he simply broke with a few strokes of the hammer. The whole period of the operation did not exceed five minutes. The patient showed much irritability of the bladder, and had involuntary dribbling of water during the operation.

19th A. M. Passed a restless night; perspired freely; complains of much soreness and heat in the bladder, and pain in making water; aching pains in his loins; headach, which he attributes to want of rest; surface natural; appetite unimpaired; pulse 112; discharged upwards of a quart of water, coloured with blood. A saline effervescing medicine was directed to be taken every three hours, and 3 ss. of carbonate of soda with 1 gr. of opium three times a-day.

21st. Much the same; required bleeding from the arm and opening medicine; scarce any detritus passed. Removed the following day to my house.

27th. Better; pulse 110, soft; urine still shows a cloudy mucous deposit; bowels open. Operated this morning in the presence of Dr. Walker and Mr. Robinson, Physician and Surgeon to the Huddersfield Infirmary, and Mr. Sargent, surgeon. I succeeded in injecting seven ounces of warm water. The first portion of stone I seized measured an inch and a quarter, the second an inch and a half, on the scale of the instrument, which required repeated strokes of the hammer to break, and appeared extremely hard. He seemed to bear the operation quite as well as before. To repeat the saline medicine every three hours, and the soda with opium three times a-day, tea and gruel. P. M. Complains again of pain in his loins, heat and soreness in the bladder and perinæum. Passed a pint of bloody urine.

28th. Had a tolerable night; sweat freely; pulse 116. Complains of soreness about the navel, and a disposition to strain at stool. Bowels not open; urine is free from blood;

no detritus come away. To continue the soda 3 ss. without the opium three times a day.

Ol. ricini, 3 vj. H. s. s.

29th. The castor oil operated freely. Tongue covered with a whitish fur; thirst considerable; had a severe rigor at noon, which continued three quarters of an hour; soon afterwards he was bathed in a profuse sweat; pulse 130; soreness of the navel gone, increased pain across the loins; heat and soreness of the perinæum and bladder much the same; urine less in quantity; no particles of stone have yet passed. Dr. Walker saw him at four o'clock, and wishes the following to be given: thinks I had better wait a little before abstracting blood; recommends a poppy head and chamomile fomentation to be used twice a-day.

℞. Potass. carb. 3 iiss.

Potass. nit. 3 j.

Aqua ad O ss.

M. ft. mist. alk., de quâ capiat. 3 j. cum mist. acid. 3 ss., 3 tiis horis in actu effervescentiæ.

℞. Acid. citric. 3 iss. aq. ad 3 iv.

Fiat mist. acid.

℞. Calomel. gr. iij.

Pulv. ipecacuan. gr. x.

Fiat pulv. sum. nocte maneque.

30th. Had a restless night; perspirations less copious; pain in the loins continues; bowels open; parted with several fragments of a tolerable size on going to stool.

31st. Tongue loaded; thirst considerable; surface cool and dry; has tenderness in the pubic region; pain in the loins about the same. Made near two quarts of water since last night, with a deposit of ropy mucus. P. M. 4 o'clock. Flushed countenance; headache; increased thirst; pulse 130, full, and hard; surface hot and dry. Continue mist. sal., et adde liq. antim. tart. 3 iiss.

V. S. B. ad 3 xvij., blood very sily and buffy.

Dr. Walker recommends the application of sixteen leeches to the hypogastrium, and the following pills:—

℞. Calomel. gr. ij.

Pulv. opii gr. ss.

Fiat pil. sum. 4tis horis.

April 1st. Had a better night; heat natural; pulse 126; less pain in the bladder; not so much tenderness on pressure. Made a tolerable quantity of urine, tinged with blood and mixed with much mucus. When the urine is

entirely drawn off, it adheres to the vessel with considerable tenacity. Bowels open.

3rd. Suffers from irritation at the neck of the bladder from frequently getting up to stool; pulse 108; surface cool; no tenderness in the hypogastrium; parted with another fragment. He omitted all the medicines as soon as he found the looseness to come on. To omit the calomel and opium, and the nitre in the saline medicine.

℞. Pulv. cretæ c. cum opio, ʒ ij.

Sum. 3tiis horis si opus sit.

7th. Urine slightly foetid; pain across the loins continues; less pain in making water; complains of thirst, and has a relish for beer; in consequence I have allowed him a glass to-day. Continue mist. effervesc.

9th. Tongue coated, dry in the centre; no appetite; pulse in morning 108, but at night nearly 120; pain in the loins abating; bowels confined.

℞. Ol. ricini, 3 vj. statim sumend.

10th. Bowels freely moved; appears rather better. Omit the saline medicine.

℞. Quinin. sulph. gr. iij.

Fiat pil. sumend. ter die.

To be allowed meat daily and a glass of beer.

22nd. Continues to do well; pulse 108; required occasional doses of opening medicine; deposition of mucus continues, though less viscid; foetor of the urine has been absent several days: it has been tested with litmus paper by Dr. Walker and myself several times, which it reddened; no fragments have come away lately*.

23rd. Operated in the presence of Dr. Walker, Mr. Robinson, Mr. Wrigley, and Mr. Highley, surgeons. I injected about seven ounces of warm water, as much as he could bear, and succeeded in breaking up seven portions of different sizes, the largest of which

* At a consultation with Dr. Walker, Mr. Robinson, and Mr. Sargent this morning, we consider the patient in a fit state to undergo another operation; and are also of opinion that the late severe symptoms have been produced by the presence of large angular portions, which create irritation; and that the stone should be broken as much as possible during the next operation, to allow of its free passage.

was rather more than half an inch in diameter. I once laid hold of a large portion measuring an inch and a half by the scale of the instrument, which, with one stroke of the hammer, flew from its teeth. I then contented myself with taking up moderate-sized portions, which which I could readily seize without giving much additional pain. The time, occupied in breaking up the fragments, might be from ten minutes to a quarter of an hour. The patient showed his usual irritability, and in the breaking of the last portion became rather faint. A little wine was given him, and, when put to bed, a drachm of tinct. opii. Afterwards he became very hot and flushed, sweat profusely for three hours; the water injected into the bladder was retained during that period. P. M. 8 o'clock. Surface natural; pulse 126; tenderness over the pubes on pressure, and has frequent stinging pains to the end of his penis, with desire to pass his water; makes with difficulty two ounces at a time; he has parted with a pint since morning, highly coloured with blood, a small quantity of detritus came along with it. A bran poultice was applied over the pubes, four grains of calomel with one of opium at bed-time, and a simple saline effervescing mixture every three hours.

24th. Had a tolerable night; pulse 114; found relief from the poultice; still has much difficulty in passing his urine; made twelve ounces last night, less tinged with blood; there is the usual ropy mucous deposit, which, when washed in clear water, assumes a flocculent appearance, like films of floating membrane. *℞ Repet. bol. cal. et opii, h. s., et cataplasma.*

25th. Appears to be doing well; pulse 108.

℞ Ol. ricini, ʒ ss. statim sumend.

27th. Had a bad night; countenance flushed and languid expression; tongue becoming furred; much thirst; surface hot; pulse 124, thready; tenderness increased in the hypogastrium; pain at the neck of the bladder about the same; mucous deposit very tenacious, similar to the brown sputa in inflammation of the lungs, it clings to the bottom of the vessel when inverted, and is become lately more viscous; complains of aching pains and soreness in his limbs; no large fragments have yet passed; bowels confined.

℞ Pulv. rhei, ʒ j., s. statim.

Dr. Walker concurs with myself in bleeding him to ʒ xvj. and to get him speedily under the influence of mercury.

V. S. B. ad ʒ xvj., blood very little inflamed.

Two scruples of strong mercurial ointment to be rubbed in night and morning. Tea and gruel.

28th. Restless through the night; much thirst; frequently sick; says he vomits the effervescing medicine; heat natural; complains of a diffused soreness all over the belly; bowels not yet moved. To omit the saline mixture.

*℞ Magnes. sulph. 3 iss.
Ess. Sennæ 3 iss.
Tinct. jalap. ʒ j.
Aq. menthæ pip. ad ʒ iss.
Fiat haust. statim sumend.*

29th. Had five copious motions yesterday; feels very low and faint; frequent sickness and hiccup; complains much of tormina and tenesmus, which have increased the irritation at the neck of the bladder considerably; gentle perspiration; pulse 104; motions of a natural and healthy appearance; urine becoming foetid. To omit the mercury. Chalk mixture with tinct. opii ordered to be taken every four hours.

May 1st. Diarrhoea still troublesome; gums sore; parted with more fragments.

2nd. One o'clock. A. M. During the last six hours the diarrhoea has been very severe; says he has been up six or seven times; dejections of a brown watery appearance; countenance pale; frequent sickness; sweats profusely; pulse 120, small; feels very feeble and sinking. Continue mist. creta 3tiis horis. 8 o'clock A. M. Says he thinks he has been up to stool twenty times since I left him this morning. The food which he took yesterday is come away without undergoing any change; lumps of hasty pudding, orange pulp, gruel, bread, &c. are readily detected; countenance much sunk; sickness and hiccup more frequent; much thirst; still sweats most profusely, pulse 112, feeble; three fragments are passed; says that he parted with many more whilst at stool.

*℞ Tinct. opii. 3 iss.
Aq. menthæ p. ʒ iss.
Fiat haust. statim s.*

R. Ext. hematoxyli, 3 ij.
 Creta ppt. 3 iiss.
 Tinct. opii 3 iij.
 Mucil. acaciæ 3 j.
 Syr. simp. 3 iij.
 Tinct. catechu. 3 vj.
 Aq. menthæ p. ad O ss. M. ft. mistur.
 Capiat 3 j. 3tiis horis.

10 o'clock P.M. Retained the laudanum draught, and was neither sick nor purged till after two o'clock, vomited twice since, and had two brown watery motions, containing fecal matter; cadaverous aspect; nose pinched; thirst and hiccup unabated; slight subsultus tendinum; says he feels a benumbed sensation over the chest; pulse 112; surface and extremities warm; made a pint of urine to-day, which yields a firm viscid mucus; less tenderness of the belly, and of pain at the neck of the bladder. Dr. Walker and Mr. Robinson consider him in great danger; they recommend the following pill.

R. Camphor. gr. iij.
 Pulv. opii gr. ij.
 Fiat pil. h. s. s.

Continue mist. hematoxyli 4tis horis.

A flannel, wet with turpentine, was applied over the abdomen. To be allowed some Sherry wine.

3rd. The flannel acted as a rubefacient. I visited him several times in the night; the sweating continued to be very profuse; at three o'clock got up to the close stool, vomited and purged at the same instant; seemed for a time quite exhausted; hands and feet became cold from exposure. I gave him some Sherry wine with another pill of camphor and opium, which induced a more comfortable state. To have wine and biscuit when he feels disposed.

Perstet in usum pil. camph. et opii 4tis horis.

4th. Since one o'clock yesterday morning he has taken a bottle of Sherry and half a bottle of ale: some light pudding, &c. Appeared better this morning. Hiccup came on to be very severe at three o'clock this afternoon; during each fit very yellow sour fluid is ejected; says the wine is too strong for his stomach; surface continues warm. Facies Hippocratica; voice altered; pulse 120, weak and fluttering; complains of more pain in making water; the urine presents the mucous sediment in the same quantity, but it is less viscid: on mixing clear cold water with it and stirring them together it produced a turbid

mixture, instead of presenting the before mentioned flocculent appearance, like films of coagulable lymph: it now has more the appearance of muco-purulent matter; passed a large quadrangular fragment. Cont. pil. 4tis horis.

R. Pulv. opii, gr. vj. Ft. supposit. administrand. h. s.

5th. More tranquil; drinks freely of some new wort (for beer), which he relishes, and particularly desired to have; perspirations less copious; urine scanty. Cont. pil. h. s. et supposit.

7th. Sickness and hiccup now almost constant; surface cooler; had, during the night, insensible discharge of both urine and feces; requests to have a mixture of beer and milk to drink. P.M.—Has vomited three pints of sour yellow fluid since morning. Cont. pil. h. s. et supposit.

8th. Much the same; instead of beer and milk, I have given him a mixture of lime water and milk, which agrees with him.

10th. Had less hiccup and sickness these two days; appetite has been middling; thirst considerable; pulse quick and weak; evacuations pass insensibly from him; dejections yellow, and of a proper consistence. Continue pil. h. s. et suppos. h. s.

In compliance with his frequent request to be taken home, I this morning conveyed him in a covered cart on springs, the bed being placed in for him to lie upon. He bore his journey very well, and seemed not in the least overcome by it. I gave him a dose of laudanum soon after he arrived home.

11th. Says he suffered very little inconvenience from the removal yesterday; slept well; he appears now much in the same state. Mr. Brook, surgeon, a neighbouring practitioner, kindly volunteered to attend him daily as long as his services might be required.

12th. Died at five o'clock this evening.

14th. Afternoon. *Autopsy.*—Mr. Brook assisted me in the examination. On making a longitudinal incision from the sternum to the pubes, four inches of thick fat were cut through before I reached the linea alba. The peritoneum, liver, omentum, stomach, spleen, and peritoneal surface of all the abdominal and pelvic viscera appeared healthy, no appearance of inflammation or adhesion of their surfaces; the kidneys were healthy, and imbedded in a large quantity of fat. The sto-

each was distended with air; its mucous membrane, and that of the duodenum and small intestines, were much injected, and of a diffused uniform redness, and so distinct was it in the jejunum and ileum throughout their extent, as to be visible through the peritoneal covering; there were also patches of red in the ascending transverse and descending colon. The following appearances presented themselves on examining the bladder, in the presence of Dr. Walker, Mr. Robinson, Mr. Wrigley, and Mr. Sargent, surgeons. Its parietes were unusually thickened and cavity contracted; the mucous membrane did not appear so vascular as we anticipated; the superior portion or fundus was pale, and showed scarcely any appearance of inflammation; on tracing its surface downwards towards the inferior portion, we found it to increase in colour to a reddish brown, intersected with small vessels of a leaden hue, which thickened towards its neck; the prostate gland appeared redder and more vascular than natural; the bladder contained a little glairy mucus, and a large portion of the calculus of an oval shape, with both ends broken off; it was flattened at the sides, presenting some rough scabrous points on its surface, sufficient to account for much irritation when it rolled in the bladder; it weighed nearly 3 ss, another portion 8 ij., with some small fragments, altogether weighing twelve grains. The entire stone appears to have weighed about six drachms.

Mr. Highley, jun., of Elland, has been kind enough to favour me with his analysis of the calculus. Its specific gravity is 1.6. The whole calculus was made up of well-compacted laminæ, forming round a central nucleus, each of which seemed to differ slightly in the shade from that which preceded or came after, while the inner was inclined to red; externally it was rough, and had on its surface a thin coating of reddish-brown shade.

Analysis.—Twelve grains of the nucleus and contiguous laminæ yielded nine grains of beautiful, small, white crystals of uric acid perfectly dried, the residue was a mixture of phosphate of magnesia and lime. The outer layers differed from the inner as follows:—

6.5 grains of uric acid.

3.0 grains of phosphate of ammonia and magnesia.

1.5 grains of phosphate of lime.

A little animal matter.

**MORISON'S PILLS, LATE ACTIONS
CONCERNING.**

IN our last number we referred to a case of Pursell v. Stevens, our note of which, from recollection of a very garbled statement in a daily paper, appears to be inaccurate. We now give a correct version of the facts, not so much on account of Mr. Pursell, a respectable practitioner at Stockbridge, whose character is unaffected by our unintentional error, as for the purpose of exposing the infamous artifices practised by the tip top quacks of the day; for it seems there must always be before the public some project of quackery, unless the law interfere to protect folly against knavery.

Mr. Pursell was called upon to prescribe for a boy under these circumstances, as stated by himself.

George Ray, æt. 13, a stout, robust boy, in the employment of a farmer named Judd, at Broughton, near Stockbridge, and residing with his parents, was, on Saturday, June 29, 1833, at a public house with his master, when the latter, for a "lark," took the boy to a privy, and, suspending him by the legs, attempted by force to thrust his head down the seat; the boy's struggles could not at first be overcome; more assistance was then obtained, and a second attempt succeeded. After this the boy was prevailed upon to take a glass of beer. On his return home the boy of course complained of giddiness in his head, and every precursor of apoplexy. As the small pox was in the neighbourhood, his mother, who was unacquainted with the brutal outrage, gave him some medicine, but, finding him no better, she applied to Mr. Pursell for

something to relieve his head. From the mother's account to him, Mr. Pursell was under the same mistake; and it was not till the following day, when the boy was getting worse, that Mr. Pursell was requested to see him, and observed his symptoms were very different from those of small pox. Upon inquiry, the real facts were ascertained. Mr. Pursell's subsequent treatment was judicious, and the boy recovered from a state of imminent peril. It seems the parents were unwilling to prosecute the boy's barbarous master. We have given the facts at full length, that the parish authorities may interfere, and make the cruel torturer feel how narrow an escape he had for his life. Had the boy died, the master and his crew would have been, every one, hanged.

Now for the Morison episode.—Morison sports a splendid equipage in Hampshire. A Miss Tomkins, of Broughton, for some reasons best known to herself, patronised Morison's Pills. She frequently called to see the child during his illness, and took notes. She also recommended the use of Morison's "Universal Pills." Morison finds it convenient and profitable to publish a newspaper for the purpose of puffing his quackery. Moat, his coadjutor and vice-president of "the College of Health," becomes accordingly proprietor of a newspaper with the captivating title of *The Christian Advocate*. In this paper appeared an advertisement of the eighty-fifth series of cases cured by Morison, in which was contained the libel. The remaining facts of the case, and the nature of the libel, will be sufficiently understood from the charge of Chief Justice Tindal, which we give at length, as it shows a tendency to protect the regular practitioner against the insults, at least, of quackery.

"**LORD CHIEF JUSTICE TINDAL.**—Gentlemen of the Jury, this is an action which is brought by the plaintiff against Mr. Stevens and Mr. Moat, who are concerned in the publication of a newspaper called *The Christian Advocate*, for a libel in one of the numbers of that paper, imputing to the plaintiff, who is a surgeon practising at Stockbridge, ill treatment of a patient under his care, accompanied with cruelty. The action is brought to recover a compensation in damages for the injury which this publication is in its nature calculated to inflict on the plaintiff, and also some remuneration for the distress of mind which he felt when he was so held up to public indignation and scorn for the alleged ill treatment of a poor child. It will be for you to say what is the fair and reasonable compensation he ought to receive for the injury he has sustained under all the circumstances of the case. It is quite clear, that the ground which has been urged as a defence has altogether failed the defendants upon this occasion. It is no answer at all, that a lady in the country, of an enthusiastic character, submits to the defendant a statement, which turns out to be fabricated, or at least very much exaggerated in its particulars; but, however, you are merely to assess the damages which the plaintiff has sustained: it is not a circumstance which you are to treat as affording a ground of defence to the present action. Indeed, it appears to me, from some parts of the libel, that it is not merely a dry statement of facts which takes place, but as taking place immediately before the eye of the person who is supposed to have given this statement to the defendant; this professes to give an accurate account of the course of treatment and cure of this individual, which seems only to have been put in for the purpose of inflicting a wound on the feelings of the plaintiff. It is not merely stated in the form of a letter or communication, but it gives their view of the course of treatment adopted. They call it—'From a Correspondent in Hampshire.—A dreadful Instance of Cruelty and Maltreatment practised on a poor Child by one of the Faculty.' One can hardly see that a man, who produces a publication with such enthusiasm as that, can have intended otherwise than to attack a man who was regularly initiated in the profession on purpose to make way for their own remedies, which they conceive to be useful, at all

events, for the purpose of serving themselves, in a pecuniary point of view, in selling and vending their medicines. As to the words with which they begin the statement, they are words evidently put into the publication after the letter had been written, and I doubt not after it had been received. In the course of her letter she states in one place that 'Mr. Pursell had been and pronounced the child worse, and in more danger than when he saw him last; squeezed his back where the blister had been, made the child cry, and then said, there is something wrong there; he must have another blister on the same part, and ointment to keep it open; leeches, powder, and lotion, the same as before.' Then he says, 'the mother told him she was quite sure the child was better, and that she should not attend to his orders any more, for she did not believe he tried to cure her child.' That is stepping out of the way, in detailing the treatment of a medical man, to say that the mother of the patient stated that; even if she had stated so, it would not have justified this attack, and in drawing your conclusion from the fact, it might be useful *that you should look at the difference between the practice of the regularly educated medical man, and the effect of this newly discovered remedy.* A person steps out of the course, and gives you an account of what the mother said, that she did not believe this person, who claims under the record, ever attempted to cure her child. The writer makes Mr. Pursell to call again upon the 25th, and when asked what he thought of the child, to have said, 'Oh, he is quite an altered person.' Mr. Pursell had previously seen some person to whom he said he could have cured the child long before, if he had been sure he should have been paid for it. A great calumny, in point of fact, for it is not justified, nor is it stated where the party is to be found, in order to have an opportunity of proving it, if it is true. It is a great calumny for a man who is attending a family in humble station, to charge him with leaving off that attention, and being guilty of such baseness upon a purely selfish feeling, and not exerting those faculties he possesses. That again is a circumstance in this case, which would stand quite clear of any enthusiasm about the good effects and virtue of these newly discovered pills, asserting, without reference either to

the mode of treatment, or to the virtue of the newly discovered remedy; a falsehood which imputes to him great baseness of mind.

"Gentlemen, it appears after the publication had been made, there had been a republication, in another shape, of the libel; I should not advise you to make that a ground for the increase of damages, but this is a question for you. It is evidence to show that Mr. Moat has not done the thing privately or unadvisedly, when, so late as the month of June after, he puts this justification on the record, which he withdraws in July, he has countenanced it afterwards. Now, gentlemen, this is the case.—The defendants both insisted upon it that all they had asserted was true; they had allowed it to remain on the record until last Friday, the 4th of July.

"It is asserted, upon the part of the learned Counsel for the defendants, that this is no aggravation of the offence at all, for it shows that, before the investigation, they thought it was true, but afterwards found it was false. It is this assertion which has kept the mind of the plaintiff in a considerable degree of anxiety; and I leave it to you to say, whether you think that shows any dignity of mind on the part of the defendant, or not first asserting it was true, then hesitating, and thinking they could not justify it. If it was meant to deter the plaintiff from proceeding further, by the fear which it might provoke in a weak mind, then it bears a different aspect and conclusion.

"The question of damages, which is all you have to determine, is one that belongs to yourselves: you will say, under all the circumstances, what is a fair and temperate remuneration in damages the plaintiff ought to receive for the injury he has sustained."

A correspondent has sent us some critiques upon the medical evidence at the inquest at York, reported in our last number, in which the virtues of Morison's Pills were discussed. Our report is extracted from a country newspaper. We withhold the comments at present, as we suspect we cannot trust to the accuracy of our authority as to the nature of the medical evidence.

MEDICAL JURISPRUDENCE.

WE apprehend medical practitioners will not be displeased to see now and then brief notices of occurrences in courts of justice relative to medical jurisprudence. We have latterly been led to examine some points on this subject, in reviewing Mr. Chitty's elaborate work; and we avail ourselves of this opportunity to give a short statement of two cases that occurred very lately. The first relates to the mode of stating a wound in *legal* form; the second is a case of infanticide, and illustrates the doctrine, that the infant must be born alive to constitute the crime. The report is deficient in not stating what was the evidence of non-vitality in the case. Let ignorant quacks tremble at the note at the conclusion of it.

The prisoner was charged with inflicting, "in and upon the right side of the head of the deceased, one mortal wound and bruise, of the length of three inches, and of the breadth of three inches," not stating the depth. On the authority of Lord Hale, it was contended it was necessary to state the depth also, although it was admitted it need not be stated accurately; however, it was held that as *common sense* did not require the length, breadth, and depth of wounds to be stated, it was not necessary they should be stated. —Rex v. Tomlinson, 6 C. and P. 370.

The prisoner was indicted at Oxford Assizes, 1834, for the murder of her bastard child. Two surgeons, Mr. Box and Mr. Hester, proved that the child had never breathed. The child was found in the water at Sandford Ferry. The learned judge (Park) held that the child must be wholly in the world in a living state to be the subject of a charge of murder; but if it had been wholly

born and is alive, it is not essential that it should have breathed at the time it was killed, as many children are born alive, and yet do not breathe for some time after their birth.—Rex v. Brain, 6 C. and P. 349. The reporters refer to Dr. Blundell's Lectures on Midwifery (p. 60), for a case in which that able practitioner removed a child from the mother, by the Cæsarean operation, thirteen minutes from the last respiration of the mother; in two minutes after artificial respiration was commenced, and the child was completely resuscitated by the continuance of the artificial respiration for fifteen minutes. The process of resuscitation has been often continued with ultimate success for a much longer period. In a further note to the same cause, a case is mentioned, for the terror of quacks, where a midwife, who was grossly ignorant of the art she professed, injured the head of a child before it was completely born, and the child was afterwards completely born alive, and died of this injury; it was held to be manslaughter.

Reviews.

A Practical Treatise on Medical Jurisprudence, with so much of Anatomy, Physiology, Pathology, and the Practice of Medicine and Surgery, as are essential to be known by Members of Parliament, Lawyers, Coroners, Magistrates, Officers in the Army and Navy, and Private Gentlemen; and all the Laws relating to Medical Practitioners. With Explanatory Plates. By J. CHITTY, Esq., Barrister at Law.

WE consider the elaborate and erudite work before us of such value, and especially the legal part of it, that we fulfil our promise by noticing the article on insanity.

Mr. Chitty first describes the passions, emotions, and mental feelings, and how far they are objects of medical or legal interference. His description of the good and bad effects of

the passions on mind and body is very ably given. He then comments upon the defective state of the law as regards the punishment of injuries to the passions and emotions, and explains the reason of it. He shews that verbal slanders may injure the health, and destroy life. He gives, among many, the following illustrations:—

“In the House of Commons, the Solicitor-General Pepys, on Tuesday, 18th March, 1834, mentioned a distressing instance of such existing defect in our law. A young woman had in early life been seduced by a man of title; but after living with him for a certain time she became ashamed of the course of life she was pursuing, and, taking the opportunity of escaping from it, she retired into a distant part of the country, where her seducer was unable to discover her. She obtained a situation, in which she conducted herself with so much propriety that she not only gained the goodwill of her employers, but was appointed to another situation in a public establishment. Several years after, her seducer discovered the place of her retreat, and having in vain made proposals for the renewal of their intercourse, he hit upon the expedient of depriving her of the means of subsistence, thinking that he should then succeed in his attempt to possess himself again of her person. He therefore published in the town where she resided the history of her early life. The consequence was that the unfortunate woman lost the esteem of the friends her good conduct had procured her, and she was deprived of the appointment by means of which she obtained her livelihood. Was not this woman entitled to compensation? Yet if she had brought an action against her persecutor, he would have justified, and she would have been turned out of court, with the aggravation to her misfortune of having incurred a useless expense. Unquestionably the law affords no compensation in such a case for the *malicious injury* to what might be termed her justly acquired *recovered character*.”

“If any doubt should exist in the mind of any one whether our law be not defective in not *punishing corporeally* those who wilfully occasion *injuries to the passions, emotions, affections or feelings of another*, let him read some of the able speeches of Mr. Erskine, especially those relating to the in-

juries of adultery and seduction, and examine the French law, which is much preferable; and consider the numerous instances in which persons, who have been injudiciously only fined for an offence recognised by law, have with exultation instantly thrown down the money to the officer, and contemptuously left the court*.”

Our author proceeds to describe the intellectual faculties, which he does with great ability and success, citing the best metaphysical and medical authorities, and embraces materialism and anti-materialism, which is succeeded by observations on the legal view of the mind and intellectual faculties at different ages, and when a person is deemed to be of unsound mind, with an exposition of the law on mental defects, idiotcy, lunacy, weakness, of mind. This article is, as we have already stated, one of the best, if not the very best in our language. It contains a host of opinions delivered by all our judges to the present period, but of these we can only find room for the eloquent and graphic exposition of Lord Erskine.

On Insanity. By Lord Erskine.—“The late Lord Erskine, in his speech in defence of Hadfield, for treason in shooting at the king at Drury-lane Theatre, thus argued:—‘The law as it regards this most unfortunate infirmity of the human mind, like the law in all its branches, aims at the utmost degree of precision; but there are some subjects, and the present is one, upon which it is extremely difficult to be precise. The *general principle* is clear, but the *application* is most difficult. It is argued by all jurists, and is established by the law of this and every other country, that it is the *reason of man* which makes him accountable for his actions, and that the deprivation

* “See Erskine’s Speeches, vol. v. 192, Mr. Erskine’s observations. In a late instance of a profligate injury to a father by seduction and desertion of his daughter, the defendant insultingly sent the 1000*l.* damages awarded by the jury to the plaintiff by a livery servant, with his compliments, and he would with pleasure send him another 1000*l.* the next morning, if he would send his second daughter to him for the intervening night, and he found her agreeable.”

of reason acquits him of crime. This principle is indisputable; yet so fearfully and wonderfully are we made, so infinitely subtle is the spiritual part of our being, so difficult is it to trace, with accuracy, the effect of the diseased intellect upon human action, that I may appeal to all who hear me, whether there are any causes more difficult, or which indeed so often confound the learning of the judges themselves, as when insanity, or the effects and consequences of insanity, become the subjects of legal consideration and judgment. I shall consider insanity, *first*, as it annuls a man's *dominion over property*; *secondly*, as it *dissolves his contracts* and other acts which otherwise would be binding; and *thirdly*, as it *takes away his responsibility for crimes*. If I could draw the line in a moment between these several views of the subject, I am sure the judges will do me the justice to believe that I would fairly and candidly do so; but great difficulties press upon my mind, which oblige me to take a different course. I agree that the law, in neither civil nor criminal cases, will measure the degrees of men's understandings, and that a *weak* man, however much below the ordinary standard of human intellect, is not only responsible for crimes, but is bound by his contracts, and may exercise dominion over his property. Sir Joseph Jekyll, in the *Duchess of Cleveland's case*, took the clear legal distinction, when he said, "*The law will not measure the sizes of men's capacities, so as they be compos mentis.*" And Lord Coke, in speaking of the expression *non compos mentis*, says, "Many times, as here, the Latin word expresses the true sense, and calleth him not *amens*, *demens*, *furiosus*, *lunaticus*, *fatuus*, *stultus*, or the like; for *non compos mentis* is the most sure and legal." He then says, "*Non compos mentis* is of four sorts, *first*, *ideota*, he who from his nativity, by a perpetual infirmity, is *non compos mentis*; *secondly*, he that by sickness, grief, or other accident, *wholly* loses his memory and understanding; *thirdly*, a *lunatic* that hath *sometimes* his understanding and sometimes not, *aliquando gaudet lucidis intervallis*, and therefore he is called *non compos mentis*, so long as he hath not understanding." But notwithstanding the precision with which this great author points out the different kinds of this unhappy malady, the nature of his work,

in this part of it, did not open to any illustration which it can now be useful to consider. In his Fourth Institute he is more particular. But the admirable work of Lord Chief Justice Hale, in which he refers to Lord Coke's Pleas of the Crown, renders all other authorities unnecessary.

"Lord Hale says, "There is a *partial* insanity of mind, and a *total* insanity. The former is either in respect to things *quoad hoc vel illud insanire*. Some persons that have a competent use of reason in respect of some subjects, are yet under a *particular dementia* in respect of some *particular* discourses, subjects, or applications, or else it is partial in respect of *degrees*; and this is the condition of very many, especially melancholy persons, who for the most part discover their defect in excessive fears and griefs, and yet are not wholly destitute of the use of reason; and this partial insanity seems not to excuse them in the committing any *offence* for its matter capital; for doubtless most persons that are felons of themselves, and others, are under a degree of partial insanity when they commit these offences. It is very difficult to define the invisible line that divides perfect and partial insanity, but it must rest upon *circumstances* duly to be weighed and considered, both by judge and jury, lest on the one side there be a kind of inhumanity towards the defects of human nature, or on the other side too great an indulgence given to crimes." Nothing can be more accurately nor more humanely expressed, but the *application* of the rule is often most difficult. I am bound, besides, to admit that *there is a wide distinction between civil and criminal cases*. If in the former a man appears, upon the evidence, to be *non compos mentis*, the law avoids his act, *though it cannot be traced or connected with the morbid imagination which constitutes his disease, and which may be extremely partial in its influence upon conduct*; but to deliver a man from responsibility for crimes, above all for crimes of great atrocity and wickedness, I am by no means prepared to apply this rule, however well established, when property only is concerned. In the very recent instance of Mr. Greenwood, the rule in civil cases was considered to be settled: that gentleman, whilst insane, took up an idea that a most affectionate brother had

administered poison to him. Indeed it was the prominent feature of his insanity. In a few months he recovered his senses. He returned to his profession as an advocate, was sound and eminent in his practice, and in all respects a most intelligent and useful member of society; but he could never dislodge from his mind the morbid delusion which disturbed it, and, under the pressure no doubt of that diseased prepossession, he disinherited his brother. The cause to avoid this will was tried here. We are not now upon the evidence, but upon the principle adopted as the law. The noble and learned judge who presides upon this trial, and who presided upon that, told the jury that if they believed Mr. Greenwood, when he made the will, to have been insane, the will could not be supported, *whether it had disinherited his brother or not*; that the act, no doubt, strongly confirmed the existence of the false idea, which, if believed by the jury to amount to *madness*, would equally have affected his testament, if the brother, instead of being disinherited, had been in his grave; and that on the other hand, if the unfounded notion did not amount to madness, its influence could not vacate the devise. This principle of the law appears to be sound and reasonable, as it applies to *civil* cases, from the extreme difficulty of tracing with precision the secret motions of mind deprived by disease of its soundness and strength. Whenever, therefore, a person may be considered *non compos mentis*, all his civil acts are void, whether they can be referred or not to the morbid impulse of his malady, or even though to all visible appearance totally separated from it; but I agree with Mr. Justice Tracy, that it is not every man of an idle frantic appearance and behaviour who is to be considered as a lunatic, either as it regards obligations or crimes, but that he must appear to the jury to be *non compos mentis* in the legal acceptance of the term, and that not at any anterior period, which can have no bearing upon any case whatsoever, but at the moment when the contract was entered into or the crime committed. The Attorney-General, standing undoubtedly upon the most revered authorities of the law, has laid it down, that to protect a man from criminal responsibility there must be a *total* deprivation of memory and understanding. I

admit that this is the very expression used both by Lord Coke and by Lord Hale; but the true interpretation of it deserves the utmost attention and consideration of the court. If a *total* deprivation of memory was intended by these great lawyers to be taken in the literal sense of the words, if it was meant that to protect a man from punishment he must be in such a state of prostrated intellect as not to know his name nor his condition, nor his relation towards others; that, if a husband, he should not know he was married; or, if a father, could not remember that he had children; nor know the road to his house, nor his property in it: then no such madness ever existed in the world. It is idiotcy alone which places a man in *that* helpless condition, where, from an original malorganisation, there is the human frame alone without the human capacity, and which indeed meets the very definition of Lord Hale himself, when referring to Fitzherbert; he says, "*Ideocy or fatuity, à nativitate vel dementia naturalis*, is such a one as decried by Fitzherbert, who knows not to tell twenty shillings, nor knows his own age, or who was his father." But in all the cases which have filled Westminster Hall with the most complicated considerations, the lunatics and other insane persons, who have been the subjects of them, have not only had memory *in my sense of the expression*, they have not only had the most perfect knowledge and recollection of all the relations they stood in towards others, and of the acts and circumstances of their lives, but have in general been remarkable for subtlety and acuteness. *Defects in their reasonings have seldom been traceable*, the disease consisting in the *delusive sources of thought*; all their deductions within the scope of the malady being founded upon the *immoveable* assumption of matters as *realities*, either without any foundation whatsoever, or so distorted and disfigured by fancy as to be almost nearly the same thing as their creation. It is true, indeed, that in some, perhaps in many, cases, the human mind is stormed in its citadel, and laid prostrate under the stroke of frenzy: these unhappy sufferers, however, are not so much considered by physicians as *maniacs*, but to be in a state of delirium, as from *fever*. There, indeed, all the ideas are overwhelmed, for reason is not merely disturbed, *but driven*

wholly from her seat. Such unhappy patients are unconscious, therefore, except at short intervals, even of *external objects*, or at least are wholly incapable of considering their relations. Such persons, *and such persons alone* (except idiots), are *wholly* deprived of their understandings, in the Attorney-General's seeming sense of that expression. But these cases are not only extremely rare, but never can become the subjects of judicial difficulty. There can be but one judgment concerning them. In other cases reason is not driven from her seat, but distraction sits down upon it along with her, holds her trembling upon it, and frightens her from her propriety. Such patients are victims to *delusion* of the most alarming description, which so overpowers the faculties, and usurps so firmly the place of realities, as not to be dislodged and shaken by the organs of perception and sense; in such cases the images frequently vary, but in the same subject are generally of the same terrific character. Here, too, no judicial difficulties can present themselves, for who could balance upon the judgment to be pronounced in cases of such extreme disease? Another class, branching out into almost infinite subdivisions, under which, indeed, the former and every case of insanity may be classed, is where the *delusions* are not of that frightful character, but infinitely various, and often extremely circumscribed, yet where imagination (within the bounds of the malady) still holds the most uncontrollable dominion over reality and fact; *and these are cases which frequently mock the wisdom of the wisest in judicial trials*, because such persons often reason with a subtlety which puts in the shade the ordinary conceptions of mankind; their conclusions are just, and frequently profound; but the premises, from which they reason, when within the range of the malady, are uniformly false;—not false from any defect of knowledge or judgment, but because a *delusive image*, the inseparable companion of real insanity, is thrust upon the subjugated understanding, incapable of resistance, because unconscious of attack.

“*Delusion*, therefore, where there is no frenzy or raving madness, is the true character of insanity; and where it cannot be predicated of a man standing for life or death for a crime, he ought not, in my opinion, to be acquitted; and if courts of law were to be governed by

any other principle, every departure from sober rational conduct would be an emancipation from criminal justice. I shall place my claim to your verdict upon no such dangerous foundation. I must convince you not only that the unhappy prisoner was a lunatic within my own definition of lunacy, but that *the act in question was the immediate unqualified offspring of the disease*. In civil cases, as I have already said, the law avoids every act of the lunatic during the period of the lunacy, although the delusion may be extremely circumscribed, although the mind may be quite sound in all that is not within the shades of the very partial eclipse, and although the act to be avoided can in no way be connected with the influence of the insanity; but to deliver a lunatic from responsibility to criminal justice, above all in a case of such atrocity as the present, the relation between the disease and the act should be apparent. Where the connection is doubtful, the judgment should certainly be most indulgent, from the great difficulty of diving into the secret sources of a disordered mind; but still I think that, as a doctrine of law, *the delusion and the act should be connected*.

“You perceive, therefore, gentlemen, that the prisoner, in naming me for his counsel, has not obtained the assistance of a person who is disposed to carry the doctrine of insanity in his defence, so far as even the books would warrant me in carrying it. Some of the cases, that of Lord Ferrers, for instance, which I shall consider hereafter, distinguished from the present, would not, in my mind, bear the shadow of an argument as a defence against an indictment for murder. I cannot allow the protection of insanity to a man who only exhibits *violent passions and malignant resentments*, acting upon *real* circumstances, who is impelled to evil from no morbid delusions, but who proceeds upon the *ordinary perceptions of the mind*. I cannot consider such a man as falling within the protection which the law gives, and is bound to give, to those whom it has pleased God, for mysterious causes, to visit with this most afflicting calamity. He alone can be so emancipated whose disease (call it what you will) consists not merely in seeing with a *prejudiced eye* or with *odd and absurd particularities*, differing in many respects from the contemplations of sober sense upon the

actual existence of things; but he only whose whole reasoning and corresponding conduct, though governed by the ordinary dictates of reason, proceed upon something which has no foundation or existence.' "

Here we must conclude our review of this work, and, in apology to our readers for so long an extract, remind them of the extreme difficulty they have to encounter in deciding on cases of mental imbecility, and the serious responsibility they incur, if they deprive a fellow-subject of his liberty, unless he really is of unsound mind, as we have proved in a recent number. We take leave of Mr. Chitty with high respect for the indefatigable industry and laborious research he has shown in the compilation of this part; and we entertain no doubt that if his second and last volume be as well executed, his work will not only be one of reference and authority, but one which will largely contribute to the improvement of the laws, and to the promotion of the happiness of mankind.

British Hospital Reports.

ST. THOMAS'S HOSPITAL.

Aneurism of the Axilla—Operation—Cure.

Martin Michael, aged 46, who has been employed in the gas works for the last fourteen years, and, during the time, was in the habit of carrying a hod on the right shoulder, was admitted on the 13th of March by Mr. Green into St. Thomas's Hospital. States that he has always enjoyed good health, and lived temperately. About six months since, on leaving his work, by accident he happened to place his hand on the upper part of his breast, where to his surprise, immediately below the clavicle, he discovered a tumour about the size of a pullet's egg, not in the least painful, but beating violently. Not finding any inconvenience from it, he took no notice of it, till about three months ago, though he had observed that it had somewhat increased in size. At this time he found that it rapidly enlarged, and extended further down towards the inferior edge of the great pectoral muscle; it was now painful, which was much increased when the arm was brought in contact with the side. Within the last three weeks its size has much augmented; the pain has been so violent, that he has had but little rest; he however continued his employment till six days ago. He then applied to a medical man for relief, who advised him to wash the part with salt and water, and gave him some blue ointment to rub on it. A few days afterwards he was recommended to the

hospital, and taken in by Mr. Green. The tumour at this time was about the size of an orange, situated immediately beneath the outer half of the clavicle, extended into the axilla, at which part it was extremely painful when touched. Mr. Green decided at once upon putting a ligature around the subclavian artery, ordered ten ounces of blood to be extracted from the arm, and a dose of house medicine to be administered immediately.

On Friday (the next morning) at 1 o'clock, he was brought into the operating theatre; the tumour was again examined before a number of students, not the least doubt could for a moment be entertained as to its nature, and Mr. Green proceeded with the operation in the following manner:—

The patient was placed in a recumbent position on the table, the shoulder and arm slightly depressed. Mr. Green made a semi-elliptical incision commencing at the external edge of the sterno-mastoid muscle, about an inch and a half above the clavicle, carried the incision downwards, and then outwards towards the trapezius muscle; the platysma myoides and cervical fascia were next divided, the jugular vein pushed towards the median line, some cellular tissue was next removed, the omohyoid exposed, the fascia immediately behind this muscle was carefully lacerated with the point of the director, when the acromial edge of the scalenus muscle was felt by the operator's finger, and the pulsation of the artery distinguished. Before, however, the needle was passed around the artery, the operator found it necessary to enlarge the opening, for which some of the external fibres of the clavicular attachment of the sterno-mastoid muscle were divided, after which the needle was carefully passed from below, and before upwards and backwards, and the ligature secured. Pulsation in the tumour immediately ceased, the wound was brought together by means of adhesive plaster, and the patient carried to bed.

10 o'clock, P.M. Scarcely any constitutional excitement; feels quite comfortable; pulse 80; tongue clean; inclined to sleep.

The parts united by first intention; no unpleasant symptoms supervened. House medicine was given occasionally to obviate costiveness, and he is now perfectly recovered.

WESTMINSTER HOSPITAL.

Syphilitic Iritis.

Ellen Young, about 22 years of age, came into the hospital on 1st July with iritis. At first she denied having been afflicted with syphilis, but subsequently acknowledged it. Her eye has been affected for five weeks previous to her admission, and she described the pain as exceedingly acute.

On her admission she was ordered

Sub. mur. hydrarg. gr. v.

Ext. colocyn. gr. x.

Fiant pil. ii., capiat stat.

When her bowels were well open, she was put on a mercurial course, and ordered to take two grains and a half of blue pill four times a-day.

5th Mouth slightly affected. Continue the blue pill.

8th. The mercury has produced the most satisfactory effects. Her mouth is very sore, and the eye considerably better; can see distinctly. Pain greatly diminished, and in every way going on most favourably.

Pil. hydrarg. gr. v.

Capiat omni nocte.

Elephantiasis.

A middle aged woman was admitted, with her leg enlarged and tumefied to an immense extent. These symptoms have appeared without apparent cause, and rapidly progressed. Her leg has now almost returned to its natural condition, by the use of blue pill, of which she has taken five grains a-day; fomentations of poppy heads and camomile flowers have been applied to the limb.

On last Saturday Mr. Guthrie announced to the pupils, that, on Saturday, July 19th, he would give them the history of the case which fell under his care, in which he tied the common iliac artery. The lecture will be given in the operating theatre of the New Westminster Hospital.

REAPPEARANCE OF MALIGNANT CHOLERA.

We regret to state that a case of blue cholera was admitted into the Westminster Hospital on Tuesday last, and another occurred at the Western Dispensary, Charles-street, Westminster. The first patient was removed to a workhouse, and died in a few hours; the second was pulseless when we received our information on Wednesday, and has since died.

APOTHECARIES' HALL.

NAMES of gentlemen to each of whom the Court of Examiners granted Certificates of Qualification, Thursday, July 10th.

James Boulton	Staffordshire.
John Elliott Catley	Cambridge.
George Frederick Codrington	Dorsetshire.
James Slapp Garthorpe	Norwich.
John Charles Rudkin	Brigg.
Robert Wood Thacker	Staffordshire.
John Moss Kirkman	Manchester.

BOOKS.

A Series of Anatomical Plates in Lithography, with References and Physiological Comments, illustrating the Structures of the different Parts of the Human Body. Edited by JONES QUAIN, M.D., Professor of Anatomy in the University of London. Fasciculus XIV. John Taylor.

The Principles and Practice of Obstetric Medicine, in a series of Systematic Dissertations on Midwifery, and on the Diseases of Women and Children; illustrated by numerous Plates. By DAVID D. DAVIS, M.D., Professor of Midwifery in the University of London. Part XXXIII. John Taylor.

CORRESPONDENTS.

Alumnus.—The nitrate of mercury is prepared by boiling metallic mercury in weak nitric acid and crystallising the liquor. It is very much used both internally and externally at the Hôtel Dieu, Saint Louis, and other Parisian hospitals. It is used daily in cancerous ulcerations of the skin and neck of the uterus, and is a most powerful caustic.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE XCIX., DELIVERED MAY 1, 1833.

GENTLEMEN,—The last class of diseases, which it will be in my power to consider in the few evening lectures remaining to be delivered in this course, is one of the greatest importance to the practical surgeon, comprehending *certain disorders of the genital and urinary organs*, which have not yet engaged our attention. When I state to you, gentlemen, that these diseases are numerous, often very painful, invariably a source of extreme mental anxiety to the patient, and frequently a cause of urgent danger, you are only informed of what a very short opportunity of studying disease must already have demonstrated to you. We will begin, if you please, with *diseases of the genital organs*, and first with those of the testicle.

It is an observation made by Sir Astley Cooper, that the body of the testicle is less disposed to disease than the breast; but that its tunics and the spermatic cord are liable to a great variety of diseases. I believe myself, that the testicle is quite as frequently the seat of inflammation as the breast, and it is admitted by the eminent surgeon, whose authority is justly so much valued, that it is an organ that is very often diseased, owing, perhaps, as he suggests, to the slow manner in which the blood returns from it against its own gravity, the occasional immoderate distension of the seminiferous tubes, its exposure to injury from blows or pressure, its sympathy with morbid conditions of the urethra and prostate gland, and the changes which it almost naturally undergoes in old subjects.

The classification of the diseases of the testicle, adopted by Sir Astley Cooper, seems to me a very good one: he divides them, first,

into those which are the result of common inflammation, acute, or chronic; secondly, into those which are of a specific nature, but not malignant; and, thirdly, he makes a class of others, which are both specific and malignant.

The first division comprises acute and chronic inflammation, and atrophy of the testicle. The second, embracing diseases, attended with specific but not malignant action, comprehends what Sir Astley Cooper names the hydatid, or encysted disease of the testicle, the irritable testicle, or neuralgia testis, the swelling of this organ frequently occurring in the disorder of the system termed *mumps*, ossific changes in the part, solid tumours of the epididymis, or testis, the scrofulous testicle, and what has been occasionally denominated the venereal sarcocele. The third division of the classification, including specific and malignant affections, comprises fungus hæmatodes and scirrhus. But, gentlemen, besides the numerous varieties of disease now referred to, you should make yourselves acquainted with several diseases of the coats of the testicle and spermatic cord, for which your professional advice may often be requested. Now, if you do not pay attention to the subject, you will be likely to get into very serious scrapes in practice, by confounding one disease with another, mistaking diseases of the body of the testicle either for hernial swellings, or hydroceles, or these again for enlargements of the testicle itself, and varicose swellings of the spermatic veins for herniæ, or herniæ for varicoceles. I am continually meeting with patients who either have herniæ, and not being aware of the nature of their cases, do not wear trusses, or who are wearing trusses on the supposition of their having herniæ, when, in truth, they have no such complaint.

I presume, gentlemen, you know that *acute inflammation of the testicle*, when it arises from gonorrhœa, or some other kind of irritation in the urethra, is frequently, though very absurdly, termed *hernia humoralis*. It is often excited by disease in the latter passage, especially strictures, and still more frequently by the means ordinarily employed for their

cure, namely, bougies, the irritation of which becomes the cause of the affection of the testicle. When inflammation of the latter organ is thus excited by disease in the urethra, it is preceded by soreness or irritation about the membranous and prostatic portions of that canal; the spermatic cord becomes swollen and tender, and in particular the vas deferens, which seems much thickened, and is extremely painful when handled. When the case is still further advanced, the swelling extends to the whole of the testicle, and you will observe, that the hardest part of it is the epididymis. So considerable is generally the enlargement of the organ in every severe case, that the scrotum is exceedingly distended, its rugæ are effaced, and its surface is completely smooth. Painful as the inflamed testicle is itself, a still greater degree of suffering is often experienced in the lumbar and inguinal regions, with great uneasiness about the hip and thigh. Sometimes the agony in the part affected seems to have paroxysms of increased severity, which are alleged to depend upon spasmodic contractions of the fibres of the cremaster. The scrotum, besides losing its naturally corrugated appearance, is also reddened. With these symptoms, gentlemen, you will notice an acceleration of the pulse, constipation, restlessness, thirst, heat and dryness of the skin, and other symptoms of inflammatory fever. The blood, taken away from the patient, is also found to be buffy. Sometimes the stomach is a good deal disordered sympathetically, and nausea and even repeated vomiting may occur. I once attended a man for an acute inflammation of the testicle, who at the same laboured under so obstinate a suppression of the stools, and such a repetition of vomiting, that a suspicion of strangulated hernia was created for a short time, but quickly abandoned on a careful examination of the swelling. In fact, a general enlargement of the testicle, like that from acute inflammation of the organ, is not at all likely to be mistaken for any kind of hernia, excepting the congenital, because in the case of bubonocoele you are able to feel the testis at some point or another below the hernial tumour. I should say, then, that there would be no excuse for you, if you were to confound these affections; a mistake in the diagnosis could only proceed from gross ignorance or the most supine carelessness.

As already explained, gentlemen, inflammation of the testicle may arise from irritation in the urethra, which, in some shape or another, is its most frequent cause; it may also be the consequence of external violence, and is often purposely produced by various surgical proceedings, employed for the radical cure of the disease named *hydrocele*. Sometimes you find inflammation of the testicle brought on by the pressure of badly-constructed trusses; sometimes as one of the effects of the disorder of the system well known by the appellation of *gump*.

When the testicle inflames and swells in gonorrhœa, the pain in making water and the discharge of matter are almost always suddenly diminished, or even suspended; a circumstance, ascribed by some pathologists to metastasis; and by others to sympathy between the urethra and the testicle. All that I can say upon this point is, that we seem to know little more than the fact itself, which is exemplified, I think, with remarkably frequency in patients, who, while they have a clap, take rough exercise, indulge in wine, and live altogether too freely. One thing, gentlemen, here merits your attention, and it is perhaps what you would not have expected, namely, that the swelling of the testicle does not always come on exactly at the period when the inflammation in the urethra is worst, but frequently when it is on the decline, or even nearly cured. Sometimes, be it likewise remembered, the inflammation of the testicle is not followed by any diminution or stoppage of the discharge, a fact clearly overturning the doctrine of metastasis, viewed as an essential thing in the explanation of the cause of the disease. A suspicion is entertained that the inflammation is sometimes propagated to the testicle from the mouth of the vas deferens. Mr. Hunter did not, however, adopt this view, because he found a swelling of the testicle to be as frequent in gonorrhœa, where the inflammation did not extend further than an inch or so from the orifice of the urethra, as where it reached to the neck of the bladder. Another idea is, that a swelling of the testicle is particularly disposed to come on when gonorrhœa is suddenly checked by the employment of copaiba, cubebs, or astringent injections; but, as far as I have been able to judge, the correctness of this opinion may be doubted, and many very experienced surgeons believe that they have seen an inflammation of the testicle arise as frequently under other modes of treatment as that now alluded to. At the same time, I feel it right to mention, that Sir Astley Cooper inclines to the belief that injections really have a tendency to bring on hernia humoralis, especially when they are made to pass far into the urethra. Notwithstanding what I have stated as Mr. Hunter's view, I would not have you suppose that inflammation may not sometimes extend to the testicle from the urethra, by the course of the vas deferens; and Sir Astley Cooper describes certain appearances noticed in the dissection of the urethra of a criminal who had been executed, which confirm the possibility of this occurrence. The man had a gonorrhœa at the time of his death, and when his urethra was cut open, although the inflammation was greatest in the first three inches of the canal, yet it extended also to the membranous portion of it, and even blood had been extravasated under its mucous membrane. Under such circumstances, the verumontanum, the termination of the duct of the vesiculae seminales, and the vasa deferentia in the urethra,

participate in the inflammation, which may then extend along the vas deferens to the cord epididymis, and testicle.

One fact, relative to this subject, is certain, which is, that the inflammation of the testicle rarely or never comes on in the early stage of gonorrhœa, but usually between the tenth day and the end of the third week. You will find, also, that when the pain and swelling of the testicle begin to abate, the running very commonly returns. Within the tunica vaginalis there is generally a quantity of serum effused, which, after the inflammation has abated, is absorbed again. We find likewise that coagulable lymph is thrown out within the same membrane in the form exhibited in the preparation, which I now pass round for examination. Lymph is also effused in the interstices of the glandular part of the testicle, occasioning considerable hardness, the remains of which will often continue a very long time after the inflammation has been cured.

The treatment of acute inflammation of the testicle must, of course, be antiphlogistic, comprehending quietude and even the horizontal posture in bed, if the case be a severe one. When the patient is young and robust, the swelling considerable, and the pain in the lumbar region violent, you should have recourse to venesection, and this pretty freely; and I may say, that, in all cases, leeches, saline purgatives, and low diet are absolutely necessary. If your patient cannot procure leeches, you may puncture the veins of the scrotum, whereby you will often succeed in obtaining a copious and beneficial discharge of blood. With respect to local applications, you may employ cold evaporating lotions, or, if the patient seem to derive most relief from emollient poultices and fomentations, these may be used. Perhaps, in very severe cases, the latter ought always to be preferred. But, gentlemen, nothing will lessen the patient's suffering more effectually, than the plan of taking off the weight of the testicle from the spermatic cord with a bag-truss or suspensory bandage; it has, indeed, the greatest effect in diminishing the pain experienced in the back and inguinal region, particularly when assisted by bleeding, saline purgative medicines, and the occasional exhibition of eight or ten grains of the compound powder of ipecacuanha. When the disease has arisen from the irritation of bougies, their employment must, of course, be suspended. One plan that has sometimes proved very expeditious in stopping the inflammation, and bringing down the swelling, is that of prescribing the tartarised antimony, so as to keep up a degree of nausea; but the practice is not commonly adopted, because patients submit more readily to the other means of relief which I have specified.

You will generally observe, gentlemen, that a considerable hardness of the testicle, and especially of the epididymis, remains after the inflammation has been completely removed, sometimes during the rest of the patient's life;

now Mr. Hunter suspected that, in some cases of this description, the canal of the epididymis might be impervious, and the function of the testicle annihilated. However, this suspicion does not coincide with the examinations instituted by Sir Astley Cooper, who says, that, when the swelling is at the lower part of the epididymis, it is seated in the cellular tissue of the vas deferens, where it forms its first convolutions, and is not an effusion within the cavity of the duct. The induration, according to his researches, frequently affects merely the tunics; and when situated in the upper part of the globus major, it arises either from lymph effused in the cellular substance between the coni vasculosi, or else from a sac filled with a viscid fluid.

For promoting the dispersion of the chronic induration, remaining after all acute inflammation is over, you may employ camphorated mercurial ointment, with or without two scruples or a drachm of the hydriodate of potash in each ounce of it. Or you may try poultices of vinegar and oatmeal, or the lotion of the muriate of ammonia, where friction cannot be borne. In some cases, good seems to be produced by internal alterative medicines, as the compound calomel pill, and sarsaparilla, or the tincture of iodine.

It is well known that acute inflammation of the testicle, taking place as a consequence of gonorrhœa, or irritation in the urethra, rarely suppurates; but when it is produced by external violence, the chance of an abscess is greater.

Sometimes, gentlemen, you will meet with examples of a *wasting away of the testicle*; a more or less complete absorption of it, technically termed *atrophy*. This may follow the subsidence of acute inflammation of the organ; but more frequently when such inflammation has been brought on by external violence, than when it originates as a consequence of gonorrhœa. No doubt, under these circumstances, the structure of the testicle has been irreparably damaged by the inflammatory process; and probably, in some instances, the atrophy may depend upon an obliteration of the vas deferens; for, in the museum of St. Thomas's Hospital, there used to be a testicle in this condition, the vas deferens of which could only be filled with quicksilver for about half an inch of its extent from the abdominal ring towards the testicle itself. This fact is reported in Sir Astley Cooper's work. An atrophy of the testicle sometimes takes place without any previous inflammation of it: the pressure of a truss on the spermatic cord will produce it; and you will find many curious cases recorded by Baron Larrey, where sabre wounds about the occiput and nape of the neck were followed by atrophy of the testes.

The testicle is subject to a *chronic enlargement*; whether it should be called *chronic inflammation*, I cannot exactly say: it usually commences with hardness and swelling of the

epididymis, at first attended with but moderate uneasiness, scarcely amounting to pain; at length, the glandular part of the organ becomes involved, and the testicle seems rather larger and more tender than that of the other side. If the disease arise from a blow, then it may begin in the body of the testicle, which may present a globular, instead of its natural oval form, and sometimes, though enlarged and altered in shape, it has no inequalities upon its surface. In other instances, however, it is at first unequal, so that knobs can be felt upon it; and this, according to Mr. Brodie, is usually the case in the beginning, a general uniform enlargement, without any knobs, being the more advanced state of the disease. The case is rarely so painful as to compel the patient to keep himself quiet, and refrain altogether from labour and exercise. In some cases, you will perceive, that a clear transparent serum is effused in the tunica vaginalis, constituting one of the forms of disease, to which the term *hydro-sarcocele* is vaguely applied. These two preparations, which I pass round, illustrate what is meant by the expression, namely,—a chronic enlargement of the testicle, joined with a collection of a serous fluid in the tunica vaginalis. In ordinary cases of this chronic enlargement of the testicle, the spermatic cord is not hardened, but its veins are somewhat enlarged; and when the disease has existed some considerable time, and has attained magnitude, the patient complains of pain and a sense of weight in the loins and thigh.

This chronic inflammation of the testicle, which has been well described by Mr. Brodie, leads to the production of a yellow tubercular substance in the texture of that organ; an unorganised yellow matter, collected at first in small masses, but afterwards in larger ones at certain parts of the testicle, while, in other places, you may observe the glandular structure quite healthy. In a later stage, the yellow matter, which he thinks is secreted within the tubuli testis and epididymis, assumes a hard consistence, and is generally laminated. This is a disease which is met with in various unhealthy states of the constitution, whether connected with rheumatism, syphilis, or other causes. It is often met with in persons who have been scrofulous in their youth, or whose constitutions have been broken by the long use of mercury. What has been termed the *venereal varicocele* is only one variety of it. According to Sir Astley Cooper, when a solid effusion has taken place in the seminiferous tubes, or even in the substance of the testicle, or epididymis, the disease may be cured by the strict observance of the recumbent posture, and the exhibition of three grs. of calomel and one of opium night and morning, so as to keep the gums affected for a month at least, with a black dose, and fifteen or twenty minims of the liquor antim. tart. every fourth morning. The topical treatment should consist of leeches twice a week,

and a lotion composed of the liq. antim. tart. ʒ v. and one ounce of spirit of wine.

No doubt, gentlemen, you have all heard of *granular protrusions*, or *fungous growths* from the testicle. These may follow the formation and bursting of an abscess in the part; or they may occur in the advanced stages of chronic inflammation of it. At one point, the testicle adheres to the skin, inflames, and ulcerates; and then, through the ulcerated opening, a fungus of small size at first projects, but, gradually acquiring greater bulk, makes its way through openings, not only in the tunica vaginalis, but in all the investments of the scrotum.

Now, according to Mr. Brodie's investigations, you may trace on the surface of this fungus the same kind of yellow matter, found in the glandular portion of the testicle, which glandular texture itself likewise protrudes, until no part of the testicle is left within the scrotum, and the spermatic cord can be distinctly traced into the centre of the fungus. In a still more wasted condition of the glandular structure, the cord, in fact, terminates in a small tubercular mass, the only remains of the organ.

With respect to this kind of *fungous*, or *granular* protrusion of the testicle, I may also remark, that the height to which it rises prevents the skin from healing over it; but it may be reduced by the pressure of a dossil of lint fixed on it with adhesive plaster, or it may be got rid of with escharotic applications. However, the surest mode of cure is that of cutting away the protruding mass on a level with the inner reflexion of the tunica vaginalis, making two semicircular incisions, and afterwards bringing their edges together. This plan is not, however, approved of by Mr. Brodie, because, in doing it, you actually slice away the tubuli testis; and hence, he prefers sprinkling the fungus with red precipitate, and giving mercury. Then, as soon as healthy granulations form, he dresses the sore with a solution of the sulphate of copper in the camphor mixture. I believe it to be a very good practice, when abscesses of the testicle leave deep fistulous openings, to prescribe calomel and opium, in the manner directed by Sir Astley Cooper, and to inject into the fistulæ a lotion of the sulphate of copper, or oxymuriate of mercury.

Gentlemen,—I next invite your attention to what is termed the *irritable testicle*, or *neuralgia testis*; a case analogous to tic douloureux and neuralgia in other parts. It is a highly sensitive and painful state of the organ, often without any very obvious cause, the suffering produced by it being frequently of the most excruciating kind, and of long duration, though subject to occasional remissions. The part is but little, if at all, swollen; and, on dissection, no change of structure can be detected. One example, however, of this affection in a medical student, in which I was lately consulted, and in which Sir Astley Cooper

was also kind enough to give his advice, had been attended with repeated swelling of the testis, though mostly it remained with scarcely any perceptible change of size. The most successful treatment consists in giving large doses of the sulphate of quinine or carbonate of iron; or, when the disease assumes an intermittent type, you may prescribe the liquor arsenicalis. Opium, the acetate of morphia, the extract of conium, hyoscyamus, and other narcotics, may also be given. If the secretions of the skin and liver be defective, try calomel, opium, and antimony, in combination.

As local applications, I may recommend ice, or a plaster composed of one-third of the extract of belladonna and two-thirds of soap cerate. This is a disease in which the ointment of veratria deserves a trial.

In the case which I alluded to as having occurred in a medical gentleman, the belladonna plaster, with small doses of opium, ipecacuanha, and calomel, and his removal from London to a watering place, produced great relief for a time; but, when I last saw the patient, he was not entirely well. No doubt the neuralgia testis frequently depends upon some disorder of the system at large, the removal of which is an essential thing in the cure. That you may have severe pain in the testicle also, from sympathy between this organ and other parts, without any alteration of its structure, we see illustrated in cases where great agony in the testis is experienced on the descent of a calculus from the kidney into the ureter. You may notice, however, in particular instances, a degree of swelling of the part, a varicose fulness of the spermatic veins, or even some hardness or prominence about the epididymis.

The next disease of the testicle meriting your consideration, gentlemen, is the *Scrofulous Testicle*. The secreting glands are rarely affected with scrofula; but this organ forms an exception. Even in young children it becomes enlarged and hardened, without pain, and remains in this indolent state for many weeks, months, or years, and then, as the health improves, gets well. More frequently the disease occurs towards puberty, preceded or accompanied by some other marks of scrofula, and sometimes it affects both testicles. Scrofulous disease of the testicle is remarkable for its indolent character, and the little pain attending it; you perceive a trivial swelling of some part of the organ, mostly the epididymis; and afterwards a small superficial lump at another point. These little tumours increase, and by degrees create greater uneasiness in the part. The skin becomes adherent to them; they suppurate; the abscesses burst, but discharge only a scanty quantity of matter; and the openings, having little tendency to heal, remain fistulous. At length the testis sometimes diminishes and wastes away, until but a small portion of it is left; but more commonly the organ is not entirely destroyed, and a considerable portion of the glandular struc-

ture remains, as you observe in the preparation numbered 835, and which I now pass round for your inspection.

The treatment of the scrofulous testicle is to be conducted on the same principles as are applicable to other strumous forms of disease. You may prescribe rhubarb and carbonate of soda in equal proportions (ten grains of each), to be taken once or twice a-day. You may give the liquor potassæ, preparations of iodine, or tonics of various kinds, according to the circumstances of the case, and the effects which you observe to be produced by such means on the part and the whole system; or, in other words, the general health. With respect to iodine, I like the way in which it is prescribed by Lugol better, than the less diversified mode in which we employ it. But this is a subject, which I explained to you when we were considering the treatment of scrofula in general.

Another more serious affection of the testicle has gone under the names of *Cystic Sarcoma*, and *Hydatid Disease of the Testicle*, though the latter term seems to me objectionable, as conveying the erroneous notion that hydatids exist in the part. The morbid mass into which the organ is converted, is partly composed of a solid structure, and partly of cysts, varying in size from that of a large pin's head to that of a small marble; some of them containing a thin transparent yellow serum, and others a more turbid fluid. It is a disease that is seen chiefly between the ages of thirty and thirty-five, and is sometimes mistaken for hydrocele, though the shape of the tumour ought to serve as a criterion, for it is oval, and not pyriform, like that occasioned by a collection of fluid in the tunica vaginalis, for ascertaining which last case we have likewise other circumstances, which I shall hereafter notice. The particular character, however, of cystic sarcoma of the testicle cannot always be known with certainty previously to the examination of the part after its removal by operation. It is not malignant, as it never extends to other parts, though it may be conjoined with medullary sarcoma, which is itself malignant. No constitutional or local treatment is of any use; for, gentlemen, this disease is truly an organic one, accompanied by a total disorganisation of the testicle, and changes of structure, leaving no possibility of a return of the part to its healthy state again. The pain caused by the weight of the tumour on the spermatic cord, and the annoyance of its bulk, frequently compel the patient to submit to castration.

In the next lecture, gentlemen, I will make a few observations on malignant diseases of the testicle; those which we have now been contemplating, though attended with specific action, are not regarded as malignant, according to the meaning of this term as sometimes adopted.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XXVIII.

Recapitulation—Apoplexy—Occurring with various conditions of the Brain—Simple or Nervous Apoplexy without organic change—Its occurrence in other Diseases—Serous Apoplexy—Opinions of Abercrombie—Sanguineous Apoplexy—Comparative frequency of its situations—Absorption and Organisation of the Clot—Occurrence of Apoplexy at an early age.

GENTLEMEN,—We were occupied at our last meeting in considering some of the most prominent symptoms of meningeal inflammation; and I beg of you to recollect, that all these symptoms, with the exception of pain, are those which ordinarily characterise inflammation of the substance of the brain itself, and are to be explained by referring them to some lesion in the functions of that organ. It appears, then, that the symptoms of meningitis, with the exception of pain, are symptoms of an affection of the brain itself; and this is a point which you must always bear in mind, when you agitate the question as to the possibility of making a diagnosis between meningitis and encephalitis. We have a set of symptoms characterising meningeal inflammation, the majority of which belong to irritation of the brain itself; and we find that these may exist with or without any *perceptible* alteration in the cerebral substance. Now, in cases where you suppose the existence of meningeal inflammation, and find these symptoms present, it would be venturing too much to assert that there was no complication with organic disease of the brain; and therefore we must conclude that, in most cases, it is nearly impossible to distinguish between inflammation of the substance of the brain and of its membranes.

In speaking of the more important symptoms of cerebral inflammation, I alluded particularly to convulsions, and stated, that, as far as my observations went, this symptom, formidable as it may appear, is not in reality so unfavourable as it is generally thought to be. In fact, there are many cases of affections of the brain accompanied by convulsions, in which the danger is by no means so great as in others of a different description; and many of the worst cases are those in which convulsions are absent, or only trifling. I think we may look upon convulsions as being more or less a source of relief to the brain when labouring under the excitement of irritation or inflammatory disease. You are all aware, that one of the great functions of the brain is to regulate and control the motions of the muscular system. If a man exercises his limbs violently for some time he

becomes tired and exhausted; he cannot pursue the same exercise any longer, for, in addition to whatever the muscular system may suffer, there has been a great expenditure of nervous energy; and if he should attempt to keep up the same exertions, such a degree of muscular and nervous debility is superinduced that syncope is the consequence. Now, the expenditure of energy produced by the supply of nervous power to the muscles seems to bear a strong analogy to the secretory discharges from other viscera. In the case of irritation or inflammatory affections of other organs, you are all aware that there is nothing which gives such speedy and effectual relief as supersecretion, or an increased action of the secreting vessels of the affected organ. Now, if we look upon the expenditure of nervous energy in the same light (and I see no reason why we should not), we can easily conceive why it is that convulsions relieve the irritation of an over-excited brain. I drew your attention strongly, at my last lecture, to the curious and important fact, that if we compare apoplexy and epilepsy, with respect to the danger and the chance of disorganisation attendant on each, we shall find the danger is infinitely greater, and the chances of organic change more numerous in the former than in the latter. In epilepsy, where the convulsions are violent, we seldom have a fatal termination of the fit, and there is rarely lesion of the substance of the brain, until the disease has lasted for a great length of time. This is not the case in apoplexy. Here, as I have already stated, we have two cases of active determination to the head: in one case there are no convulsions, and we frequently find the result to be death, or extravasation with paralysis and slow convalescence; in the other, we have violent convulsions, followed by rapid recovery and no disorganisation. From this it would seem reasonable to conclude, that convulsions are a mode of relieving the brain adopted by nature, and that their occurrence in hydrocephalus should not be looked upon as unfavourable. Now, if this be true, it must strike you, that nothing can be more dangerous and improper than to take any steps to control an attack of convulsion during the prevalence of hydrocephalic symptoms. The true mode of treating them is to adopt measures calculated to relieve irritation of the brain, and not hazard the patient's safety by following the ordinary but mischievous mode of attempting to control the salutary efforts of nature. I allude here particularly to the practice of administering opiates and antispasmodics, a practice which I firmly believe to be fraught with danger.

Gentlemen, we have to-day to consider another form of cerebral disease, scarcely less important than those with which we have been hitherto engaged. In all the former instances we find the determination of blood to the brain followed by that organic change which we term inflammation. But we may have accumulations of blood in the brain unaccom-

panied by inflammation, and this brings us to the consideration of apoplectic disease. The term apoplexy, as I suppose you all know, is derived from a Greek word, signifying a stroke or blow. It is a term which, in the present state of medicine, has been very frequently abused, or at least employed in very different senses, and hence the many erroneous opinions respecting it. The true meaning of the term expresses an alteration of the phenomena of the life of relation, that is of the functions of the cerebro-spinal system. In taking a view of the nature of this alteration, we find that the attack generally comes on in a sudden manner, and that the functions of the brain are partially, or completely suspended. You are aware that the manifest phenomena of the life of relation are those which belong to *sensation, muscular motion* and *the intellect*, and that the system of the life of relation is composed of the brain, spinal cord, and nerves. Now suppose, for example, that a man gets an attack of apoplexy, we find him paralytic—here is a lesion of the muscular function. We find him insensible to external stimulants, he feels no pain—here is a lesion of sensation. We may find his sight, hearing, taste, smell, and touch are injured. He lies in a state of insensibility, and is unconscious of every thing passing around him—here we have an example of interruption in the performance of the intellectual functions. All these phenomena exhibit the various lesions superinduced by an attack of apoplexy in the functions of those organs which subserve to the life of relation.

I have said that the term apoplexy is frequently abused in modern medicine. From the circumstance of most cases being accompanied by an effusion of blood on the surface, or into the substance of the brain, the term has been also applied to sanguineous effusions into other organs, and we hear every day of pulmonary and hepatic apoplexy; terms implying the extravasation of blood into the substance of the lung or liver. The analogy, however, in such cases will on examination be found to be coarse, and the application of the term loose and improper. Apoplexy, as a cerebral disease, may occur with or without effusion; in either case the disease, *quoad* the lesion of function, is the same; but to give the name of apoplexy to hæmorrhage into the lungs or liver is improper. The term apoplexy should be used only with reference to the brain, and applied to a particular train of lesions in the functions of the life of relation occurring *with or without an effusion of blood, or even congestion*. When we have effusions of blood into other viscera, we may have them unaccompanied by any apparent lesion in the functions of the organ affected (a circumstance rarely met with in the case of the brain,) and it would be much better to give some other name to those hæmorrhages into the substance of the liver and lungs, than to designate them by one drawn from a loose and imperfect analogy.

The suspension of the phenomena of the life of relation, complete or partial, which constitutes apoplexy, may be connected with any of the following pathological conditions. First, great congestion of the brain, in which the vascular system of that organ is overloaded but without extravasation of blood or serum; this is termed *the congestive apoplexy*. In the next place, we may have this congested state of the vessels of the brain with an extravasation of blood on its surface. To the latter form the *meningeal apoplexy* has been applied. Thirdly, with an effusion of blood into the substance of the brain, which is the most common case, and, lastly, we may have complete apoplexy without morbid appearance, or, if there be such, *quite insufficient to account for the phenomena*. A man will fall down suddenly, he will lie in a state of insensibility, with stertorous breathing, coma, and paralysis, he will die with all the symptoms of the worst form of apoplexy, and yet on dissection the brain may be found *to all appearance healthy*. This is what has been termed by the older authors the nervous or convulsive apoplexy, of the real nature of which we are still as ignorant as we are of the nature of tetanus, hydrophobia, and other nervous diseases unaccompanied by perceptible organic change.

This is the *simple apoplexy* of Dr. Abercrombie, of which he gives several most important cases, and refers to others related by the older authors. You will at once admit that it is not more extraordinary that apoplexy should exist without perceptible organic change, than mania, tetanus, hydrophobia, and other affections. Of the fact there is no doubt. Such cases indeed are rare, which in one sense may be looked on as a fortunate circumstance. But in the progress of other diseases, this nervous coma or apoplexy is by no means uncommon. Thus there is no symptom more common than coma in typhus, and yet if you examine the head after death, you generally either find no lesion at all, or such as will not be sufficient to account for the symptoms. The coma, which occurs in cases of painters' colic too, appears to be closely connected with this nervous apoplexy. You will recollect an interesting clinical experiment I made in the case of a patient with painters' colic who had profound coma. In this case I thought it probable that the condition of the brain bore no resemblance to sanguineous apoplexy, because the symptoms of painters' colic are seldom or never accompanied by hyperæmia of the nervous or other systems. Under this impression, I prescribed a full opiate, and this not only did not increase the coma, but, on the contrary, produced the very best effect, for the patient was amazingly improved the next morning. I do not so much mean to say, that opium is useful in nervous coma, as that in this instance, at least, the coma was not of the congestive kind. It is not unlikely, too, that the coma of jaundice is of the same description.

and unconnected with any decided hyperæmia of the brain. I am aware that in jaundice the coma is supposed by some to depend upon a bilious condition of the blood circulating in the brain, but there are so many cases of persons who have laboured under jaundice for years without having coma, that we must seek for some other explanation. Now, so far as we know of the encephalon in persons who have died of jaundice, it appears that little or no congestion exists, and hence it seems probable that the coma of jaundice is similar to that of nervous apoplexy.

I shall now proceed to the consideration of those forms of apoplexy which are connected with changes more or less apparent in the circulation of the head, and with which we are consequently better acquainted. I have told you that simple congestion of the brain may be accompanied by symptoms of apoplexy, or that we may have the disease presenting in addition to this an effusion of blood into the substance, or on the surface of the brain. The simplest idea you can get of the condition of the brain in the congestive form, is to consider what its state is in persons who have been hanged. These persons have the vessels of the brain loaded with blood from the violent interruption of the venous circulation. Now, this increase in the quantity of blood circulating in the brain, may arise from two causes, one depending on the interruption of the venous circulation, the other produced by an increased action of the arterial system. Hence in certain cases of disease of the heart, where the blood is sent with great force to the head, there is a strong predisposition to apoplectic attacks. The kind of disease of the heart, however, which has been found most liable to produce this, is not, as you would suppose, Corvisart's active aneurism, but simple hypertrophy of the heart, where the cavity of the left ventricle continuing the same, its walls are increased in thickness and strength, so that on the natural quantity of fluid an increased impulse is exercised. Such at least is the result of Andral's researches, and there is every reason to place confidence in the accuracy of his conclusion.

About this congestive apoplexy there appears to have been a good deal of misapprehension. You have all heard of *the serous apoplexy*. In this form it has been supposed that the cause of the compression of the brain and all the other symptoms is an effusion of serum, just as an effusion of serum into the cavity of the pleura will produce compression of the lung and dyspnoea. The idea which has been generally entertained is, that the effusion of serum is the cause of *all* the symptoms, and, in consequence, the same active treatment has not been adopted as in the other forms of apoplexy. This opinion will be best refuted by the investigations of Dr. Abercrombie, and I cannot do better than read for you the opinions of this eminent writer on the subject, as given in his celebrated and admirable work,

which I have no hesitation in saying constitutes one of the brightest ornaments of British medicine.

"The distinction, which has been proposed betwixt sanguineous and serous apoplexy, is not supported by observation. The former is said to be distinguished by flushing of the countenance and strong pulse, and by occurring to persons in the vigour of life; the latter by paleness of the countenance and weakness of the pulse, and by affecting the aged and infirm; and much importance has been attached to this distinction, upon the ground that the practice which is proper and necessary in the one case would be improper or injurious in the other. I submit that this distinction is not founded upon observation, for, in point of fact, it will be found that many of the cases, which terminate by serous effusion, exhibit in their early stages all the symptoms which have been assigned to the sanguineous apoplexy; while many of the cases, which are accompanied by paleness of the countenance and feebleness of the pulse, will be found to be purely sanguineous; and one modification of the disease in particular will be described, in which these symptoms are very strikingly exhibited, while the disease is found to be sanguineous apoplexy in its most hopeless form.

"Portal has described a series of cases which afford the same result; of three, which presented all the symptoms of serous apoplexy, one was saved by repeated bleeding, and in the other two, which were fatal, there was found extensive extravasation of blood. Case XCVI., lately described, forms a remarkable addition to these observations. If any case could be confidently considered as serous apoplexy, this was such. Dropsical effusion had existed in the body for months, and in defiance of every remedy it had been progressively gaining ground. There were symptoms indicating its existence, both in the thorax and in the abdomen; the patient then became comatose with pale countenance, and died; but though dropsy was found in the other cavities none could be detected in the brain.

"In other parts of the body serous effusion is very seldom a primary disease; it arises as a result either of inflammatory action, or of impeded circulation, and takes place slowly, not accumulating at once in such quantity as to induce urgent symptoms. It is therefore in the highest degree improbable, that it should occur in the brain as a primary disease, and accumulate with such rapidity as to produce the symptoms of an apoplectic attack.

"The quantity of fluid effused bears no proportion to the degree of the apoplectic symptoms. We find it in small quantity though the apoplectic symptoms had been strongly marked and long continued; we find it in large quantity when the symptoms have been slight; and, finally, we find most extensive effusion in the brain where there have been no apoplectic symptoms at all. The direct

inference from these facts is, that, in the cases of apoplexy with effusion, the presence of the fluid cannot be considered as the cause of the apoplectic symptoms."

The same error has been committed with respect to hydrothorax, a disease almost never primary, but the result of either pleuritic inflammation, obstruction of the heart or lungs, or some analogous cause. The cause of the symptoms is not the mere effusion of fluid, but some pre-existing disease which has given rise to a serous effusion. In Dr. Abercrombie's work you will find the remarkable fact stated, that there may be a copious effusion of serum in the head without producing apoplectic symptoms. The following case, mentioned by Dr. Abercrombie, furnishes a remarkable illustration:—A patient, who had laboured under hypochondriasis for upwards of thirty years, began to decline rapidly in health. He was extremely feeble, his bowels costive, his sleep disturbed, and his appetite gone. This state continued for some time, and he began to sink, but he never complained of headach, giddiness, convulsions, or paralysis, and his mental powers remained unimpaired until a very short time before death. Yet, on opening the head, there was an exceedingly copious effusion of serum found under the arachnoid, and in some places this was so great as to give the arachnoid the appearance of small bladders filled with water. The ventricles were distended with fluid. Dr. Abercrombie gives another case, where the quantity amounted to eight ounces, and notices a case, mentioned by Dr. Marshall, of a maniac who died of mortification of the feet; a few hours before death he became perfectly rational, yet effusion was found both on the surface of the brain and in the ventricles, amounting to more than a pound.

All these facts go to prove, that what has been termed serous apoplexy is only an apoplectic attack depending on congestion of the brain, that in some cases we may have this congestion accompanied by serous effusion, in others not; that the effusion is secondary and by no means of constant occurrence, and that altering our practice and pursuing a less active plan of treatment in such cases would be improper. The same treatment should be adopted in the serous as in the congestive form of the disease, for where the nature of the affection is the same the same curative means should be employed. Why it is that effusion takes place in one case and not in another we cannot tell; such changes are connected with laws of organisation, of which we are present ignorant. We know as little why this should occur as why inflammation of the liver in one case is followed by enlargement, in another by the secretion of pus, in a third by cancer, or in a fourth by hydatids.

We now come to the consideration of apoplexy with extravasation of blood. This is the form of the disease to which the term apoplexy has been restricted by one of the last

writers on the subject, M. Rochoux. In this affection the extravasation of blood, which constitutes the principal pathological feature of the disease, is found to exhibit a remarkable variety as to its seat and extent. In some cases the blood is effused on the surface of the brain, in others into its substance, and in a few cases into the ventricles. De Haen gives some cases of apoplexy produced by rupture of the choroid plexus, but in the great majority of cases, where blood is found in the ventricles, the extravasation has taken place in one hemisphere, and, tearing through the substance of the brain, has made its way into their cavities. Of the three varieties of apoplectic effusions the ventricular is the rarest; the next to this is the meningeal, or that in which blood is poured out on the surface of the brain, and the most common is where it is effused into the substance. It has been also found that certain parts of the brain are much more liable to sanguineous effusions than others; of the reason of this, as of many other phenomena connected with the circulation of the brain, we are still in ignorance. The following table, which you should bear in mind, exhibits a remarkable preponderance in the liability to sanguineous effusions of certain parts of the brain. It has been taken from the *Precis d'Anatomie Pathologique* of Andral. The following is a summary of the results of 386 cases of apoplexy.

In 202 cases, the effusion took place into the substance of the hemispheres of the brain, in that part which is on a level with the corpora striata and optic thalami. The portions of the brain next most liable to effusions are the corpora striata; and here we have 61 cases. Next to this are the optic thalami, in which we have 35 cases. In that portion of the hemispheres above the centrum ovale, 27 cases. Lateral lobes of the cerebellum, a proportion of 16 cases. In those portions of the brain anterior to the corpus striatum, 10 cases. In the mesocephalon, 9. Spinal cord, 8. Posterior lobes of the brain, 7. Middle lobe of the cerebellum, 5. Peduncles of the brain, 3. Olivary bodies, peduncles of the cerebellum, and pituitary gland, 1 in each, making 3.—Total 386. Out of these, we find 325 cases occurring in the hemispheres of the brain, corpus striatum, and optic thalamus.

In the number and size of these effusions we find the greatest varieties. In some cases an enormous effusion takes place, and many ounces are extravasated into the substance of the brain; in others, the quantity is trifling, being sometimes as small as a pea, or even less. It has been observed that in cases where numerous extravasations were discovered, they were generally found to be in different states, as if they had occurred at intervals, and not simultaneously. This leads us to the knowledge of one of the most important facts in pathology, that in many cases of apoplexy, after a clot has been formed, nature commences at an early period a process of

cure. The change, which takes place in cases where a patient recovers, seems to be the following:—It becomes at first somewhat gelatinous, it is next observed to be more consistent, and it loses its red colour, and takes on a whitish or yellow appearance. The clot is gradually removed, and along with the absorption of the clot there is a process of isolation going on. A fine membranous cyst, furnished with vessels, is formed round the clot. In some cases the clot is replaced by a quantity of serous or gelatinous fluid; but in the majority of instances this does not occur, and the cyst has been found empty. This is a fact which has been established by numerous observations.

There is the greatest possible difference as to the period at which the absorption of the clot is completed; but we may safely assert, from the number of cases in which, after paralysis, a recovery takes place, that this process is of very common occurrence. In several cases, where apoplexy followed by paralysis has happened several times during the lifetime of the patient, a number of those cysts, corresponding with the number of attacks, and presenting various appearances according to the date of their formation, have been found. It appears then that the cure of apoplexy depends solely on the absorption of the clot; and that, as long as this remains unabsorbed, the patient is in danger. In some cases absorption does not take place at all, the clot becomes organised; and in this way it is supposed that some of the tumours found in the brain are formed. There are several circumstances which favour the absorption of the clot, but nothing so powerfully as a healthy condition of the whole cerebral circulation. This leads us to the consideration of the importance of paying attention to the head long after an attack of apoplexy. It inculcates the necessity of avoiding every thing calculated to add to the existing congestion, and shows that, in the paralytic or after-stage of an apoplectic attack, we should not neglect to deplete the head from time to time. The great point is to keep the head perfectly free from irritation; for it has been found, that, where a cure appeared to be going on, any new irritation applied to the brain has had the effect of arresting the absorption of the clot, and marring the process of cure.

I regret I cannot dwell longer on this subject, as I wish to conclude the pathology of apoplexy to-day. There are, however, two more observations to be made before I close the subject. The source of an apoplectic effusion is very hard to be discovered: it appears generally to come from a number of minute vessels, for we are seldom or never able to trace it to the rupture of a vessel of any size. The age at which persons are most subject to apoplexy appears to be from fifty to seventy. You should, however, be aware that apoplexy with sanguineous effusion is by no means uncommon, even in persons of a tender

age. Billard details an instance of this in a child soon after birth. There are also several cases mentioned as occurring in children during the first three or four years. Andral gives the case of a boy of nine years of age, who died of apoplexy, with a vast effusion of blood. One of the most remarkable cases of this kind I ever witnessed, occurred in a child who had been just weaned. This child had been labouring for some time under symptoms resembling incipient hydrocephalus, and then suddenly got an attack of convulsions, followed by coma and paralysis of one side. From a careful study of the symptoms, I ventured to make the diagnosis of apoplectic effusion, and on examining the brain after death there were nearly three ounces of blood found effused in the base of the brain.

I shall resume this subject, gentlemen, at our next meeting.

ON THE RESTORATION OF THE PERINÆUM, IN CASES OF ITS DIVISION OR COMPLETE LACERATION IN THE FEMALE.

*Read before the Académie des Sciences,
January 6, 1834.*

BY BARON ROUX.

GENTLEMEN,—Rupture of the perinæum is most commonly owing to the effect of a badly managed parturition, which frequently takes place in the first labour, and also from an unmethodical application of the forceps. Other circumstances also occasion its complete or incomplete destruction; such as an accidental wound, though the region occupied by the external organs of generation in the female, and the surrounding parts, are but little exposed to injury from external violence. Gangrenous ulceration, or gangrene properly so called, such as is developed in other parts, can produce likewise this accident. Can it not also proceed from a voluntary, criminal, or maniacal action? I have some recollection, though I cannot exactly remember where, this fact has been recorded, that in one instance this mutilation was the result of an atrocious vengeance exercised by a husband on his wife, whom he knew to be faithless. Even art itself may occasion, in certain cases, a similar affection. In one female, of whom I shall speak more particularly hereafter, a most complete division of the perinæum succeeded to an operation undertaken, ineffectually, to cure a simple fistula.

The congenital division of this part is not comprised in this etiological review. In fact, there is not a single case known, I believe, where the external parts of generation in the female, and the anus, were confounded by a primordial disposition. The perinæum appears to escape this vice of conformation, which so frequently occurs in other points of the

median line, as in the superior lips, velum palati, sternum, linea alba, &c., &c.

In whatever way the laceration of the perinæum is produced (I comprise the recto-vaginal septum in this region), it has not always the same appearance or the same extent. It is a very remarkable circumstance, that sometimes the recto-vaginal partition is alone ruptured, and nature occasionally effects the cure; but, in general, the perinæum remains affected. There sometimes exists an extensive perforation or central laceration, through which the entire infant has been seen to pass; in this case, also, it suffices to allow nature to take her course in the re-union of the divided parts. At other times there occurs a more or less extensive rupture of the anterior portion of the perinæum, the anus and its sphincter retaining their integrity. This case, though it appears less serious than the preceding, is, however, much more so in reality. In fact, the re-union produced by nature is always imperfect, and the inconvenience remains, especially in young females, the vulva remaining very far prolonged posteriorly, and deprived of all contractility. There exists, at other times, a rupture of the entire perinæum—a complete laceration of this part—which may extend through a portion of the recto-vaginal partition. I shall conclude with this case, which is incontestably the most severe of all.

In truth, a re-union produced by the resources of nature alone has never been observed: in every case the edges of the wound cicatrise separately, consequently the perinæum entirely disappears; the vulva and the anus form only one canal, one common slit, a deep sinus presenting margins either smooth or irregularly indurated, and lined by a mucous tissue. If this division extend slightly into the recto-vaginal septum, the inferior part of the rectum and vagina form a true cloaca.

The condition of a female in this state is truly deplorable; it is not that she cannot any longer conceive, and even be delivered more easily than another. A lady, of whom I shall speak hereafter, labouring under a complete laceration of the perinæum, gave birth to a second child a short time before I had recourse to the suture. I knew an English lady who had experienced the same accident at the time of her first accouchement, and who had subsequently become the mother of twelve children. I am sure that a great number of similar cases exist, but perhaps by dint of dexterity, and various means of deception, with which I am unacquainted, females succeed in concealing an infirmity so adapted to inspire disgust.

For the partial loss of their natural charms is not alone concerned in this instance: an inconvenience as frightful as an artificial anus is subjoined. The sphincter of the anus being lacerated nothing can oppose the escape of the intestinal gases through the rectum, and the continual, or at least frequently repeated and

almost involuntary exit of fecal matter. The latter may, however, sojourn for a long time in the rectum, if it possess a certain degree of consistence; but if liquid, the desire to evacuate is excited, it escapes involuntarily, and deluges the vagina and surrounding parts. Hence the patient is compelled to live in a state of solitude unnatural to her age, sex, and accustomed habits. She sinks into a state of profound grief; her health is almost invariably impaired; and her complexion loses its fresh and blooming appearance.

The honour of the first attempt at remedying this infirmity is due to French surgery. Guillemeau, pupil, rival, and contemporary of Ambrose Paré, recorded the first facts relative to the suture of the perinæum. He employed the interrupted suture, and the operation succeeded. Independent of the great confidence which this celebrated surgeon inspires, the circumstances which accompany the relation of this case are calculated to guarantee its authenticity. I cannot say so much for another example of success, attributed to an obscure surgeon, and noticed in the *Ephémérides des Curieux de la Nature*, a publication which has not always possessed a sufficient reputation for truth.

At a later period Mauriceau, Lamotte, and Smellie appear to have thought it possible to undertake the restoration of the perinæum, and recommend the uninterrupted suture to be adopted for this purpose, but without saying whether they had ever employed it themselves. The operation remained a long time afterwards in oblivion; but, towards the close of the last century, two French surgeons, MM. Noel de Rheims et Saucerotte de Lunéville, performed it on two separate patients, and succeeded by employing the twisted suture. These two facts constitute an epoch in science, and during a long time they were alone known, alone quoted, and formed the sole base of the brief considerations to be found in our classic works on the restoration of the perinæum.

The celebrated surgeon, who was my preceptor before I was connected to his family by matrimonial ties, and of whom death has recently deprived the Academy, had never, in the course of his long career, performed the suture of the perinæum, and limits himself, in his excellent work on surgery, to the non-disapproval of the trials which may hereafter be attempted. His cotemporary in age, and his equal in renown, M. Dubois, has performed it in one case, but without success. M. Paul Dubois, his son, has attempted it once also at the Hôpital de la Maternité, and the result was equally unfavourable. Both followed the method of Noel and Saucerotte; after that my numerous cases of success had recalled the attention of the medical public to this subject, mention has been made of a cure, performed by M. Dupuytren, twelve or fifteen years since, to which he attached but little importance.

The *Revue Médicale* also relates a case of suture of the perinæum, performed at about the same time, with an equally favourable termination, by M. Montain, junior, one of the most expert surgeons at Lyons. I must confess that a part of this operation resembles the method, the first idea of which I thought to have belonged exclusively to myself, since it is only lately that I have become acquainted with this fact. English surgery, so eminent in many respects, has proved completely sterile on this subject. Since the commencement of the present century some German practitioners have attempted the revival of the perineal suture, and have published elaborate discussions on the period, the most opportune for the performance of this operation. Mursinna, Mentzel, Osiander, and more especially Dieffenbach, of Berlin, have paid particular attention to this subject, some of whom have proposed the uninterrupted and interrupted suture, and others the twisted, but none of these distinguished writers has ever suggested the employment of the quilled suture. According to Dieffenbach, there exists but little chance of success without making two parallel incisions on the sides of the vulva and perinæum; thus preventing the traction and the too forcible extension of the parts to be embraced by the threads, or transfixed by the needles. This method was adopted by the celebrated surgeon of Berlin, but his efforts were only twice crowned with success. Osiander, however, obtained a propitious result, without having recourse to the lateral incisions.

The recent attempt of the German surgeons were known, and the success obtained by them was universally admitted, but not however without credulity; these cases being regarded as exceptions.

It was considered impossible, in France especially, to discover a method applicable to every case, in which the restoration of the perinæum was required, and presenting sufficient probabilities of success, even when performed by the most expert practitioner;—this operation then was abandoned as being, if not too difficult in its execution, at least too uncertain and hazardous in its results. I myself, four years since, even participated in this general prejudice, until the following case was presented to my notice, which changed my ideas, and will signalise, I am convinced, a beneficial progress in surgery, and the first consolidated step towards permanent conquest.

CASE I.—A young lady, from Normandy, came to Paris in the month of December, 1831; she was 22 years of age, and married at 19 to a medical man residing at Valognes; impregnation having almost immediately succeeded this epoch, delivery ensued when she had scarcely attained her twentieth year. The parturition having been laborious, recourse was had to the forceps, which produced a complete laceration of the perinæum, which was

prolonged nearly half an inch into the recto-vaginal septum. Nature had done nothing towards the reparation of this accident when the patient presented herself to me, two years from the period of her misfortune. I found, on examination, that the laceration followed precisely the median line, its edges were completely cicatrised, but supple, flexible, and unindurated, or without the slightest degree of callus, so that congenital division might have been suspected, the anus and the vulva forming only one and the same aperture, and it was necessary to separate the edges, in order to perceive the limits of the recto-vaginal partition.

All the inconveniences before enumerated existed in the highest degree, and the patient had fallen into the most profound melancholy. In order to render the necessity of going to the water-closet less frequent, or to avoid the involuntary escape of fecal matter, she had been accustomed to have recourse to the preparations of opium, whose astringent properties she experienced in a most remarkable degree, and which procured at pleasure a more or less protracted constipation.

Notwithstanding this artificial command over the intestinal action, she had judiciously reduced her meals to the quantity absolutely necessary for the support of life; and, from fear of being surprised by a sudden and imperious escape of flatulent or fecal matter, she lived in comparative seclusion from the world.

Yielding to the earnest intreaties of her husband, I consented to hazard an operation, which was only known to me by the observations of Noël and Saucerotte, with the exception of the more recent attempt of Dieffenbach. I had no hopes of success. Nevertheless, the regular aspect presented by the solution of continuity, the ardent desire which the patient manifested to be emancipated from her pitiable condition, the patience and courage which she felt capable of sustaining, her age, the perfect health she enjoyed in spite of the melancholy; and, although her *embonpoint* was in some measure lessened, every thing seemed to concur in authorising this undertaking.

I ought also to have considered as a favourable circumstance, the facility required of supporting, during a long time, a rigid diet, and of procuring, by means of opium, a greater or less prolonged constipation. Hence, in fact, I had reason to hope the suspension of alvine dejections for the time necessary to the consolidation of the perinæum, and the removal of the greatest obstacle opposed to the success of the operation.

The operation was first performed in the month of January 1832; and, as I did not possess any experience as regards the laceration of the perinæum I thought it advisable to pursue the plan already traced. For this purpose, I constructed several long and strong silver needles, terminated by an immoveable steel point. I commenced by removing from either side an extremely thin portion, which

was nearly quadrilateral, and from an inch and a half to about two inches in length, taking care to encroach slightly on the skin and parietes of the vagina, and sufficiently to prolong the flaps of the anus towards the external labia, so as to render the vulva rather a little too narrow than too wide after the suture was made, and the operation finished; I wished to approximate as extensive surfaces as possible, and thus increase the chances of success.

In the second place, I incised separately the two margins of the small cleft which extended into the recto-vaginal septum, and included them in a common suture. This being done, I proceeded to apply the twisted suture on the external soft parts or perinæum. Four needles which penetrated the whole thickness of this part, even as far as the parietes of the vagina, were successively introduced at about half an inch from each other, and the points of entrance and exit were distant an inch from each margin. The stricture exercised by the threads was moderated; and, although the parts of the perinæum which remained exposed appeared slightly stretched, there was no reason to fear the laceration of the portions embraced by the needles. I therefore dispensed with, and it was really useless to make the lateral incisions so greatly recommended by Dieffenbach. I afterwards applied several pieces of linen to preserve the skin from any painful pressure, after which I sought the means of retaining the thighs in exact approximation, and to prevent their involuntary separation during sleep. The most judicious attentions were bestowed on the patient by her husband, an able medical practitioner; and, at the commencement, every thing went on favourably, not the slightest untoward symptom supervened, the inflammation, as far as could be judged, was developed to a suitable degree, the patient complained only of slight pain in the vicinity of the wound itself; a catheter was introduced every time the necessity of urinating was experienced, and a severe abstinence from aliment sufficed to arrest the alvine evacuations, which were only re-established after the complete union of the parts.

Six days having elapsed since the operation, I determined on extracting the needles, and withdrawing the thread. You might have supposed, that at this epoch reunion was effected; the two parts of the perinæum were retained in immediate contact, but this reunion was only apparent, being maintained by a glutinous substance. Two days afterwards it was broken through, and the parts resumed their primitive aspects.

In spite of this unfortunate result, it was decided to renew the attempt. The condition of the parts was absolutely the same as before the operation, since the paring of the margins having produced so trifling a loss of substance, it ought not to be brought into account. The patient was, however, debilitated from lying

in bed, from abstinence, and from the grief occasioned by the want of success; in addition to which, it was in the middle of winter, and hence the necessity of retarding the operation. Lastly, the arrival of the cholera added to this delay, so that the operation could not be performed until the month of May.

I had deliberately reflected on the circumstances which produced a failure in the first instance, and was convinced that I ought to attribute it to the form of suture which I employed. The twisted suture, acting with all its force, exerts its influence only on the superficies, and is unable to produce an exact approximation of the deep seated parts. Thus the wound remaining open towards the vagina, its internal edges were continually moistened with mucosities, which flow in greater abundance from this canal since it participates in the perinæal inflammation. This idea induced me to reflect, if the quilled suture would not be preferable, and I ultimately decided on its employment. I pared the cicatrised parts as in the first operation, and applied four ligatures, causing the curved needles which conducted the thread to act on the one side from without to within, and on the other from within to without. I took care to encroach a little on the parietes of the vagina, sufficient only, however, to make a slight traction on them, so as to enable me to approximate the two wounds throughout their whole extent. The ligatures being introduced, I employed as cylinders two moderately strong pieces of an elastic gum catheter, one of which was placed in the loops which the double threads formed on one side, and on the other between their separate ends, and finished by making with the latter, in the first place, a very strong single knot, and afterwards a bow upon the second cylinder. I did not fear to press the edges of the wound rather firmly together. I must not forget to mention, that, from the manner in which the quilled suture acts, it produces an eversion of the edges of the wound, and thus the adaptation is never so perfect externally as might be desired; but I had previously thought of the means best adapted to prevent this effect, and to bring the skin in contact with itself. I succeeded, by the aid of small ligatures, introduced at different points between the principal sutures, and which served as so many stitches of the common suture, being, however, but slightly drawn together. I had foreseen, calculated, and so well devised every thing before hand, all went on as well as I could desire, and I have performed few operations in surgery which have given me so much satisfaction in their execution. The suture being terminated, the parts were not more stretched than after the first operation, and I therefore dispensed with making the lateral incisions recommended by M. Dieffenbach. The same attentions were bestowed on the patient as after the first operation. I did nothing to provoke evacuations, hoping to be aided by the habitual

constipation, which, in fact, persisted until the twenty-second day.

At the commencement of the seventh day I removed the cylinders, and withdrew the ligatures; at this epoch the perinæum presented an appearance of reunion, differing altogether from simple agglutination; its two sides were already united, and would have required a certain effort to separate them. The cicatrix insensibly acquired force and solidity, and in a short time the consolidation of the perinæum was perfect. The first evacuation took place on the twenty-second day, at which time the anus was rather too narrow than too wide, and the expulsion of the fecal matter, which formed a rather considerable mass, and of great consistence, was not accomplished without difficulty, and it was even necessary to assist nature by pressure exercised from above downwards by means of the finger introduced into the vagina. But the union was at this epoch so intimate and solid, that a defection still more laborious would not have caused its rupture.

The perinæum thus reunited did not differ in any respect from a perinæum in its natural state, especially in a female whose sexual organs have not as yet been exercised. It was two inches in length, and divided by a lineal raphe in two symmetrical halves; on examining it either by the vagina or anus, it felt thick, solid, and even vigorously constituted. This state of the parts was attested in my presence by the celebrated accoucheur M. Deneux. This lady left Paris towards the latter end of June. There still existed at this time in the recto-vaginal septum, immediately above the perinæum, a very small opening, communicating with the rectum and vagina, which allowed only the occasional escape of gas, the passage of fecal matter being altogether impossible; since this, however, it has become completely closed.

From this time I permitted the female and her husband to resume their conjugal habits, and at first some difficulty presented itself, arising from the narrowness of the vulva. I would rather have wished that this young person had not again exposed herself to pregnancy, at least so soon after the operation. I was even inclined to desire on her account, that she would never return to this condition; this, however, was not the case, she conceived at the termination of the same year, and has now been confined three months. The accouchement was favourable, and terminated naturally, after a few hours' suffering, and although the perinæum was exposed during a considerable time to the effects of an active parturition, it did not experience any laceration, either complete or incomplete, not even the slightest traction.

It is easy to conceive the advantages afforded by the quilled suture over all others, especially when twisted. As it is with curved needles that the thread is introduced, you can cut more deeply, and embrace with the liga-

tures (which ought to be very strong) more of the parts than with the straight needles; the threads, although stretched from the tension to which they are submitted, do not assume a degree of tension, or especially a rigidity similar to those applied by the straight ones. Hence the prompt division of the parts, with which they are in immediate contact, is less to be feared, and moreover the cylinders exercise on the whole length of the margin of the wound an equal and uniform compression. The result is a more perfect adaptation, which acts as much and even more on the deep-seated than on the superficial parts, so that all passage of fluids between the approximated surfaces is rendered impossible. In addition there neither exists torsion nor constriction of the edges of the wound, and these are only attracted through the medium of distant parts, pressed one against the other, and altogether free externally, there is less susceptibility of being cut or lacerated by the sutures, which it may be necessary to leave for a time, more or less long. Such were the reasons that induced me to employ this suture, and the event has fully confirmed my choice.

A fact so complete, and so decisive as much in favour of the suture of the perinæum, as of the method I followed, was naturally attended with publicity. In fact, four cases of chronic laceration of this part have presented themselves to my notice this year, and on which I operated after the same manner, three of these were cured. I should abuse the attention, which the Society of the Academy so readily grants me, were I to give to their history the extent that my first observation required, it will suffice to indicate the circumstances peculiar to each.

CASE II.—The subject of the first was a young girl, 21 years of age, who became a mother at 19; her delivery was effected by the sole efforts of nature, but produced a complete rupture of the perinæum; she was named Josephine Erard, and was discharged from the venereal hospital, where she had undergone an anti-syphilitic treatment, when I received her into my ward at the Hôpital de la Charité at the commencement of March, 1833. Before the operation it was only necessary, for the space of a few days, to put her on moderate diet, to retard, as much as possible, the necessity of alvine evacuations. The operation was publicly performed before numerous students and practitioners. The method was exactly the same as that employed in the case of the young lady residing at Valognes; but I did not rely on the beneficial influence of a constipation, prolonged until the entire consolidation of the parts. On the evening previous to the removal of the ligatures, which was the sixth after the operation, I solicited liquid evacuations by the administration of a laxative. The same precaution was frequently renewed at appropriate intervals. Three weeks sufficed to produce the perfect restoration of the vulva.

and anus to their natural condition. A small aperture, occupying the most deep-seated part of the recto-vaginal partition, and which allowed a partial passage to the intestinal gases from the rectum into the vagina, persisted a few days, but it was reduced to the smallest dimensions when the patient quitted the hospital about the termination of the month of May.

I have since learnt that this girl promptly yielded to her *penchant* for the life of a concubine, to the risk of becoming pregnant. In truth, I fear less on her account the hazard and perils of a renewed accouchement, since I have been encouraged by the safe delivery of my patient at Valognes. As to the precautions which I have taken in all my other operations, of diluting the excrement by the means of laxatives, I lay it down as an important rule of practice for the assurance of success.

CASE III.—In October last I received into the Hôpital de la Charité Madame Claye from the environs of Compiègne, aged 29, who was sent to me by M. Donné. This female from the age of 18 had been delivered four times safely, and at the usual period, and it was not until her fifth accouchement (which is rather remarkable) that the application of the forceps was required, and a rupture of the perinæum occurred, which was as complete as any of those which I have as yet observed, and likewise included a small portion of the recto-vaginal partition. M. Jacobson of Copenhagen was then in Paris, and I was able to render him witness of the operation, and before his departure this celebrated surgeon had thus an opportunity of appreciating this newly-invented method. It was difficult to see a more perfect restoration of the anus, vulva, and perinæum to their natural condition, than that which occurred in this female, who was visited by a number of Parisian practitioners, and especially accoucheurs.

CASE IV.—My last case of success was in that of a lady, whose name and rank in society I am obliged to conceal, who, until the moment that I saw her, had carefully concealed her horrible infirmity. M. Maygrier, having delivered her only three months before the operation, was alone confided with the nature of the accident, which had already been of two years' date. I performed the operation the last month, with the assistance of two of my dressers and M. Maygrier; although this lady had arrived to her thirty-fifth year, the success was as complete as in the preceding cases. An event might have deceived our hopes, for a short time after the operation, this lady lost her last born infant, which caused her excessive grief. But the stitches had been already removed, the parts had contracted a certain degree of union, and in spite of the disturbances supervened in the whole economy, the ulterior consolidation of the parts was not retarded.

The only reverse, which I have experienced in performing this suture, is of recent date, in an operation of this description performed at the latter part of last December, since in this case the woman died.

CASE V.—The female was forty years of age, the destruction of the perinæum was of eighteen months' standing, and not the result of a laborious accouchement, but of an operation performed in order to cure a fistula in ano, communicating, without doubt, with the rectum at the inferior part of the vagina. In addition to the general and unfortunate results of the division of the entire perinæum, there was a complete prolapsus of the rectum. On standing, however short a time, and especially if in this position she coughed, sneezed, or laughed, the intestine protruded through the enormous cleft in this part, and formed externally a tumour as voluminous as the fist, which was with difficulty reduced, and reappeared almost instantaneously. Lastly, when this female entered my ward, which was about the middle of the month of November, she suffered greatly from simple continued fever, accompanied with violent diarrhoea, and she complained of an uneasiness of the abdomen; all these symptoms denoted latent inflammation of the intestinal tube, evidently owing to the frequent exposure to the air of an extensive portion of the mucous membrane of the rectum.

I was obliged, in the first place, to consider the most suitable means of removing this complication, although the operation appeared, and was in fact, more indispensable in this than in any of the other cases. During three or four weeks the patient was submitted to repose, to an appropriate diet, and to every thing which could moderate the irritation of the intestines and the profuse evacuations; at length, her position being wonderfully ameliorated, I yielded to her entreaties, and performed the operation; but, from the third day, a considerable diarrhoea came on, and fever supervened. The abdomen now became painful to the touch, and the patient lost her strength and energy. As regards the wound, the parts included between the sutures did not experience that tumefaction, that inflammatory swelling, that brisk, healthy, and legitimate determination, which prepare the immediate adhesion: they were, on the contrary, sensibly diminished. The ligatures themselves were ulcerated, and those which communicated with the interior of the rectum allowed the escape of a small quantity of liquid faecal matter. At the commencement of the seventh day I removed the cylinders, and withdrew the threads. There appeared to exist an incipient union; the edges of the wound were slightly glued together, but the next morning their disunion was complete, and two days afterwards the patient expired.

In this case, the operation presented this particularity, that, on account of the enlarge-

ment, which the repeated prolapsus of the rectum had caused the parts to experience, I was obliged to make four stitches, whilst three had sufficed in the preceding operations, and ought to suffice in the majority of cases. These points of suture ought to act, and have acted as much, or even more, on the intestines than on the vagina, a circumstance which might have occurred in the prompt return and rapid progress of these symptoms which caused the death of the patient. Perhaps, also, I did not retard the operation a sufficient length of time; influenced no doubt by the hope and desire to witness promptly another success added to those which I had already obtained. It was, moreover, the most disadvantageous case which could be encountered; and although success was not altogether improbable, it would have been more remarkable than in the preceding; a diseased state, very unpropitious in itself, complicated the deformity, and it was the rapid progress of this complication which caused the death of the patient much more than the operation itself.

It has been seen, that in all these cases a complete division of the perinæum had taken place, the borders of which were for a long time cicatrised; and it is probable that it will be always necessary to restore this part under these circumstances, rather than in recent lacerations, as these are not always detected in the first instance, and the others are frequently susceptible of a spontaneous cure. It is certain that those cases where nature should be deemed important, when the solution of continuity is recent, are not adapted to the operation. This is at least true in the majority of instances, and particularly in those where a complete laceration is the result of laborious parturition. In fact, the recently ruptured parts have experienced the greatest violence; they have been submitted to an extraordinary distension, and are about to be seized in a short time with considerable tumefaction. The slightest cause is sufficient to produce the most violent inflammation, which may assume a very unfavourable character; they will also shortly afterwards be deluged with the lochia, and it would be doubtless more difficult to return the edges of the wound in exact apposition, and prevent them from being moistened by the fluids, which must necessarily flow in abundance from the vagina; doubtless every case is not favourable to the success of the perinæal suture, and moreover is the treatment, which ought to follow the operation, compatible with that which the nature of the diseases succeeding an accouchement may require? besides, would it be prudent to submit, to a protracted and painful operation, a female lately delivered, a being become momentarily so nervous, so susceptible of impressions, in whom the slightest emotions might cause the most untoward consequences, and to whom it would be necessary to explain a misfortune, of the nature of which she is entirely ignorant, without being able to

promise the efficacy of the means employed in its remedium?—Assuredly not; it is better to procrastinate and postpone the attempts of cure to a time when the health of the female is re-established, the edges of the wound covered by a cicatrix, and the surrounding parts restored to their natural condition.

Were it only to prepare the materials for a more perfect account of the restoration of the perinæum, an operation which will become, I make not the slightest doubt, familiar to surgery, I would not forget to mention certain circumstances, which occurred in all those cases where I have performed it. Inflammation supervened in the parts themselves, only to a degree strictly necessary to produce their re-union; it never assumed a serious character, and no untoward symptom of any description ever declared itself. Nevertheless it is right to bear in mind that the vagina is always attacked with a purulent discharge in comparative abundance. I moderated its effects, and prevented the stagnation of the mucosities, by frequently repeated injections of emollients. It is a circumstance rather remarkable, that in every case either by the exact approximation of the thighs, or, what is more likely, on account of the discharge being distended over the whole of the vulva, and from the swelling of the parts surrounding the meatus urinarius, or of this aperture itself, there existed during many days an impossibility to urinate, and it was necessary to have recourse to catheterism.

Perhaps it would be right to adopt, as a general rule of practice, to place a catheter permanently in the bladder, or to introduce it at suitable intervals during the first few days, even when retention of urine does not exist, in order to prevent the flow of this fluid on the inflamed parts.

In every case, also, after the removal of the sutures, and a short time before the consolidation ought to have been accomplished, the edges of the division were disunited, or rather separated, in the vicinity of the anus, at which point the wound was slightly gaping, and there existed a small slit, similar to that which might have resulted from the operation of fistula in ano. But this little cleft constantly disappeared, and the anus, into which I took care to place a small mesh besmeared with cerate, resumed promptly its natural disposition.

Lastly, in spite of the care which I constantly took to pare the little margins of the spur-like process of the recto-vaginal septum, which I traversed with a ligature in order to effect its approximation of the parts belonging to the perinæum, properly so called, it required a sufficiently long time to obstruct all communication between the rectum and vagina.

Intestinal gases and faecal matter (only, in fact, when liquid) always escaped through the vagina; and this took place even when the perinæum was firmly consolidated; but

the aperture in the septum insensibly contracted, and terminated either by total abolition, or by becoming so narrow, that it allowed occasional passage only to a small quantity of gas.

These, gentlemen, were the important facts which I had to communicate to the Academy. Four times in less than eighteen months, and in three instances during the year which has just elapsed, I succeeded by this method in re-establishing the lacerated perinæum, thus rendering to four females the attributes of their sex. It was a simple, but, perhaps, I may be permitted to say, a happy idea which conducted me to its adoption. I am free to confess, that I have invented, that I have conceived—nothing: I have only applied a method already known, having submitted it, however, to some modifications, which the situation of the parts required. I make no doubt but that, in a short time, the same thing will occur in the suture of the perinæum as in the staphyloraphia, an operation which did not exist in surgery fifteen years since, which I imagined and performed for the first time in 1819, which has since been adopted by every surgeon, and which, a few weeks ago, I again performed for the sixty-fifth time.

Foreign Medicine.

SOCIÉTÉ ANATOMIQUE.

Ramollissement of the Bones in a Subject attacked with Syphilis.

CASE I.—A woman, treated for paraplegia, died with a gangrenous eschar on the sacrum. On the post mortem examination the neck of each femur was found completely destroyed, (the head of the bones resting on the great trochanters;) all the bones were softened, and on the least effort became fractured, on the evening of her death, fracture of the thigh-bone occurred; the whole of them were as cartilage, and easily divided by the scalpel. The osseous tissue, as well as the medullary membrane, were extremely vascular; the marrow of the bones was soft, pulpy, and reddish; some syphilitic vegetations existed in the vagina. There was not the least trace of cancerous deposition; the body was not emaciated.

CASE II.—*Varicose Aneurism—Amputation.*—A patient, who was bled, became affected with varicose aneurism at the bend of the arm. A ligature was applied above the tumour, which disappeared, but still there remained aneurismal varicozes of the fore-arm.

A year afterwards M. Roux thought it necessary to perform a second operation, but the ligature, which he had desired to place below the point of communication with the artery and vein, was applied above, and compressed the median nerve. In consequence of a consecutive hæmorrhage, from a third attempt at an operation, amputation became necessary. The amputated portion showed a communication established between the brachial artery, near its termination, and the deep veins of the fore arm. As to the median basilic, the vein that was opened, no trace of it on the divided limb could be detected. This is an interesting case, as it is rare that a varicose aneurism requires amputation, and demonstrates that in all cases the method adopted by Hunter should not be employed.

CASE III.—*Abscess of the Uterus.*—The woman affected by this disease had not during life any symptom to point out its existence. After death there was discovered an obliteration of the neck of the uterus, and the dilated cavity of this organ contained a pint of pus.

CASE IV.—*Contusion of the Brain.*—In consequence of a fall a man, 50 years of age, was brought to the Hôtel Dieu in a state of commotion. In 24 hours the comatose symptoms, owing to the cerebral commotion, were partly dissipated; but, after remaining in a satisfactory condition for two days, comatose symptoms again supervened, with great prostration: an icteric disease ensued, accompanied by a frequent pulse, &c., resulting this time from compression of the brain. This condition might be attributed in part to the inflammatory condition of the contused part of the brain, and to an effusion of blood from fracture of the base of the skull, not recognised during life; the attention of the surgeon being distracted by several inflammatory symptoms of the elbow, arising from a deep lacerated wound. The following are the lesions found after death, which took place 20 days after the accident:—fracture of the occipital, parietal, and petrous portion of the temporal bones, effusion of blood under the dura mater, and in the cavity of the arachnoid; traces of contusion of the posterior right lobe of the brain, and at the anterior extremities of each hemisphere, in many parts of the cortical substance, and of the pia mater; the vessels

were much injected; slight metastatic abscesses were found in the lungs; the other viscera were healthy.

A new Method for the Extraction of large Calculi from the Bladder by the Perinæum. Memoire read at the Medico-Chirurgical Academy of Naples.

BY M. MARIANO PANTALEO, OF NICOSIE
IN SICILY.

The author, in the first place, establishes as a fact, that the lateral operation, by incising the neck of the bladder, is the one most generally adopted by all practitioners, and the advantages, resulting from it, are much superior to those of the other forms of the operation. The only objection, he says, that can be made to it, is the difficulty or impossibility of extracting large calculi; and the danger resulting from the attempts made for their extraction he has endeavoured to lessen. He performs it by a double incision of the prostate, but makes the direction of the incision, in a sense, different to that which has been proposed by M. Dupuytren and M. Senn,—thus the left half of this incision, taking the direction of the ischium, as in the simple lateral operation, the right half passing obliquely upwards and to the right, so that the incision of the prostate forms a simple diameter, oblique from right to left, and from above to below.

According to M. Pantaleo, the superior part of the prostate opposes a strong resistance to the dilatation of the neck of the bladder, when the inferior incision is alone made, and consequently he believes it rational to destroy this obstacle. It is this, he believes, that caused M. Martineau to be so successful in his operations, and to lose only two subjects out of eighty-four. To wait the difficulties before making this second incision would only be rendering the operation more difficult and dangerous; finally, even if the calculus be small, the advantages obtained from the double incision are greater, without adding any inconvenience to the operation.

All the followers of the bilateral operation have already reasoned on this subject; but the following are the objections, made to the ordinary proceedings, by M. Pantaleo. The incision recommended by Dupuytren, particularly in adults and old people, exposes the bulb of the urethra to great danger; or, if in

order to avoid it, the incision is carried nearer the anus, there is great risk in perforating the rectum. By the incision of Beclard, the bulb may be more easily escaped, but the danger is still greater of wounding the rectum, and, by making the internal incisions parallel with the external, exposes both sides to urinal infiltrations. Lastly, the two incisions, recommended by Dupuytren, unite at an angle, and leave untouched the superior middle of the prostate gland, which is a great obstacle in dilatation. Although many of the objections made by the author might be replied to, certainly his method destroys a great number of inconveniences, and renders the operation, in cases of large calculi, less dangerous.

The instrument made use of by the author is a double lithotome, the blades of which expand in opposite directions to a certain extent, as in the ordinary instrument. The external incision made in the perinæum is of the common extent, and in the oblique direction, as in the ordinary lateral operation; the membranous portion of the urethra is incised to the extent of three or four lines; the lithotome is then directed into the bladder, along the groove in the catheter, the size of the stone is ascertained, and, according to its volume, the blades of the lithotome are separated. The lithotome introduced in the direction of the external incision, its handle is depressed, and the instrument is withdrawn, with proper precaution, with the blades open. From this manoeuvre, there results an incision on the left inferiorly, and another on the right superiorly; and if the first incision has the depth of six lines, the second will have neatly divided the superior part of the prostate. The superior wound has a great tendency to unite by the first intention, in consequence of the declivity and size of the inferior, offering a greater facility than the former to the discharge of urine. The wound, thus formed in the prostate, is of the most regular form, parallel to that of the integuments, needing only simple dilatation for the extraction of the stone.—*Osservatore Medico.*

Curious Case of Apparent Death, which lasted Twenty Days.

Hufeland, who has written so much on the danger of hastened inhumations, and on the uncertainty of the signs of death, has just

published a very curious fact, which we extract from the Journ. des Pract. Heilkunde.

In the hospital of Paderborn, a young man laid apparently dead for twenty days, before any preparations were made to bury him, in consequence of the non-evident signs of death; he had been recently cured of tertian ague, and came into the hospital for phthisis pulmonalis. The day of his last expiration, he suddenly opened his eyes, and for a few minutes pulsation at the wrist could be felt, but the beats were irregular and very feeble. The eschars, which were made, if possible, to restore animation, suppurated till the fourth day; on the fifth there was movement of the right hand, which became closed; from the sixth to the ninth there was a vesicular eruption on the region of the back. The limbs remained flexed; on the eighteenth day there was still redness of the lips; for nine days the skin appeared folded on the forehead, and the countenance presented a non-cadaverous aspect. The body, which was kept for nine days in a warm room, became not the least putrid or shrivelled; on the twentieth, signs of putrefaction commenced, after which period it was buried.

THE PREPARATIONS OF COLCHICUM.

THE bulbs, and sometimes the seeds, of colchicum (*colchicum autumnale*) form the basis of various medicinal compositions, which are sufficiently efficacious to call forth the attention of all persons who employ them. It is well known that these bulbs, when mixed with alcohol (two parts of fresh bulbs and four parts of alcohol), form *l'eau médicinale d'Huxon*, so extolled for many years. Unfortunately the various forms for preparing the preparations of colchicum, both in the old and new Pharmacopœias, and various other works, agree so little, that it renders the use of these compounds both uncertain and very variable; besides, the bulbs of colchicum are very liable to differ in their properties, owing to the season in which they are gathered*. It is difficult to say which is the most favourable season for gathering the bulbs; common report states it should be about the month of August,

* This doubtless applies to other bulbs equally in use.

when the bulb is in its full luxuriance. According to the last publications of MM. Geiger and Lesse, who trace the principles of colchicum to a substance liable to crystallise, and rather different from veratine, which they called *colchicine*, one would be, at least in this case, tempted to substitute the preparations of colchicum for fixed quantities of this organic substance (when its medical properties are well established), mixed or not with some gummy or other substance, capable of imitating those which are found in the plant. We certainly adopt, in most cases, the judicious opinions of M. Polydore Boullay, on the danger of changing pharmaceutical formularies, and these opinions are stated in too liberal a spirit not to be universally appreciated; we, however, think that the use of certain active principles, separated from vegetable active substances, offers, on the other hand, very great advantages, for they generally contain the most essential properties of the substances from which they have been extracted, and it is very easy to modify or attenuate their effects by mixed ingredients. We shall at least be sure of acting upon precise quantities and identical compounds, which seldom takes place, not only with colchicum, but with a great many other roots, barks, seeds, &c., the composition or proportions of which may vary according to the time of gathering, the year, and the adulterations of the trade, which are not always easily detected. Finally, the manner of administering this medicine is still favourable in these cases, by the facility of concentrating in a very small volume the active principles which form the basis of a pharmaceutical preparation.—*Journal de Pharmacie, June, 1834.*

DISEASES OF BOKHARA.

Extracted from "*Travels into Bokhara*," &c.

BY LIEUT. ALEX. BURNES, F.R.S.

Vol. II. p. 180. Murray, London, 1834.

"Among the diseases of Bokhara the most distressing is the guinea-worm or *dracunculus*, here called '*rishtu*:' it is confined to the city. The inhabitants believe that the disease arises from drinking the water of the cisterns in summer when they become fetid and infested with animalculæ. Travellers suffer as much as the inhabitants; but the disease does not

show itself till the year following that on which they have drunk the water. Many of the Afghans are attacked after returning from Cabool; and, whatever be the cause, it assuredly originates from something peculiar to Bokhara, since all other parts of the country are free from it. It is supposed that one-fourth of the whole population of Bokhara are annually attacked with guinea-worm. This prevalence of the complaint has given the natives a dexterity of extracting them, quite unknown in other countries. So soon as it is discovered that one has formed, and before any swelling has taken place, they pass a needle under the middle of the worm, and, rubbing the part, draw it out at once. They are generally successful; but if the worm breaks the wound festers, the pain is excessive, and few recover under three months. If the animal be coiled in one place the extraction is simple; if deep in the flesh, more difficult. If the swelling has commenced, they do not attempt the operation, but allow it to take its course, and endeavour to draw it out by degrees, as in India. These worms vary in length from three to four spans. It is said that guinea-worm is most common among people of a cold temperament, but it does not attack any particular class. The better orders of people, attributing it to the water, send to the river for their supply, and never drink that of the cisterns till it is boiled. It is not to be supposed that I can give any solution of the cause of this disease; the doctors of Toorkistan believe it to be a worm generated from the causes above-mentioned, nor can I credit its arising from the animalculæ of the water.

“Another disease of the country is the ‘mukkom’ or ‘kolee,’ a kind of leprosy. Those afflicted with it are considered unclean: it does not cover the body with spots as in common leprosy; but the skin becomes dry and shrivelled; the hair of the body falls off, the nails and teeth tumble out, and the whole body assumes a horrible and unseemly appearance. The disease is believed to be hereditary, and to originate from food. It is fearfully prevalent in the districts of Samarcand and Meeankal; also in the neighbouring states of Shuhrsubz and Hissar, all of which are rice country. Some state it to be caused by the use of the intoxicating spirit called ‘boozu,’ which is distilled from black barley; but that

liquor and mares’ milk are not used in Bokhara. The disease affects the general health, and is incurable. The most humane people will tell you it is a curse from God, and drive the unfortunate sufferer from them. A separate quarter of the city is assigned for those who are afflicted, as was the case among the Jews.

“That scourge the cholera morbus has been felt in all these countries. It appears to have taken the route of the caravans, and advanced from India step by step into Eastern Europe. It raged for a year in Cabool; it then crossed Hindoo Koosh, on the following season, and desolated Balkh and Koon-dooz. For a year it fluctuated between the valley of the Oxus and Herat; it then attacked Bokhara, Kokan, and the other Usbek states; and, after devastating the country, passed on to Khiva, Orenburg, and Astrakhan. The faculty have discovered no remedy for the cholera morbus.

“The inhabitants of Toorkistan are subject to a constant dryness of the skin; many of them lose their eyelashes and eyebrows, and their skin becomes wrinkled and tawny. Whether the diet or dryness of the climate causes these appearances I know not. The Usbeks seldom eat horse-flesh, though it is believed that they live upon it. It is considered heating food, and is besides expensive. Mutton is preferred, and none but the lower orders eat beef. A sheep is killed, and the entire tail, however large and fat, is melted up with the meat and cooked in a single boiler. They are fond of every thing oily, and also use much cheese and sour milk. Ophthalmia is a very common complaint in Toorkistan: fevers are rare: in Balkh, rheumatism is prevalent. In the city of Bokhara rickets are common, and the children have generally a puny and unhealthy appearance, which is not observable in the grown up people of the country. Among their medicines I heard of an oil extracted from the dung of sheep, which is considered a specific for the sprains, bruises, and hurts of cattle, it is very pungent, and the flies shun the parts rubbed with it. I have been assured of the bone spavins of a horse being reduced by an application of this oil. They procure it by a distilling process.”

A CASE OF UNUNITED PARTURIENT LACERATION OF THE RECTO-VAGINAL SEPTUM, SUCCESSFULLY TREATED WITH METALLIC LIGATURES.

BY JOHN P. METTAUER, M.D., OF PRINCE EDWARD COUNTY, VIRGINIA.

THE lady, whose case forms the subject of the following communication, was about thirty years of age when the accident occurred. Her health and constitution, as far as I could learn, had been good down to the time of her confinement, which took place some time during the month of October, 1831. The pregnancy, which resulted in the laceration, was her first, and from its history must have been more fortunate than usually follows late conceptions. Her labour was protracted and very tedious, having continued more than three days, but was marked by no other important event save the accident. Six months after the laceration took place I was consulted, and my opinion and advice requested. The history furnished at this time induced me to regard it as a case of ununited laceration; and I feared that the surfaces had healed, so far, at least, as to require denudations by art, before a reunion was likely to take place between them. An opinion to this effect was expressed to the husband of the lady, an intelligent and highly respectable gentleman of a neighbouring county; I also informed him, that it was more than probable ligatures would be required before a complete cure could be effected. Some five or six weeks after this interview, the lady was conveyed to my neighbourhood, and placed under my immediate management, having resolved to waive all considerations of delicacy, a sacrifice indeed, if she could only obtain partial relief from her most loathsome and health-destroying infirmity.

In assuming the weighty responsibility of such a case, I am free to own, that I felt much embarrassment, the more so, as I was called upon to act in a matter of great delicacy, to say nothing of its intrinsic difficulties, without having had time to avail myself of the advice of some of my experienced brethren, or to think much upon the subject. The anxiety and determined purpose of my patient did not

permit me long to doubt and fear, and, without further delay, I was summoned to examine into the nature of the infirmity.

The examination disclosed a complete disunion of the recto-vaginal wall, from the verge of the anus three inches up the rectum, and, as was feared, the divided surfaces had healed in every part of them. The cleft terminated superiorly in an angle somewhat obtuse, and the rectum had contracted upon itself, so as to render its several teguments a mere band of the width of five-eighths of an inch. On each margin of this band a whitish line was to be perceived, commencing in the angle above, and continuing down to the verge. These were doubtless cicatrices, and pointed out the margin of the divided rectum. The retaining faculty of the sphincter was completely destroyed, and the unfortunate lady from that cause had been compelled to submit to constant confinement, in a recumbent posture, to prevent the loathsome accident of involuntary dejections. Long-continued irritation of the wound had induced, in the gastrointestinal organs, a morbid susceptibility, which subjected the lady to frequent attacks of colic and diarrhoea from the slightest errors in diet. To remedy so afflictive an infirmity, it was necessary, not only to repair the breach of the rectum, but also to restore the tubular form of the rectum, and contractile power of its sphincter muscle. These ends were accomplished in the following manner:—The patient was placed very nearly as in the position for lithotomy, with the knees held apart, and exposed to the direct light of a window: the cleft was readily brought into view, by separating the vulvæ and anterior parietes of the vagina. Denudations, three-fourths of an inch in width, extending from the angle down to the verge on each side, were now effected along the cicatricial lines, and a little exterior to them, by the aid of hooks, scissors curved on their flat sides, and scalpels, using them according to circumstances. As soon as the wounded surfaces ceased to bleed, they were approximated, and for this purpose leaden ligatures were employed. These were introduced from within, and in succession, from the angle down to the verge, at the distance of one-fourth of an inch apart; care was taken to give them good hold: they were made to include at the same

time a belt of undenuded substance on each side. Needles very much curved were employed, with a noose of twisted and waxed silk in the eye of each, upon which to hang the loops of the metallic ligature previously formed. Dr. Physick's forceps were used for the introduction of the needles, which was found a very handy and convenient instrument. As the ligatures were applied they were tightened, so as to bring the abraded surfaces in contact, and then their ends were twisted together and cut off of convenient length. About twelve ligatures were required to close the breach. From time to time the ligatures were tightened by twisting them, and the vaginal margins of the laceration cauterised with nit. argent. to favour the formation of granulations, which it was judged would greatly strengthen the union in this part. The patient was confined to the recumbent posture in bed, with the knees tied together, to prevent, as far as possible, any disturbance of the wound. A diet of liquids was directed, as least likely to distend the lower bowels, or to elicit alvine evacuations. For four days the bowels reposed; and, as a proof that the ligatures held the surfaces securely and perfectly in contact, the evacuation which now took place did not derange the parts, or inflict much pain; and it was now, for the first time since the accident occurred, that the propensity to deject could be resisted. In six weeks the ligatures were cut away, the parts having united perfectly. Leaden ligatures were preferred in the management of the foregoing case, as experience had proved them not only less irritating and liable to cut out when tightly drawn than any other material with which I am acquainted, but infinitely more convenient and effective in maintaining a uniform and perfect apposition by the ready facility of simply twisting them, and as a proof that the leaden ligature may act forcibly for a long time without cutting out, when they were removed in the present instance, it could not be perceived that any material encroachment had been made upon the margins of the cleft. The lady is now perfectly restored, thirteen months since the operation was performed, as the following extract from the husband's letter to me will evince:—

“and can now with pleasure and most grateful acknowledgments to your skill and manage-

ment have it to say that she feels no inconvenience from the injury sustained at the time she had her child; and she further says that if her condition was similar to the one she was placed in before you operated, she would freely and willingly submit to it again, if she could only believe the same degree of benefit and relief was to be the result.”—*American Journal of the Medical Sciences.*

DESCRIPTION OF THE CALCULO-FRACTOR FOR PULVERISING THE CALCULUS IN THE BLADDER.

BY FRANCIS L'ESTRANGE, A.M., M.R.C.S.I.,
Dawson-street.

FROM the earliest ages it appears to have been a desideratum in surgery to discover some means whereby the dangerous operation of lithotomy might be rendered unnecessary; thus we find various preparations at different times tried and extolled for their supposed solvent powers. It does not seem, however, that the grand object in view was destined to be attained until modern invention should contrive the expedient of breaking up the calculus in the bladder, and having the detritus subsequently washed out through the urethra. It would be quite superfluous to draw a comparison here between lithotrity and lithotomy, that has already been ably done by the different gentlemen who have written on the former operation*. Still it must be admitted, that however good the principle, yet in practice this operation has been found to labour under many defects. For example, with Baron Heurteloup's "Percuteur," which, taken altogether, appears to be the most perfect of the instruments as yet used for this purpose, there is almost a certainty of the instrument, or stone held by it, or both, being driven by the hammering against the sides of the bladder, and thus causing incalculable mischief. So great a defect has this been found, that to obviate it a bed has been constructed, and the patient being fixed thereon, the percuteur is introduced and fastened to an iron bar placed in front for that purpose; the staff is thus certainly rendered almost immoveable, but as the

* Vide Lithotrity, *Lancet*, 1829, 30, 31; *Lithotrity and Lithotomy compared*. T. King, M.D., 1832.

patient cannot be equally well secured, and as the slightest motion on his part might cause as great or even greater mischief, the object seems to be as far as ever from being accomplished. Nothing is here advanced against the inconvenient unwieldiness and great expense of such a complicated system of instruments, beds, &c. Again, the detritus of the calculus, by lodging between the curved blades of the instrument, prevents their closing, and thus increases, in some instances, considerably, its diameter; this, in all cases, must cause extreme pain on the withdrawal of the instrument, and has in particular instances produced laceration of the parts and hæmorrhage. To do away with these and other objections, the instrument, of which sketches and a description accompany these remarks, has been invented. Its advantages are *extreme simplicity*; it being acted on by a screw of such power as to pulverise any calculus found within the bladder, thus doing away with the dangers of percussion; a stilette, which passes in a groove between its blades, by which the detritus lodged there can be at once removed; a claw fastened on a pivot to the screw, so as to allow of its being fixed at will to the upper blade of the instrument, which can then, by turning the screw backwards, be separated *without the slightest shock* from the inferior one, should these have become agglutinated by the broken down calculus and its animal mucus. Finally, should any case occur, or any individual still prefer the operation with the hammer, by removing the vice this can be performed as heretofore, the operator enjoying the additional advantage of the stilette. There are many other desirable qualities that might be enumerated as possessed by this instrument; but it is not intended to trespass at present any further on the reader's time; suffice it to say, in conclusion, that there are but two cases requiring the operation of lithotomy to which it is not applicable, namely, a calculus contained in a pouch, or a bullet in the bladder.

Explanation of the Plate.*

FIG. 1. Represents the instrument as in the act of being closed by the power of the vice,

* The Medal of the Royal Dublin Society was awarded for the instrument. The operation with the *Calculo Fractor* was performed

the point of the screw playing in a socket at the extremity of the handle, which causes direct pressure downwards, without producing any rotation whatsoever at that portion of the instrument in the bladder, and thereby preventing any injury being done to the mucous membrane of that organ.

FIG. 2. The vice, having a screw, with a double thread. The weight of this portion of the instrument is an advantage to the operator, by enabling him the better to keep steady the instrument, while this part is grasped in his left hand, which is to be supported on his left knee, the foot being placed on a low stool in the position for operating.

FIG. 3. The claws of the instrument open their wedge-like teeth well adapted for splitting, also the detritus rod scraping the bottom groove, so as to remove all particles of the broken stone that always remain preventing the claw from being closed, and thereby causing great laceration of the urethra and hæmorrhage.

FIG. 4. The box of the instrument, the handle of the upper claw in which the socket to play in is placed, also the canal for the detritus rod.—*Dublin Journal of Medical and Chemical Science.*

ROYAL COLLEGE OF SURGEONS IN LONDON.

[Circular.]

*Royal College of Surgeons in London,
July 2nd, 1834.*

GENTLEMEN,—In consequence of occasional irregularities that have taken place in the certificates, transmitted to the Court of Examiners of this College, I am directed by the Council to acquaint you, that it is their anxious wish to have some plan devised and adopted by the lecturers at the various medical schools of the United Kingdom, whereby the regular attendance of the students on the lectures at such schools may be enforced and registered, so as to entitle the students to

this day (June 4th), with complete success, by the Surgeon-General, (there were present also Surgeons Adams, Hargrave, and Smyly,) the peculiar advantages of this instrument having been exemplified in a remarkable manner.

receive, and to justify the lecturers in giving, certificates of attendance, the accuracy of which may be relied upon by this College, and which the greatest vigilance and circumspection on the part of the lecturers cannot at all times secure under the present system, where there is a want of some such check and registry.

The Council will consider themselves obliged by your attention to their wishes, and will thankfully receive any suggestions you may be pleased to offer on the means which, in the opinion of yourselves and your colleagues, may be best adapted to effect this important object.

I have the honour to be, Gentlemen,
Your most obedient humble servant,
EDMUND BELFOUR, *Secretary.*

Regulations of the Council respecting the Professional Education of Candidates for the Diploma.

- I. Candidates will be required to bring proof:
 1. Of being twenty-two years of age.
 2. Of having been engaged five years in the acquirement of professional knowledge.
 3. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during two anatomical seasons*.
 4. Of having attended at least two courses of lectures on surgery, delivered in two distinct periods or seasons, each course to comprise not less than sixty lectures.
 5. Of having attended lectures on the practice of physic, on chemistry, and on midwifery, during six months; comprising not less than 60 lectures respectively, and on botany and materia medica during three months.
 6. Of having attended during twelve months the surgical practice of a recognised hospital in London, Dublin, Edin-

* An anatomical season is understood to extend from October to April inclusive, and to comprise at least 140 lectures on anatomy and physiology, occupying not less than one hour each, given on separate days; and at least 100 demonstrations of the like duration, given in a similar manner; exclusive of dissections, of which distinct certificates are required.

burgh, Glasgow, or Aberdeen; or for six months in any one of such hospitals, and twelve months in any recognised provincial hospital.

- II. Members and licentiates in surgery of any legally constituted College of Surgeons in the United Kingdom, and graduates in surgery of any university requiring residence to obtain degrees, will be admitted for examination on producing their diploma, license or degree, together with proofs of being twenty-two years of age, and of having been occupied five years in the acquirement of professional knowledge.

N.B. Certificates will not be recognised from any hospital unless the surgeons thereto, or a majority of them, be members of one of the legally constituted Colleges of Surgeons in the United Kingdom; nor from any school of anatomy, physiology, surgery, or midwifery, unless the respective teachers be members of some legally constituted College of Physicians or Surgeons in the United Kingdom.

Certificates will not be received on more than two branches of science from one and the same lecturer, but anatomy and physiology, demonstrations and dissections, materia medica and botany, will be respectively considered as one branch of science.

In the certificates of attendance on hospital practice, and on lectures, the dates of commencement and termination are to be inserted in words at full length.

All the required certificates are to be delivered at the College ten days before the candidate can be admitted to examination.

By order of the Council,
10th July, 1834. EDMUND BELFOUR, *Sec.*

IMPROVED METHOD OF ADMINISTERING EPSOM SALTS.

DR. JAMES HENRY, of Dublin, recommends the sulphate of magnesia, given according to the following formula, as an agreeable, safe, and efficacious purgative. Saturate any quantity of cold water with sulphate of magnesia; filter through paper, and add to every seven ounces of the solution one ounce of the *dilute* sulphuric acid of the Dublin or Edinburgh Pharmacopœias.—*Amer. Journ., May, 1834.*

MORISON'S PILLS.

The Trial at York.—Verdict "Manslaughter."

A FORTNIGHT ago we published a full account of an inquest at York upon a young man, whose death was alleged to have been hastened by large and repeated doses of Morison's Pills, during an attack of small-pox. One Webb, a publican, and an agent for the sale of the pills, was the medical practitioner upon the occasion, and was in consequence put upon his trial for having ignorantly tampered with the life of a human creature. We have now to record the result of the trial. After a patient investigation before one of the ablest judges of Westminster Hall, he was found guilty of "Manslaughter." Upon examination we find the evidence at the inquest includes all the material facts elicited at the trial, which it is unnecessary therefore to repeat. The analysis of the pills seems, however, to have been more accurately given on the latter occasion. Mr. West, a respectable chemist, stated the results of his investigation:—

"The pills No. 1. averaged two and a quarter grains each pill, and were composed of aloes and colocynth, together one grain, but in what proportion he could not ascertain; gamboge half a grain, and cream of tartar three quarters of a grain. There was also a very small portion of ginger. The pills No. 2 averaged three grains each, and contained of aloes and colocynth one grain, gamboge one grain and a half, cream of tartar half a grain, and ginger as before."

The counsel for the prosecution referred

to the case cited by the coroner on the inquest, and to another case at the last assizes, before Mr. Baron Alderson; when a sailor was convicted of manslaughter, for having rashly and ignorantly occasioned the death of a man by giving him a large dose of opium, because his own wife was in the habit of taking it. The learned counsel dwelt forcibly upon the criminality of persons unskilled in medicines and diseases, attempting to tamper with them, where there are so many medical establishments and regularly educated practitioners spread over the country. The same point was insisted upon by the learned judge, in his address to the jury, although he admitted, as the counsel for the prisoner contended, that the statutes for licensing medical and surgical practitioners did not, and could not, make the distinction to permit one man to escape a conviction for felony, and to convict another for the same offence; in fact, it applied to both, and if either acted ignorantly, in administering strong and improper medicines, the law could reach them both. But in estimating the ignorance and rashness of the accused, it was no slight consideration that he undertook, whether gratuitously or for gain it mattered not, a duty which is appropriated by common sense to a numerous and educated profession.

The trial of St. John Long for the murder of Miss Cashin was cited for the prisoner,—and if Morison, or Moat, or both, stood at the bar in lieu of their agent, the analogy would have been complete,—Morison and St. John Long might both have produced corresponding lists of wonderful cures, and the ardour of the old fool, who swore he sold his Bible to purchase Morison's Pills, and would sell another Bible if he had it for the same purpose, might be paralleled by

the enthusiasm of equally ignorant lords and ladies.

It is to be deplored, that the miserable agent of the supreme quack should have to bear the whole consequence of this audacious quackery, while the fellow, who drives his carriage on the profit of his infamous impositions, escapes unscathed. We intreat, we implore the attention of Mr. Warburton to this intolerable nuisance of quack medicines and quack doctors. It seems almost useless to appeal to the public press not to lend its aid in advertising their base practices. The most respectable newspapers contain daily a number of impudent medical advertisements, direct impositions upon the ignorant and credulous. An operative in Warren's blacking manufacture once observed, "We keeps a post." Every regular quack, in like manner, *keeps* a newspaper or a magazine for his sole use, and it is notorious, that the expences incurred by such persons in advertising are enormous. The nuisance has now risen to that height that the interference of the legislature is necessary for the protection of the public health.

THE PARLIAMENTARY COMMITTEE.

A COTEMPORARY is much enraged at the lengthened inquiries of the Parliamentary Committee, and notifies that a hint was given from the proper quarter to wind up the investigation. We are not surprised at our cotemporary's vexation: it is perfectly consistent in him to maintain that the whole business should have concluded with the examination of the magnates, upon whose opinions the legislature should have proceeded to re-edify the profession. The sources of his information are quite unknown to us or to any one else; and we apprehend Mr. Warburton is not the

man to be interfered with in the discharge of a public duty. We are ourselves most anxious to see the conclusion; and we hope before the session terminates we shall have the pleasure of examining the evidence. All we can say at present is, that the Committee never was more actively engaged than at the present moment; and when we add that the officers of the Irish Medical Corporations are this week in course of examination, our readers will admit the inquiry is of a rather important nature.

LORD BROUGHAM ON HOSPITALS AND DISPENSARIES.

"HE was well aware that he was speaking on the unpopular side of the subject, but the truth must be told. The only safe kind of charity—the only species of charity that was not liable to abuse—was an hospital for accidents. Accidents were things that no man could calculate upon or provide against; and of this they might be certain, that the existence of such an hospital would in no way tend to increase the number of accidents. The next charity in point of safety was that of dispensaries. He would pause, however, before he would go so far as to say that that was a safe species of charity not liable to abuse. He had been of such an opinion some years back; but, upon consideration, he had altered it. Every one should look forward to and provide against that sickness, those ailments to which the lives of all were necessarily exposed. Though he did not go to the extent of objecting to dispensaries, therefore, he doubted much that their establishment was in accordance with sound principle."

—(Speech on the Poor Laws.)

We are really surprised to find sentiments like the above entertained by Lord

Brougham, as they clearly show that his Lordship knows very little about the incalculable value of hospitals and dispensaries to the poor. According to his views, such hospitals as St. Bartholomew's, Guy's, St. Thomas's, &c., are useful so far as they are open to accidents; but the advantage they afford of admitting persons labouring under fever, inflammations of the lungs and bowels, dropsies, &c., are valueless. We agree with the noble Lord in the opinion that few men will break their legs and necks to obtain admission into a hospital; and therefore it is most true, that the existence of such hospitals in no way tends to increase the number of accidents!!

But, we apprehend, that it is exacting too much from humanity, to expect the daily labourer, who is the object of the poor laws, should have a store in reserve for proper medical assistance in cases of severe illness, which are as little to be calculated upon as accidents. A man may have a fever, or pleurisy, from a hard day's work, as well as a broken leg. The little that this class of persons can afford to pay for medical assistance would never procure for them proper advice, and they would become the prey of quacks of all sorts. In fact, one of the objects of dispensaries was, to put down the trade of the mountebank quack. There is, however, a class not the proper objects of charitable dispensaries, who avail themselves of their gratuitous humanity, though they are able pay for medical attendance. This is a to nuisance: it diminishes the reasonable remuneration of a liberal and expensive profession; and, as the labourer is worthy of his hire, we should be delighted to see this fraud put down.

NEW REGULATIONS OF THE ROYAL COLLEGE OF SURGEONS.

WE beg to direct the notice of our junior readers to the new regulations issued by the Royal College of Surgeons, and also to the circular sent to the different Lecturers. It behoves medical students to consider these documents maturely.

IMPORTANT TO LUNATIC ASYLUM KEEPERS.

THIS morning (Thursday) an application was made by counsel, on the part of Mr. Joseph Taylor, who kept a lunatic asylum, called The Retreat, at Cottingham, near Hull, stating that Mr. Bethell, M.P., and two other visiting magistrates, had withdrawn his licence. The magistrates had simply represented to his Lordship what they had done. Affidavits were read in explanation of some circumstances supposed to have influenced the magistrates. This was the first application of the kind. His Lordship doubted whether he had any judicial authority, it appeared to him to be simply executive. However, he directed the affidavits to be filed, and his Lordship added he would show them to the magistrates, and ask them whether their opinion would be altered upon the statements therein contained.

SABRE WOUNDS OF THE KNEE, COMMUNICATING WITH THE JOINT.

DENNIS FOGERTY, æt. 17, a maker of bricks, was admitted into No. 3 Ward, on the 27th of March, with five incised wounds of the left leg, from one and a half to three inches in length. One is situated just above the head of the fibula, and communicates with the knee joint; another is situated immediately below the patella. From both these openings issue synovial fluid. He was supposed to be a house-breaker, and the wounds were inflicted

by a gentleman with a sword. The wound dressed with adhesive plaster, and bandaged.

28th. Mr. Banner visited the patient this morning, and considering the knee required dressing, removed the bandage, &c. From the opening below the patella there was a discharge of serum, and on it were distinctly seen globules of synovia. The wounds were dressed with adhesive plaster and compresses, and spirit lotion ordered to be applied constantly.

The lad passed a quiet night, and is quite free from pain; the bowels are constipated, and the pulse full and quick. He was ordered the senna draught, and sixteen ounces of blood to be taken from the arm.

This case continued to do well until the 4th of April, when there was observed a puffiness of the knee, and a slight increase of frequency in the pulse. The puffiness continued to increase until the 9th, when, on removing the dressing, there was observed a substance projecting through the upper wound at the side of the joint, perfectly transparent, and not unlike the humours of the eye in appearance. This was punctured, and about one ounce of fluid escaped, which was perfectly transparent, and of an oily, sticky nature; occasionally, also, small particles of lymph escaped. He has never experienced the slightest pain since receiving the injury, and his health has been good. It was ascertained that he had left his bed for two days previous to this. The wounds were dressed simply, and slight pressure made.

11th. There was a second escape of about an ounce of the same kind of fluid, which was now clearly ascertained to come from the joint, as the opening whence it issued had become very perceptible. Mr. Banner introduced a probe, which passed easily through the joint. From a careful examination the fluid was considered to be pure synovia. The patient is quite free from bad symptoms; he is easy, sleeps and eats well. This discharge escaped for two days longer, when it entirely ceased.

24th. The wounds are nearly healed, and the boy healthy.

30th. He was made an out-patient.—*Liverpool Med. Journ.*

SYPHILIDE TUBERCULEUSE.

E. F., æt. 30, a married woman, applied on the 8th of April, to Dr. Duncan. The face and forehead were covered with coppery tubercles, of six weeks' duration; and there was a painful node on each tibia. She had contracted syphilis from her husband more than once, the last time about three years previously, since which period she had taken no mercury.

R. Hydrarg. ioduret. gr. x.
Dec. sars. co. Oj. S.
Sumt. cyath. vinos. ter de die.

On the 10th the mouth was sore; and when seen, two or three days afterwards, the eruption had begun to decline. She afterwards continued the sarsaparilla alone, and in a short time hardly any traces of the tubercles remained.

L. S., æt. 27, a sailor's wife, applied some time ago with an eruption of a similar character, occupying the face and arms. The ioduret of mercury, given as above, having affected the mouth in a few days, the following was substituted.

R. Potass. hydriod. ℥j.
Aq. distil. 3 x. S.
Sumt. 3 j. ter de die.

The eruption, which improved rapidly from the time the first medicine was ordered, had quite disappeared at the end of a fortnight. About a month afterwards, however, it returned, after exposure to cold; and it again disappeared, but more slowly than before, under the use of blue pill and decoction of sarsaparilla.

SYPHILIDE SERPENTEUSE.

Three or four months ago, a woman, about 35 years old, (the particulars of whose case we are unable, at this moment, to refer to) applied to Dr. Duncan, at the Dispensary. A line of ulceration (formed by the coalescence of tubercles in groups of five or six, afterwards ulcerating at the top) extended from the lower dorsal vertebræ to the top of the right shoulder. After using, for a short time, the protiodide of mercury internally, and externally in the proportion of a scruple to an ounce of lard, the ulceration healed, leaving

an irregular depressed copper-coloured cicatrix.

In the two cases first mentioned, a smaller dose than usual of the protiodide of mercury affected the mouth; but in most cases of this kind, in which the medicine has been given at the rate of 2 grs. three times a day, Dr D. has found it very speedily produce salivation, and, generally, exert a beneficial influence on the disease. It is much used in the Hôpital St. Louis, by Bielt, who says it is very successful after iodine and an interval of rest. When carried far, it produces considerable irritation.—*Liverpool Med. Journal.*

British Hospital Reports.

ST. THOMAS'S HOSPITAL.

Diseases of the Membranes of the Brain.

THE diagnosis of diseases of the different membranes and the substance of the brain is at all times exceedingly difficult; and, although many nice distinctions have been laid down by nosologists, and diseases of the contents of the cranium divided into a considerable number of distinct species, such as phrenitis, paraphrenitis, phrenismus, sideratis, siriasis, sphacelismus, typhomania, calentura, and a host of others, it is at all times difficult at the bed-side, when the symptoms are severe, to recognise the particular portion of the brain, or its meninges, which is affected, these parts being so intimately connected one with the other, that disease of the one, whether it commences in the encephalic substance or its membranes, frequently produces an affection of the other. Yet, as the disease advances, whether it be confined to the membranes, parenchymatous structure of the brain, or both, the particular parts affected may in general be distinguished.

To give, however, an accurate diagnosis of such diseases, every pathognomonic sign should be understood, the course of every nervous filament ascertained, and the connexion of every filament with the other parts of the body considered. These are, at first sight, insurmountable difficulties, and they will doubtless for a long time remain undiscovered. If, however, different portions of the brain perform separate functions, and, according to the functions, the external actions are controlled, nothing can be more simple than to discover what are the impaired actions manifested, which at once would lead to a suspicion of the part diseased. But some difficulties here present themselves, and which require much attention to overcome; that is, to get an exact history of the mental powers previous to its occurrence, to discover which faculty in the first instance is impaired, and

the regular progression of the disease. By ascertaining exactly these facts, the seat and extent of disease would at all times be detected, and the treatment must be regulated according to the severity of the symptoms. Again, we may have each of the membranes of the brain separately affected, whence some pathologists have set down arachnitis as a sub-variety of the meningic form; yet the pathognomonic signs are so obscure, and the diagnosis of such little utility, that no benefit can result from such nice distinction; moreover, in nine times out of ten, the pia mater is at the same time affected, and the treatment indicated is always similar.

The symptoms of membranous affections also vary in different parts: for example, disease of the superior and lateral parts produce delirium and coma, whilst a morbid state of the membranes at the base of the cranium affects the different organs supplied by that portion of the brain situated above the seat of disease, in consequence of the thickened state of the membranes, or from effusion caused by the meningic affection. It has been stated by many writers, that symptoms are frequently mistaken for causes, and the former combated by treatment, whilst the latter continue to increase; and such, we may say, is too frequently the case. The symptoms of disease, especially of the nervous system, from its intimate connexion with every portion of the body, are exceedingly various, and from inaccuracy of previous history difficult to define. The following case will illustrate the symptoms of this disease in the first instance, though, in fact, before admission into the hospital, it was treated for disease of the alimentary canal.

CASE I.—John Burchett, a child, aged four years, who had previously enjoyed good health, was admitted, Nov. 30th, into Jacob's Ward, under the care of Dr. Elliotson. His friends stated, for two weeks previously he was attacked with occasional sickness, and his bowels remained in a state of costiveness, for which they had administered aperient medicines, and given mercury prescribed by a medical man. At the time of admission, he had severe pains in the head; countenance flushed; eyes slightly suffused; skin hot, particularly the scalp; tongue coated with a whitish mucus; occasional vomiting; costiveness; pulse varying from 71 to 80, neither full nor sharp.

Injections and purgatives were administered to obviate costiveness; the bowels remained confined; sickness continued; and all symptoms remained unchanged; and in the evening it was found necessary to give castor oil, and he was put in a tepid bath. In spite of these precautions the symptoms became more aggravated, his eyes appeared dull, pupils dilated, and pulse remained much the same. The next morning a slight evacuation from the bowels was obtained; the symptoms still continued the same. A mustard poultice was

applied to the abdomen, and Prussic acid given in an effervescing draught every six hours to check the sickness. Nevertheless, the child continued in great torture; pupils remained continually dilated, and contracted but feebly on the approach of a candle; pulse full, with a degree of sharpness; much pain in the head. Turpentine enemata were ordered, head to be shaved, and three grains of the hydrargyrum cum cretâ were prescribed three times a-day. Leeches also were applied to the head.

The costiveness still remained obstinate, and not till a drop of croton oil was administered could a copious evacuation be obtained. In consequence of much pain in the course of the longitudinal sinus, leeches were applied over that part. After their application the child appeared somewhat better; but at this time the mouth again became tender, from the hydrargyrum cum cretâ, and he took some notice of what was passing around him. These favourable symptoms only lasted for a short time, coma supervened, and strabismus ensued: pulse 120, very sharp. The pupil was now perfectly insensible to light, and the child continued restless. The next morning strabismus had disappeared; his cries became feeble; fingers and toes were contracted; legs bent on the abdomen; slight muscular twitches observed on the left side of the face; pupils remained dilated; urine passed involuntarily. Mercurial ointment was now rubbed on the head with camphor liniment: the next morning no muscular contractions were perceived; leeches were again applied to the head; croton oil was again administered to obviate the continued costiveness: about two hours afterwards his eyes were open, and motionless convulsions ensued, and about 11 o'clock death terminated his sufferings.

On the autopsy much serum was discovered between the dura mater and arachnoid, the latter membrane was exceedingly vascular. The lateral ventricles were distended with effusion; immediately behind the optic commissures a deposition of lymph was observed. Medullary substance softer than natural; abdominal and thoracic viscera were healthy.

In this case, the first symptom observed was obstinate costiveness, nausea and vomiting ensued, and continued for fourteen days before any decided cerebral affection was detected. The symptoms were slightly palliated by treatment; the cause left untouched continued to make progress, and when the child was admitted into the hospital, from the increase of the real seat of disease, other signs ensued, and the forerunning symptoms became more obstinate. At this time, from the advanced state of the affection, though rigorous and proper treatment was adopted, even the primary symptoms could be scarcely mitigated, and the extent of disease continued to impair the mental faculties, all of which were observed, in the progress of the case, to be deranged.

CASE II.—Cephalalgia.—W. B., a tailor,

aged 64, who had always enjoyed good health, of robust habit, was admitted October 24th into Jacob's ward under Dr. Elliotson. States about a week since was attacked with difficulty of discharging his urine, which in a few days afterwards was succeeded by giddiness and lancinating pains in the head, dimness of sight, and the appearance of objects before his eyes; also felt a dull aching pain about the region of his loins. His fingers became numb, which sensation extended up the arms; when admitted the symptoms remained much as he had described; countenance dull; bowels rather confined; tongue coated with mucus; motion of the pupils natural; action of the heart regular; pulse rather full. Bloodletting was immediately had recourse to; a large blister was applied on the back of the neck, and two grains of the pilul. hydrarg. were prescribed twice a day. In about four days his mouth became affected by the mercury; the blood that was taken from the arm was buffed and cupped; discharge of urine was more copious, and every symptom became much alleviated. His bowels were relieved by purgative medicines; by the 2nd of November the numbness had entirely vanished; small doses of mercury were continued, every symptom disappeared, and on the 26th of November he was discharged cured.

CASE III.—James Kirk, aged 38, was admitted 27th of February, 1834, under the care of Dr. Roots. States that he is employed in wine vaults, and till within the last two years had indulged in drinking. Three months ago was attacked with violent throbbing pain in the temples, giddiness, and shooting pains in the occiput; he is quite free from pain at times; vision impaired; eyes sore; slight suffusion of the conjunctiva; does not complain of numbness in any part of the body; nights restless, and sleep disturbed by frightful dreams; scalp hot, action of carotids more powerful than natural; pupils rather dilated; tongue slightly tremulous; pulse 108, small but firm; bowels confined. Dr. Roots combated the cerebral symptoms, by means of bloodletting, blistering and calomel. By the 1st of March all symptoms were much decreased; slept better, and vision became more perfect. At this time his mouth was slightly affected; the action of the mercury was kept up by smaller doses repeated at longer intervals; leeches were employed occasionally, in spite of which the symptoms continued, and he was unable to look into a book. Two grains of the sulphate of quinine were now prescribed every six hours, another blister was applied on the back of the neck, under which treatment his vision much improved, all encephalic symptoms ceased, and the 16th of March, by his own desire, he was made an out patient.

CASE IV.—Samuel Scott, aged 28, was also admitted, under Dr. Roots, into Luke's Ward, March 6th. For nine months he had

suffered from dull heavy pain in the head; much worse when in the recumbent position. About two months since he attempted suicide. Does not complain of any symptom in any other part of the body. Appears continually in low spirits. States that until within the last nine months he had been in the habit of drinking spirits freely, which he discontinued, in consequence of his sleep being disturbed by the appearance of phantoms. Eyes dull, pupils slightly dilated; bowels confined; pulse 92, small, and yields to pressure. Blood was extracted by means of cupping-glasses from the mastoid processes; five grains of blue pill were given twice a day, and the compound senna mixture occasionally, to keep up regular action of the bowels.

The symptoms were not much alleviated at first from this treatment; on the 14th of March he complained of a singing sound in the left ear; his mouth became affected by mercury, the action of which was kept up by smaller doses; the giddiness became more intense after the application of leeches, in consequence of which Dr. Roots desired they should be discontinued. The pain still continued; some tartar emetic ointment was applied to the scalp, which after frequent applications produced much irritation. The pain now diminished in urgency; bowels were open twice a day; alvine dejections of a light colour. The part was kept in a state of irritation for some days, by degrees the symptoms subsided, and he was discharged from the hospital quite cured.

(To be continued.)

WESTMINSTER HOSPITAL.

Ligature of the Common Iliac Artery.

Last Saturday Mr. Guthrie delivered a lecture at the New Westminster Hospital, on the case in which he tied the common iliac artery, and which has excited so general an interest in the surgical world.

The subject of this great operation was a lady, a native of Scotland, who had been liable to rheumatic pains in the hip, and one day happened to press her side violently against a table, to which accident she was always inclined to attribute the original cause of her disease. Some time after, a swelling made its appearance on the right buttock, which gradually increased in dimensions, and became very inconvenient, as she could not lie on that side, or even on her back. These symptoms becoming exceedingly aggravated, she was induced to come up to London, with a view to consult Mr. Guthrie, and other eminent surgeons of the metropolis, as to the most desirable mode of proceeding under her very distressing circumstances. So very inconvenient was the tumour, and so uncomfortable her situation on arriving in London from the ship which had conveyed her from Scotland, that she was obliged to remain at

Wapping, not being able to undergo a conveyance by a coach. Mr. Guthrie visited her at that place, and made a careful examination of the tumour. He subsequently requested Sir Astley Cooper, Mr. Thomas, and Mr. Keate, to examine the swelling, and give their individual opinions as to its nature. Mr. Keate was one of those who were inclined to doubt its being aneurismal. It was however ultimately decided on, with the concurrence of all parties, and under circumstances which imperatively demanded some operation, to cut down on the internal iliac artery, and put a ligature around it.

For this purpose the lady was advised to come into the Ophthalmic Hospital, as it was necessary that after the operation she should be constantly under the eye of the surgeon. Accordingly a suite of rooms were provided for her in the above-mentioned establishment, and on the 24th of August 1833 Mr. Guthrie determined to perform the operation.

Mr. G. here detailed the particulars of the operation, during the progress of which many difficulties presented themselves, and it was found proper to put a ligature around the common iliac artery. The peritoneum was found to be exceedingly thin, not being of more density than common silver paper. On the ligature being passed round the common iliac, pulsation immediately ceased in the tumour. Several sutures were passed through the external wound lest any sudden movement of the patient might cause the internal parts to burst out. Mr. Guthrie remarked in his lecture, that this was a formidable operation, not by reason of the hæmorrhage, but because the external incision was not sufficiently large to admit his two hands. This rendered the operation most difficult. In a case for which he had operated at the Westminster Hospital two years ago, this difficulty did not exist, and the artery was easily exposed and tied. Mr. G. said that in any future attempt to tie the aorta the steps of the operation should be exactly similar to those which he had taken in tying this common iliac artery. He tied the artery within an inch of the aorta, and could have thrown a ligature round the latter with perfect ease, and without any additional trouble.

No inflammation supervened until Sunday evening, August 25th (the day after the operation). The pulse was at that time 120. She was bled to fourteen ounces, and again on the following day to a similar extent. No appearances of mortification in the leg ensued. This Mr. Guthrie attributed to the means employed to prevent such event, and which he particularly recommended. The treatment consisted in the limb being constantly rubbed by two females for several days after the operation. Hot bricks were also occasionally applied. An eminent foreign surgeon, who happened to be in London at the time, expressed great surprise at this treatment, and said that in such cases he was accustomed to sprinkle the limb

with cold water. Mr. Guthrie said he mentioned this, in order to show what difference of opinion existed between surgeons.

Enemata were not given till four days after the operation, when some sulphate of magnesia was administered. The patient soon evinced a change for the better. The tumour diminished in size, and the symptoms of inconvenience very considerably lessened. So improved was she, that she was able to return to Scotland in a coach, and appeared in every respect considerably more comfortable than she had been previous to the operation. These good symptoms did not, however, continue, and she died (worn out by exhaustion consequent on her disease) on the 30th April, 1834, having survived eight months and seven days after the common iliac artery had been tied.

Mr. Guthrie said he was desirous that all mankind should be made acquainted with this operation; and in order that the public might obtain genuine plates of the artery and parts involved in this operation, he has engaged Hummandell, the engraver of Marlborough-street, to strike off a large number of impressions. He himself was at the expense of the stone, and was to receive 500 copies. Every one could thus be supplied with an impression on paying the mere price of the copy.

We shall publish a verbatim report of Mr. Guthrie's lecture in our next.

GUY'S HOSPITAL.

On Tuesday Mr. Aston Key performed three operations. The first was the removal of a steatomatous tumour from the shoulder of a female. Having made a longitudinal incision over the seat of the tumour, he made two or three cuts around the roots of the tumour, and quickly disengaged it from the surrounding parts.

The next operation was the amputation of a leg below the knee, for disease of the ankle-joint. The flap operation was performed on this occasion.

The last and most important operation was the removal of a large portion of the super-maxillary bone, for a malignant disease commencing in the alveoli and extending to the antrum. Mr. Key commenced by making an incision from the right angle of the mouth to the right temple. Then raising up the integument he was enabled to have a full view of the parts. With a forceps he removed several small portions of diseased bone from the lower plate of the right orbit, from the antrum, &c., and, after considerable exertions, succeeded in drawing away a large portion of the super-maxillary bone. The operation lasted about forty minutes, during which time the patient bore his sufferings with the greatest fortitude. The hæmorrhage was excessive, and about six branches of arteries were tied. The operation was considerably impeded by the patient's mouth constantly filling with blood. When all the diseased portions of bone were extirpated, the edges of the two first incision were approximated by five sutures and adhesive plaster. A sponge was introduced into the mouth to absorb the blood, and the patient removed to bed. On visiting him after the operation, we found him lying very tranquil and in every way as favourable as could be expected after such a severe and lengthened state of suffering. Pulse slow. Strong hopes are entertained of the success of the operation, which was the only chance whereby his life might be prolonged.

APOTHECARIES' HALL.

NAMES of gentlemen to each of whom the Court of Examiners granted Certificates of Qualification, Thursday, July 17th.

- William Edward Atkins

Henry Calvert Medcalf

William Angel Silke

Robert Stevens
- { Kimbrige,

{ near Rumsey.

50, High Holborn.

WILLIAM HARRIS and Co.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publisher, 356, Strand, near King's College.

INDEX

TO

THE FIFTH VOLUME.

	PAGE		PAGE
A.		Aneurism of pulmonary artery	61
ABDOMEN , wounds of	641	Aneurism of hepatic artery	197, 358
Abercrombie , Dr., on Apoplexy	808	Aneurism of left subclavian	222
Abernethy's classification of tumours	129	Aneurism by anastomosis	161
Abortion	478	Angina following measles	146
Abscess lumbar	643	Angina tonsillaris , chronic	91
Abscess , chronic	612	Angina membranacea	126
Abscess in perinæo	429	Animalcules , history of	437
Abscess of the uterus	817	Anodynes	685
Abscess external to urethra and bladder	140	Anodynes , use of, in cough and diarrhœa	686
Abscess in thorax	405	Anthelmia spigelia , properties of	340
Abscess in the axilla	669	Antiphlogistics	166
Abscess in the ear	545	Antrum , diseases of	547
Abscesses in the brain	679	Anus , imperforation of—operation	415
Abscesses , milk	611	Apoplexy , 806; cerebritis and meningitis, 806; definition of apoplexy, 806; simple or nervous apoplexy without disorganisation, 807; complicated with other diseases, 807; congestive or serious apoplexy, 808; Dr. Abercrombie's opinions, 808; apoplexy with extravasation, 809; absorption of clot, 810; apoplexy in children	810
Abscesses , scrofulous	97	Apothecaries' Hall , names of gentlemen who have received certificates of qualification, 32, 63, 96, 128, 160, 182, 191, 224, 256, 288, 320, 383, 416, 448, 480, 512, 576, 608, 768, 800	
Absorbents and calcareous medicines	687	Apothecaries' Hall , parliamentary inquiry on	534
Absorption , different causes of	673	Apparatus , new, for fractures	81
Abuses , medical, Lord Brougham on	826	Appointment of surgeon to the Hôpital de la Charité	20
Académie de Médecine	527	Arachnitis , pain of	742
Académie des Sciences	125	Armstrong , Dr., on the Practice of Medicine	380
Academy of Science , election to vacant chair of	207	Arteries , torsion of	83
Acetate of morphia in gastritis	8	Arteriectomy , danger of	713
Aconitine	403	Artery , common iliac, ligature of	831
Address of the Medical Society of Newcastle-upon-Tyne	780	Artery , axillary, aneurism of	796
Admission of air into a vein	61	Artery , hepatic	197, 358
Ague in a child	444	Artery , pulmonary aneurism of	61
Albugo	449	Artery , subclavian	222
Alibert on Diseases of the Skin, translated by S. Plumbe	148, 174, 205, 270	Association , London Medical	23
Aliments , influence of	558	Asthma , new remedy for	18
Amaurosis , or gutta serena	481		
Amenorrhœa	83		
American Cyclopædia of Practical Medicine	695		
Anæmia	61		
Anatomical plates by Dr. Quain	58		
Anatomical Society	817		
Anatomy , Dr. Witt on	59		
Anatomy , comparative, by Sir E. Home	476		
Anatomy of inguinal hernia	709		
Aneurism of the axilla—operation	776		
Aneurism , cases of	412		

	PAGE		PAGE
Asylums, lunatic, laws on	827	Brain, impression on	106
Atkinson's Medical Biography	345	Breast, diseases of	611
Atrophy of the testicle	803	Breast, tumours of	447
Audition through cicatrices in the cranium	18	Breschet et Roussell de Vauzème on the Structure of the Skin	369
Autopsy of a female after coition	721	Bristol surgeons, memorial of	469
Axilla, fatal abscess of	669	British leaf, spurious tea	85
Axilla, aneurism of	796	British Hospital Reports, 31, 61, 92, 158, 188, 220, 255, 286, 382, 446, 478, 479, 702, 734, 766, 776, 829.	
B.		Brodie, Mr., on Hysterical Affections	479
Banner, Mr., reply of	659	Bronchitis, cupping and calomel in	214
Bartholomew's Hospital	223	Brougham, Lord, on dispensaries	826
Bartholomew's Hospital, prizes at	572	Brougham, Lord, on the monopoly of the English Universities	282
Bastardy	696	Brucine and strychnine, efficacy of	519
Baths, iodine, use of	101	C.	
O'Beirne's, Dr., rejoinder to Mr. Salmon	9	Cæsarean operation	561
Belladonna, use of, in calculus, icterus	39	Calculi from the bladder, new method of extraction by the perinæum	818
Bell's, Sir Charles, and M. Majendie's opinions disputed	512	Calculi, biliary	234
Belly, wounds of	641	Calculo-fractor, for pulverising calculi in the bladder	822
Bey, Clot, on Egyptian Surgery	607	Calculus vesicæ—lithotripsy	221
Bignonia catalpa in asthma	18	Calculus vesicæ	191
Biliary calculi	191, 234, 262	Calculus, use of belladonna in	30
Bilious catarrhal fever	530	Calculus, immense	719
Billard, Dr., on Diseases of Children	377	Cambridge petition, Lord Brougham on	582
Birth of a monstrosity	219	Cancer	1
Births and deaths in Paris during the years 1831, 1832	206	Cancer, or occult scirrhus	1
Bismuth, oxide of	8	Cancer, ulcerative stage of	1
Bladder, fungus of	29	Cancer, rarity of, after thirty years of age	2
Bladder, injection of	209	Cancer, fragility of bones in	4
Bladder, puncture of	177	Cancer, causes of	4
Bladder and urethra, diseases of	549	Cancer of the right kidney	29
Bladder, rupture of	140	Cancer, fungus hæmatodes and melanosis	545
Blake, Dr., on Perforation of the Stomach	464	Cancer, encephaloid, of the stomach	543
Blane, Sir Gilbert, death of	730	Cancrum oris, treatment of	246, 747
Bleardness	322	Candidates, admission of at Royal College of Surgeons	160, 288, 479.
Blennorrhagia, M. Ricord on	521	Candidates admitted at Apothecaries' Hall, 32, 63, 96, 128, 160, 182, 191, 224, 256, 288, 320, 383, 416, 448, 480, 512, 576, 608, 768, 800.	
Blennorrhagia, treatment of	273	Caries of the skull—trephining	357
Blisters and leeches, observations on	688	Carnichael, Mr., on mercury	538
Blisters, use of in buboes	147	Cartilages, ulcerated, new cure of	508
Blood, extraction of, at different ages	690	Caruncula lachrymalis, diseases of	259
Blood, circulation of	82	Case of stricture	478
Blundell, Dr., on Obstetrics	441	Castle's Botany	58
Blundell's, Dr., arbitration of, and Mr. B. Cooper, on the question of organic structure of the rectum	10	Cataract, prognosis of	513
Bones, fragility in cancer	4	Catarrhal inflammation of eyelids	321
Bones of the cranium, transmission of sound through	432	Catarrhal fever	530
Books for review, 64, 96, 128, 192, 256, 320, 352, 384, 416, 448, 480, 512, 544, 576, 608, 672, 704, 736, 768, 800.		Catarrho-rheumatic ophthalmia	388
Botany, synopsis of	58	Catheterism, uncertainty of	620
Botany, chair of, at Oxford	601	Catheterism, different modes of	619
Brain, abscess in	679	Causes of dental decay	398
Brain, concussion of	257	Caustic, destruction of strictures by	202
Brain and spinal marrow first formed in human embryo	106	Causes of stricture of the urethra	42
Brain, sympathy of, with thorax	246	Cellular membrane, extravasation of urine into	140
Brain	679	Cephalalgia, attended with vomiting	350, 830
Brain, considered as a secreting organ	744	Cerebral symptoms without lesion found in the brain	317
Brain, compression of	94		
Brain, inflammation of	712		

	PAGE		PAGE
Cerebral affection cured by quinine	444	College of Surgeons	123
Cerebri, hernia of	257	College of Surgeons—List of gentlemen who received diplomas, in Feb., 160; in March, 288; in April, 479;	
Cerebritis, prognosis in	681	College in Pall Mall East, petition of physicians against	28
Cerebritis, general and partial	617	College of Physicians, Cambridge	122
Cerebritis, analysis of symptoms	741, 806	Compendium of Osteology, by T. Witt	59
Cerebritis, symptomatology of, 617; dia- gnosis of, 617; preservation of intellect in	618	Compression and concussion frequently combined	229
Cerebro-spinal system, development of, in infancy	106	Conception, diseases resulting from	147
Cervical ribs, supernumerary	306	Concussion, different stages of, danger of this injury dependent on its original violence	228
Chemistry and Botany, Chairs of, at Ox- ford	601	Congenital club foot	800
Chemical constituents of tea	215	Conjunctiva, scrofulous	386
Chemical changes produced in coffee by sea-water	659	Conjunctiva, granulated	325
Chemosis, treatment of	386	Contagion, a nonentity	507
Chest, danger of wounds of	609	Contagion, origin of	556
Chest, collection of blood and pus in	610	Contagion, doctrine, refutation of, by Dr. Tytler	553
Chevreau, death of	404	Contagion, baneful effects of	558
Cheyne, Dr., on Health	251	Contagious diseases of Europe not con- sidered so in India	556
Children, hygiene and diseases of, 106, 169, 296, 395, 490, 581, 682.		Contraction and paralysis, causes of	678
Children, illegitimate, mortality of	581	Contusion of the brain	817
Children, apoplexy of	820	Contusion, violent, of the face—Necrosis of the os malum	542
Children, diseases of—Sympathy between affections of the thorax and brain	246	Cooper's, Professor, lectures, 1, 33, 65, 97, 129, 161, 193, 225, 257, 289, 321, 353, 385, 417, 449, 481, 513, 545, 577, 609, 641, 673, 705, 737, 769, 801.	
Children, literary education of—Errors in scholastic discipline—Diseases in- duced by	169	Cooper, Mr. B., and Dr. Blundell	10
Chitty's Practical Jurisprudence	723	Copper, colic from	519
Chitty's reply to our review of his book	785	Cork, Medical Association of	569
Cholera, first appearance of in India	554	Cornea, ulcers of	420
Cholera, reappearance of, 800; the writer who first saw it, 554; origin of from vitiated rice, 554; contagion a modern doctrine, 555; not mentioned in the Bible, 555; contrary to the doctrine of the New Testament, 555: not alluded to by ancient medical authors	555	Cornea, opacity and specks of	449
Cholera, reappearance of, in Paris	555	Corneitis, scrofulous	389
Choroiditis	419	Coroners, abolition of	698
Churchill's report of midwifery cases, 777, 778, 779		Coroners' inquests' fees	750
Circulation, influence of pressure upon	82	Correspondence between Mr. B. Cooper and Mr. Salmon	114
Clinical medicine at Vienna	625	Correspondents, answers to, 32, 64, 192, 256, 352, 384, 416, 448, 480, 544, 576, 640, 672, 704, 736, 768, 800.	
Clot Bey on Egyptian Surgery	607	Coster, M., on Créosote	388
Clothing, influence of—Deformity of in- fantile head from compression	433	Crampton's, Mr., clinical lectures	73, 364
Club feet, congenital	800	Cranium, hearing through	18
Cochin Hospital, election at	207	Cranium, infantile, thickening of	81
Codeine, analysis of	404	Créosote, experiments on, by M. Coster	388
Coffee, effects of sea-water on	659	Créosote, therapeutical effects of	783
Coition, autopsy of a woman after	721	Cubebs in gonorrhœa	215
Colchicine, effects of	372	Curious inquiry on infanticide	116
Colic, painters', 485; effects of metallic poisons on the nervous system, 485; symptoms of colic, 486; pathology of neuroses	486	Curious case of apparent death lasting twenty days	818
Colic from copper	519	Cyanuret of potassium, poisonous effects of by injection	502
Colica pictonum	28	Cyclopædia, American	695
College of Physicians, policy of, political influence, illegality of Edinburgh de- grees	25	Cyclopædia of Practical Medicine	696
College of Physicians—Vindiciæ Me- dicæ	473	Cystotomy, demonstration of parts con- nected with the hypogastric operation, 620; description of the perineal re- gion, 621; importance of the diameters of the different triangles, 622; propor- tion of deaths to cures—table, 624;	

	PAGE		PAGE
cases, 624; preparations for the operation of cystotomy	634	Dysentery	137
Cystotomy, different regions for	618	Dysentery, sporadic	164
Cysts in the abdomen and scrotum	60	Dysentery,—treatment—mercurial—stimulating	166
Cysts containing hydatids	162		
		E.	
D.		Ear, diseases of	545
Dashing audacity	251	Ear, inflammation and abscesses of	545
Daturine	373	Eclampsia of infants	576
Davis, Dr., on Obstetric Medicine	57	Ectropium	223
Dawson's Introduction to the Study and Practice of Medicine	541	Eczematoses dermatoses	174
Deaf, number of, in Europe	83	Edinburgh University	88
Death, apparent, for 20 days	818	Education, literary, of children	169
Death of Sir Gilbert Blane	729	Egyptian surgery by Clot Bey—elephantiasis of the scrotum	607
Death from admission of air into veins	732	Electricity, use of, in medulla spinalis	190
Delirium tremens	277	Elephantiasis	800
Deformities by tight lacing	433	Elliotson, Dr., on tobacco injections	167
Dentition and its irregularities, 396; a natural process, and not a cause of suffering unless by parental mismanagement, 397; healthful children do not suffer, 398; national management of	398	Embryo, development of	106
Dental decay, causes of	398	Emetics, doses of	686
Dermatoses eczematoses	241	Emphysema—its dangers, complications, and treatment	611
Dermott's, Mr., defence	437	Empyema—diseases of the lungs simulating hydrocephalus	151
Dermott's plates	437	Empyema after wounds	610
Diagnosis, Dr. Ryan on	296	Empyema of both sides of the chest, cure of	702
Diarrhoea with fever, occurrence of	70	Encanthis, 259; lachrymal passages, 260; stillicidium lachrymarum, 260; epiphora, inflammation of the lachrymal sac 260; treatment	261
Diarrhoea, pathology and treatment of	105	Encephalitis, symptoms of, 677; conclusions as to contractions and paralysis	678
Diarrhoea, diopsy, death	530	Encephalitis, diagnosis of, 644; preservation of function with organic disease, 644; vicarious action of parts, 645; importance of pathology to phrenology	646
Digitaline	473	Encephalitis, remarkable cases	679
Digestibility of aliments, as introduced through an opening in the stomach	483	Encephalitis, 712; treatment of, in the adult, importance of energetic means, 712; dangerous effects of opening the temporal artery, or jugular vein, 713; employment of cold, good effects from purgatives, 714; encephalitis caused by piles, 714; treatment of—blisters, beneficial effects of, 714; mercury, dangerous effects of—Dessault's treatment of, 715; use of opium, 716; violent counter-irritation in coma, 716; application of barley-water	716
Dilatation, enormous, of the stomach, vomiting for 30 years	543	Encysted tumours—setons	348
Diseases of the small intestines	69	Enlargement and irritability of the mammae	128
Diseases, frequency and symptoms of, in children	71	Enteritis simulating cerebritis	680
Diseases caused by utero-gestation	147	Enteritis with diarrhoea	104
Diseases, contagious in Europe, 556; non-contagious in India	556	Entropium	324
Diseases, contagious, denied	553	Epidemic, bilious	528
Diseases, infantile, lectures on	399	Epidemic diseases	553, 556
Diseases, etiology of	399	Epilepsy—tumours in dura mater	317
Disease resembling phthisis	657	Epilepsy from tumours, Hôtel Dieu	351
Dispensaries, Lord Brougham on	582	Epsom salts, new method of administering	824
Dispensaries, self-supporting	434, 727	Epulis	578
Distichiasis	324	Erysipelas of the leg	767
Donation to the Royal Institution, Westminster Medical Society	342		
Dothin enteritis	40		
Dropsy, ovarian	373		
Drugs, adulteration and exposure of, before parliament	631		
Dublin Journal of Medical and Chemical Sciences, No. XIII.	210		
Dublin Journal	508		
Dumb and deaf persons, number of, existing in European states, table of	83		
Dupuytren's, Baron, lectures	618, 717		
Dupuytren's, M., clinical lectures, 477; erysipelas—abortion, 478; sprain on both sides of the face, and abortion	478		
Dymock, Dr., on Supernumerary Ribs	306		

	PAGE
Erysipelas, simple, 174 ; phlegmonous and oedematous erysipelas, 176, 222 ; etiology of erysipelas, 177 ; its treatment	177
Erysipelas phlegmonodes, and amputation at the shoulder-joint and across the foot, 430 ; of the face	478
Erysipelas, gangrenous, death	629
Erythema, etiology of, 205 ; epidemic and endemic forms, 205 ; treatment of the different kinds	206
Etiology	242
Etiology, or causes of infantile diseases	319
Evolution, spontaneous	23
Exorbitance of medical fees	666
Extraction of a stone from the bladder, weighing two pounds six ounces	719
Eye, diseases of, ophthalmia, 353 ; treatment of inflammation of the eye—simple or catarrhal inflammation of the conjunctiva, 354 ; the distinction between this and other species of inflammation, 354 ; Egyptian ophthalmia, 355 ; its treatment, 356 ; purulent ophthalmia of new born infants, treatment of, 356 ; gonorrhœal ophthalmia in the acute form	357
Eye, malignant diseases of	545
Eye, its appendages, disease of	258
Eyelids, encysted tumours of	322
Eyelid, eversion of, 323 ; inversion of, 324 ; catarrhal inflammation of	321
Eyelid, concretion of	325
F.	
Face, diseases about	546
Fallopian pregnancy	350
Fees, exorbitance of	666
Fecundity, influence of the seasons on	582
Females, superabundance of in polygamous nations	583
Femur, congenital luxations of	471
Fever, catarrhal	630
Fibro-cartilaginous tumour	132
Fingers, permanent retraction of	500
Fistula lachrymalis, cure of, by perforation of superior maxillary bone	691
Fistula, perinæal section in	372
Fistula, salivary	547
Fœticide, curious inquiry on	116
Foreign Medicine—maladie de bright, 243 ; extracts from the Life of Cuvier, 243 ; researches upon croup	244
Fractures, treatment of, by an immoveable apparatus	81
French hospital reports	28, 60
Functions and development during infancy and childhood	395
Fungus hæmatodes, 545 ; amputation at the shoulder-joint	732
G.	
Gall-bladder, rupture of, after use of emetics	263
Gall-bladder, distension of, 54 ; diagnosis of, 327 ; its causes	327

	PAGE
Gall-bladder, puncture of	327
Gall-stones	191, 234, 262
Galvanism against the bite of a viper	49
Gangrene of the liver	328
Gaspard Hauser, life of	668
Gastric irritation in warm climates	233
Gastritis with delirium tremens	421
Gastritis, chronic, treatment of—friction with croton oil	37
Gastritis, chronic, treatment of, 5 ; fre- quent excitement of the vascular system necessary to the performance of the functions of the stomach, 6 ; local bleeding, 6 ; regimen, 6 ; counter-irritation over the stomach, 7 ; treatment of Broussais	8
Gastro-duodenitis	229
Gestation utero, diseases of	147
Gestation, tubal	350
Glandular system, inflammation of	139
Glans penis, ulceration of	223
Glasgow Royal Infirmary	412
Glasgow and St. Andrew's	282
Glaucoma	419
Gleet, treatment of	43
Gonorrhœa, effects of cubeba in	215
Gout in the penis	277
Grando, or Chalazion	322
Graves, Dr., on the modern German works	441
Graves's, Dr., operation on the liver	361
Green, Mr., on Medical Reform	315
Green's, Mr., intended plan of reform	283
Gregory, Dr., and the Westminster Me- dical Society	313
Growths, adventitious	129
Guinea worm in the thigh	432
Gums, diseases of	578
Gum-boil	578
Gun-shot wounds, clinical remarks on	503
Gun-shot wounds of the thigh	542
Guthrie's, Mr., lectures, 41, 138, 201, 266, 330, 426, 650, 831, 549	
Guthrie, Mr., evidence of	437
Guthrie, Mr., on the prostate	650
Gutta serena	481
H.	
Hall, Apothecaries', certificates granted by 32, 63, 96, 128, 160, 191, 224, 256, 288, 320, 383, 416, 448, 480, 512, 576, 608, 768, 800	800
Hall, Apothecaries', parliamentary in- quiry on	534
Hæmatorax	601
Hæmatocele	94
Hæmaturia	267
Hæmorrhage, fatal, from a varicose vein	722
Hæmorrhage from the bladder	267
Hæmorrhage, uterine, Mr. Latham on	693
Hand, sanguineous tumour in the	381
Hare-lip and cleft palate	382
Harrison's, Dr., general infirmary	435
Head, infantile	
Head, wounds	
perforial injury	

	PAGE		PAGE
scrapulas following injuries, 194 ; treatment of suppurating wounds of the scalp, 198 ; fractures of the skull, fracture without depression, 195 ; trephining in such cases seldom necessary, 195 ; symptoms and treatment	196	Hernia, anatomy and surgery of, by Mr. Tuson,	441
Head, injuries of, 225 ; trephining, opinions of Mr. Abernethy on, in what cases the operation is necessary	225	Hernia, strangulated, spontaneous cure of	29
Health, general rules for the preservation of	596	Hernia, strangulated umbilical	701
Health, influence of, on procreation	583	Hernia, cerebri, nature of, 257 ; treatment of	258
Heart, rupture of	208	Hernia of the lachrymal sac	291
Heart, sounds of	308	Hibiscus esculentus, preparation of	81
Heart, diseases of	53	Hip-joint, injury of, 159 ; disease of, cured by mercury, 536 ; cases of, by Dr. O'Beirne and Mr. Carmichael	538
Hemeralopia and ague in a child	444	Home, Sir E., comparative anatomy	476
Hemiplegia during pregnancy	694	Homœopathic system, suppression of, at Vienna	51
Hepatic neuralgia	393	Hooping-cough, treatment of	408
Hepatitis, chronic treatment of, 389 ; connexion of hepatic with gastro-intestinal disease, 391 ; modes of transmission of disease from the mucous surface to the liver	391	Hôpital Cochin, election at	207
Hepatitis, chronic and acute, 292 ; pathological differences, effects of climate, general and local symptoms, 293 ; character of fever, pain of shoulder, use of pleximeter, 294 ; complication with jaundice, 294 ; resolution—abscess, 295 ; various openings of the latter, 296 ; cicatrization	296	Hôpital de la Pitié	90
Hernia, 705 ; hernial sac, meaning of, 705 ; difficulty of defining hernia, 705 ; varieties of, 706 ; causes of hernia, 706 ; general symptoms of, 707 ; reducible, irreducible, and strangulated hernia, 707 ; treatment of, 708 ; taxis, employment of, 708 ; anatomy of inguinal hernia, 709 ; direct and oblique hernia,	711	Hôpital Militaire d'Instruction d'Alger	91
Hernia, strangulated, treated by the extract of belladonna	732	Hôpital du Midi	60
Hernia, case of	735	Hôpital of la Pitié, reports from 60, 29, 318, 350, 477, 543	
Hernia, different manœuvres of operating, 737 ; operation for strangulated femoral hernia, 769 ; methods of different surgeons, 770 ; various seats of the stricture, 770 ; Sir Astley Cooper's plan, 770 ; recommendations of his hernial bistoury, Dupuytren's method and knife, Hesselbach's plan, 771 ; congenital inguinal hernia, 771 ; its formation, 771 ; hernial sac with its contents sometimes descends into the tunica vaginalis, 772 ; cystocele, symptoms of, 774 ; operation for aneurism of the axilla, cure, 796 ; operation for external inguinal hernia, 737 ; operation for the direct or internal inguinal hernia, 737 ; operation for complete laceration of perinæum, 812, 814, 816	816	Hôpital de Treviglio, reports from	30
Hernia, umbilical, strangulated	711	Hôpital Militaire de Calvi	191
Hernia, strangulated, with perforation of the intestines	90	Hôpital de la Charité, reports from	218, 381
Hernia, crural strangulated, operation	158	Hôpital de St. Louis, reports from	357
